From such conditions as those outlined in the foregoing, and those cases coming up occasionally where the compressor fails completely, we investigate further as to cause and remedy, and find that most of the low efficiency and some of the failures are due to lack of repairs, or to the quality of the repairs made being below, though often only slightly, the standard required. In some cases it is an error in a single particular, but more often in a combination, such as a number of leaks, any one of which may be too slight to cause trouble, yet when combined becoming serious. The above applies more particularly to compressors having steam and air cylinders compounded, on account of the balancing effect that may be caused by leakage.

It is not uncommon to find a compound compressor that is chronically inefficient, and be advised that one part after another has been repaired or replaced, until all or nearly all of the working parts have been gone over, and yet the operation is not improved. Some such cases are a matter of record, where a careful inspection showed everything in fair condition, except the high pressure air piston rings were 3-16 to 5-16-inch open, or rings in both high and low pressure air pistons 3-16 to 1-4-inch open when in the smallest part of cylinder, of rings in some of the pistons of the main valve 1-8 to 3-16-inch open

FIG. 9—SHOWING HOW TRIMMING OPERATION WAS ACCOMPLISHED.

Thickness of Plates, and Riveting of Stacks

The Common Guyed Steel Stack is the One Under Discussion—This Subject is a Bit of a Mystery to the Average Person; and Should be of Particular Interest.

By JOHN S. WATTS

THIS article deals only with the common guyed steel stack, and not at all with the self-supporting stack, as the former has not been usually designed at all, but built by rule of thumb, with a consequent wide variation of practice in the thickness of plate used. I have seen all kinds of riveting from 2" pitch up to 12" pitch. The lack of any data published on the life of these stacks has led me to gather up the information collected over a number of years, to try and arrive at some more dependable method of specifying the scantlings required than has been in vogue in the past.

My reason for not including the design of self-supporting stacks is that this problem is pretty well understood, and is really a very different affair, and is therefore not touched upon in what follows.

The first point to be decided upon is the thickness of plate to be used, and while it is well known that a new stack of any thickness almost will stand the wind pressure, until quite badly corroded, no attempt has been made, so far as I know, to determine the thickness required to carry the wind pressure, and to resist corrosion over a pre-determined number of years.

In a guyed stack, the stresses are analagous to those in a beam uniformly loaded, and supported at each end, the load being the wind pressure, and the stack being supported by the foundation at the bottom end, and the guy ropes at the upper end.

D. K. Clark, in his book "Rules, Tables and Data," gives a formula for thin hollow tubes, as beams supported at both ends and loaded in the center, which agrees very closely with the results of experiments made by Sir William Fairbanks on tubes having dimensions similar to those of the stacks we have under consideration.

This formula is

$$W = \frac{3.14 \times D^3 \times T \times S}{l}$$

Where W = Load in pounds
D = diameter of tube, outside, in inches
T = thickness in inches.
S = Stress in pounds per square inch
l = length between supports in inches; in our case this is the length from the foundation to the guy band.

That portion of the stack, above the guy band, being a cantilever, uniformly loaded, will be equal to the other portion of the stack in strength, if made one-fourth of the length of the stack between the foundation and the guy band. For very high stacks two or more sets of guy bands may be used, and, l is then tween the foundation and the guy band.

In the case of a stack, the load to be carried is that due to the wind pressure, and is uniformly distributed, and therefore the load that can be supported will be double that given in the above formula, which considers a concentrated load. We therefore change the formula to read

$$W = \frac{6.28 \times D^2 \times T \times S}{l}$$

It will make it more convenient to use the length, L (which is in inches), in feet, so making L = the length in feet between supports, we have

$$W = \frac{6.28 \times D^2 \times T \times S}{12 \times L}$$

The wind pressure is generally taken as 56 pounds per square foot as a maximum, and in a round stack, the effective area against which this pressure will act as half the diameter, multiplied by the height, both in feet. The load W will then be

$$W = \frac{D}{12} \times L \times 28$$

Substituting for W, in the beam formulae, we get

$$W = \frac{6.28 \times D^2 \times T \times S}{12 \times L}$$

$$\therefore \frac{D}{12} \times L \times 28 = \frac{6.28 \times D^2 \times T \times S}{12 \times L}$$

$$\therefore T = \frac{\frac{D}{12} \times L \times 28 \times L \times 12}{6.28 \times D^2 \times S}$$

$$= \frac{L^2 \times 28}{6.28 \times D \times S}$$

Taking the safe stress to be 16,000 pounds per square inch, and substituting in the above formulae, we have

$$T = \frac{L^2 \times 28}{6.28 \times D \times 16{,}000}$$

$$= \frac{L^2}{3589 \times D}$$

To the thickness given by this formulae must be added a sufficient amount to cover the loss by corrosion, which may be expected to take place during the number of years which it is desired the stack should last.

Under average conditions, burning soft coal with natural draft in a fairly pure air, and the stack having received one shop coat of graphite paint and, another coat of paint just previous to erection, the plates will corrode away at a rate of about .01 in. in thickness per year. In very close proximity to the sea this rate will be increased to about .013 in. per year.

If the stack could be repainted once a year, the life of the stack would be about doubled, but the expense of erecting staging to do this painting, which must be done both inside and out to be of any benefit, is prohibitive.

It will, generally speaking, be found cheaper to make the plates of a thickness that will give a life of ten to twelve years as at the end of that period it is very probable that a larger stack will be required to take care of an increase in the boiler plant.

The actual thickness of plate to be employed, then, will be = T + (.01 in. × the number of years of life required).

Experience has shown that the plates do not corrode under the rivet heads, nor do the rivets themselves waste away, it is therefore not necessary to have the riveting any stronger than a solid plate would be of a thickness = T.

The actual thickness of plate used, being designated as P, the required efficiency of the riveted circumferential joint, to equal the strength of the calculated thickness of plate T, will be

$$\text{Eff} = \frac{T}{P}$$

The diameter of the rivet used must be such that the bearing surface of the plate, on the rivet, will be sufficient in area to develop the full shearing strength of the rivet. Taking the safe bearing stress as 24,000 pounds per square inch, and the safe shearing stress as 12,000 pounds per square inch, the diameter of the rivet being d, the safe load on one in single shear will be $d^2 \times .7854 \times 24{,}000$; and the safe load on one rivet in single shear will be $d^2 \times .7854 \times 12{,}000$.

$$\therefore d^2 \times .7854 \times 12{,}000 = d \times P \times 24{,}000$$

$$\therefore d = \frac{P \times 24{,}000}{.7854 \times 12{,}000}$$

$$= P \times 2.55$$

The required efficiency of the joint being that of the rivets in single shear, will be

$$\text{Eff} = \frac{d^2 \times .7854 \times 12{,}000}{\text{Pitch} \times P \times 16{,}000}$$

$$\therefore \text{Pitch of rivets} = \frac{d^2 \times .7854 \times 12{,}000}{P \times \text{Eff} \times 16{,}000}$$

$$= \frac{d^2 \times .7854 \times .75}{P \times \text{Eff}}$$

(Continued on page 265)

Reducing the Cost of Locomotive Repairs*

The Subject of Cost is a Vital One in Any Business, But Especially so in a Railroad Shop—The Subject of Repairs, While an Unpleasant One, Must Be Met.

By S. W. MULLINIX

MATERIAL represents approximately 40 per cent. of the cost of repairing and maintaining locomotives, a large percentage of which is purchased either rough or finished, and owing to the high cost of labour and the absence of modern and special production machines in many railroad shops, there are many articles which can be purchased in a finished condition more cheaply than they can be manufactured by the railroads. There are also many articles and tools sent from the purchasing to the mechanical department to be tested out to see how they compare with home-made articles and tools, as well as to compare with similar articles from other manufacturers. These tests should be given careful consideration, as they very often decide a standard for the entire system. and sometimes what is considered a successful article or tool in one shop is complained of by another. For that reason, when an article is being tested it should be gone into thoroughly, having competent employes pass on it.

Were one to stop and figure, one would be appalled at the cost in dollars and cents of the unnecessary labour which is wasted on material such as hard castings, requiring twice as long to finish, or the many hours of labour that are wasted on some pieces of material that turn out to be full of blowholes or cracked. They may have been passed on by the test department, but no matter how efficient the inspectors are, they will not find all of the defects, especially in our rough material. Even though defective material is replaced by the manufacturers, they do not pay for transporting back and forth to the store department, and from there the handling to the shop and back, nor do they refund the amount spent for labour in the shop.

The mechanical department should work very closely with the store department on unsatisfactory material, calling attention promptly to any article that is not standing up or giving the service that should be expected, so that they can get in touch with the manufacturers for correction.

Locomotive Cost

During the war period the locomotive cost has also been greatly affected, due to shortage of material, making it necessary to substitute all classes of material. The mechanical department is to blame, to some extent, for this condition, due to the changing of patterns and specifications, which at times may be a paying proposition, but it tends to discourage the store people from carrying any large amount of stock. The mechanical department is also responsible for the great number of parts which the store is compelled to carry in order to supply the various styles and types of equipment, such as air brakes, injectors, safety valves, and lubricator parts. It would be far cheaper to scrap the obsolete equipment, replacing with standard material, which will give better results and reduce the number of repair parts to be carried in stock. We must check over our material and equipment, simplifying stocks wherever possible, and we must not merely go over them once and then sit back and imagine that the job has been completed. It never will be as long as we operate railroads.

Another very expensive practice is the robbing of material from one engine for another. We not only pay for removing and replacing the part removed, but the chances are that it will cost more to apply the piece removed than it would cost to apply a new one. Each of these items traced down will disclose that if someone, whoever he may be, had been on the job it would not have been necessary. A large percentage of the material which we use does not give the service that should be expected, on account of extraneous conditions. For instance, a piston rod may be packed half-a-dozen times, never getting it tight on account of imperfect rod, or guides not being properly lined. Had the trouble been found out in the first place and corrected, it would have saved five sets of packing and the cost of applying. This applies to many items used on locomotives.

Material, where carried in stock by the store, should not be ordered before it is to be applied, especially small finished parts, as they will be thrown about and either broken or lost, necessitating ordering other pieces, which will double the cost. Shop people should be more familiar with the cost of different items of material which they use, as it is surprising to many good railroad men to know just what many small items really do cost, and probably they would think twice before throwing old parts away and putting on new ones.

Another item of material where the quality has a great deal to do with the cost is in connection with the painting of locomotives. for no matter how carefully or how scientifically it is applied, poor paint will not give good results, and will have to be removed much oftener than good paint. We are not merely painting our locomotives, especially our freight engines, with a view to beautifying them, but to preserve the material. An old coat of good paint is much better than a new coat of poor paint.

We have the opportunity to be far more efficient in the handling of material than with labour, as the human element does not enter into it to any great extent, and if we watch more carefully the things which we scrap there would not be so much material to reclaim, for the more lax we are in scrapping material the better showing the reclamation department can make.

Manufacturing Locomotive Parts

The use of forging machines in the blacksmith shop has worked wonders in the way of producing forgings which require very little or no finish, such as small side-rods, eccentric rods, motion work, spring hangers, and yokes, large hexagon nuts, and like material. Many large shops to-day are equipped with modern forging machines, which with the proper dies are a great help in reducing costs, as many of the parts now made require very little finish, where formerly they were finished all over. Blacksmiths have a great chance these days to do their work so as to eliminate finish. For example, in main and side-rods centre sections may be forged to size, requiring no finish except where the rods are channelled. Guide blocks can also be forged so as to require no finish except where they fit on the cylinder heads and the face for the guides and yoke. Guides should be forged so as to eliminate as much finish as possible. Parts such as piston rods and valve stems should be cut to the proper length. Wedge bolts should be forged and ends squared, so that all that is necessary to complete them is to thread them in a bolt cutter. These were formerly made from bar stock on turret machines. Eccentric blade forks, ends, and jaws for other motion work should be made allowing finish only where they fit on to the links—outside contours may be ground off. Eccentric blades for outside valve gears should be forged, allowing finish only on the sides, on the back end and for the link fit on the front end. Large hexagon and castle nuts should be forged and holes punched allowing very little finish. There are many other items where finishing can be reduced or eliminated, and, naturally,

*Proceedings of the Western Railway Club.

the less the number of operations necessary to produce a finished part, the less the cost will be. Dies for this work are very expensive and should be well taken care of, as they will pay for themselves many times over.

Castings

Patterns should be changed so as to reduce or eliminate finish where possible, and changed from brass to cast iron or steel or from cast iron to steel where parts are apt to break. If it is absolutely necessary to use brass, use it; if not, use either cast iron or steel, but no matter what is used no more finish should be called for than is absolutely necessary. We are using many castings in the rough to-day which a few years ago we thought necessary to finish all over, such as side-rod collars, other collars for motion work wedge-blocks, and collars for main rods, front and back ends, also for strap middle connections, and many other small castings. Finish may be reduced on parts such as cast-iron piston heads, allowing finish only on the outside for cylinder size, and the inside for the rod fit. Front cylinders and valve heads may be cast with finish for the joint only. Core slots in driving-box wedges for wedge bolts to size, and maintain one standard for all wedges. All grate, side, and centre bars and supports, ashpan and grate shaker-rigging castings should be cast ready to apply on engines with all holes cored and all castings the proper size and shape. The use of good metal patterns is a help in securing good castings of the proper size and shape, as they will not warp or twist out of shape, and once they are made right they will always be that way. Eliminate as much as possible finish on whistles, cab fixtures, blow-off cocks, boiler checks, cylinder cocks and valves, bells and yokes, relief valves, parts for piston and valve-stem, packing, oil cups, swab holders, grease cups and plugs. Many of these items are used in large quantities, and every little saving that can be made will help to reduce the cost.

Where it is necessary to finish castings or forgings, enough allowance for finish should be made, as it is much cheaper to remove ⅛-inch than to just scrape off the sand or scale.

Reclaiming Material

Wonderful progress has been made in the last few years in the way of reclaiming material. Although the results will not be so noticeable in the next few years, they will be as good at least, as a more careful study is being made of the things which might be reclaimed, as well as of the new places where reclaimed material can be used. At Silvis we are making many special machines, such as rattlers for cleaning nuts and other small material, cutting shears and machines for straightening iron, special cutters for cutting gaskets and washers from old leather and rubber. The electric and acetylene welders have also worked wonders in the way of reclaiming. Most of this material is reclaimed after reaching the scrap dock, and is handled in most cases by a special reclamation department.

There is another side to the reclamation question, one which is not so often heard of. This is the reclaiming of material such as broken parts on locomotives without removing them, or by removing, reclaiming, and replacing on the same engine they were removed from. In most cases this is done with either the electric or acetylene welders. There is very often a close margin between the cost of reclaiming some certain piece and purchasing and applying a new one. In these cases we should apply the new piece, as too often in figuring the amount which we save we colour the figures to make them look as attractive as possible, or to otherwise try to make a good showing, without taking into consideration the life or wearing qualities of the piece we reclaim against that of a new one.

We must guard against letting our enthusiasm get the better of our good judgment in the things which we reclaim. Unquestionably, there are parts being reclaimed to-day at a loss, both in material and in labour. Other cases will actually show a great saving. Where parts, such as piston rods, valve stems, and other like material have been reclaimed by building up for fits, they should be properly annealed before being turned to fit. Where rods or stems are worn near to the scrapping limit, or to the age limit, if we have one, it is not advisable to attempt to reclaim them. The practice of welding small broken cast-iron parts which, in the first place, do not require much finish, is not worth the chances one takes in getting a good weld. In many cases new parts will be just as cheap and much better.

Looking back through the years one can plainly note the progress made day by day and year by year—made possible both by more modern machines and tools and by improving the methods of doing work. Still progress has not kept pace with the modern locomotives, which are not only much larger, but are equipped with modern appliances, such as mechanical stokers, super-heaters, feed-water heaters, brick arches, and power reverse, all of which add to the cost of maintenance. The average cost of repairing engines has increased year by year, but by united effort it should be possible, by more efficient methods and practices, to stop its upward trend, which is necessary before we can hope to reduce it.

Thickness of plates and riveting of Steel Stacks.

CONTINUED FROM PAGE 263

To illustrate the mode of procedure we will take a concrete example, say a stack 40 in. diameter by 100 feet high, to last an estimated time of twelve years.

As explained above, the length of the stack from the foundation to the guy band should be four times the length of the stack above the guy band, the length L will therefore be four-fifths of 100 feet, that is, 80 feet. Substituting in the formulae we have $T = \frac{L^2}{3589 \times D}$.

$$\therefore T = \frac{80^2}{3589 \times 40}$$
$$= .044 \text{ in.}$$

For corrosion during twelve years, we must add .01 in. $\times$ 12 = .12 in., making a total of .044 in. + .12 in. = .164 in.

The nearest gauge to this is No. 8 B. W. G., which is .165 in.

The efficiency of the joint, which will be required to equal the strength of a plate .044 in. thick, will be

$$\frac{.044}{.164} = .268$$

The diameter of the rivet will be

$$d = P \times 2.55$$
$$= .165 \times 2.55$$
$$= .4207 \text{ in.}$$

which will call for a $\frac{7}{16}$ in. diam. rivet hole.

The pitch will be

$$\text{Pitch} = \frac{d^2 \times .7854 \times .75}{P \times \text{Eff}}$$
$$= \frac{.4375^2 \times .7854 \times .75}{.165 \times .268}$$
$$= 2.54 \text{ in., say } 2\tfrac{1}{2} \text{ in. pitch.}$$

While this riveting is only necessary at the points of maximum bending moments, it is probably as cheap to make the riveting uniform throughout as it would be to having wider pitches at the points of lower strain.

The rivets in the vertical seams have no other function to perform except that of holding the joint together without openings that would leak air into the stack, and a pitch of sixteen times the thickness of the plate will answer the purpose well.

In a paper read before the American Chemical Society at St. Louis, Jerome Alexander recently announced the discovery of a new fuel fluid, greater in heat value than either coal or present fuel oils. He asserted that the fluid would prove valuable to navigation, permitting a wider cruising radius, and could be used for smoke screens. The new fuel utilizes coal waste and cheap tars.

Evolution of the Electric Brass Furnace

Electric Crucible Furnaces and Overhead Resister Furnaces Are Discussed in This Interesting Paper which Was Presented Before the American Electrochemical.

By H. M. ST. JOHN

AN electric furnace classification is based, as a rule, on the difference of method utilised for the application of heat to the material under treatment. In this case the species are three:

The induction or direct resistance furnace, in which heat is generated in the metal itself by virtue of its own resistance to the passage of an electric current.

The arc furnace, in which heat is generated between an electrode and the metal, or between independent electrodes, and transferred to the metal by conduction or radiation, direct or indirect.

The indirect resistance furnace, in which heat is transferred from an incandescent resistor to the metal by conduction or radiation, somewhat as in the arc furnace.

All of the electric furnaces so far proposed for melting brass naturally fall in one of these classes, or a combination of some two of them.

In the beginning the would-be inventor of an electric brass-melting furnace was obsessed by the idea that such a furnace should bear a close resemblance to the combustion furnaces then in use for that purpose. In the electric crucible furnace as in the fuel-fired crucible furnace, the heat must, in general, be generated at some point outside the crucible and transmitted to the metal through its walls. A favorite suggestion was to surround the crucible with an electric resistor of granular nature, which was heated to incandescence by the passage through it of a suitable electric current.

Most of these fundamental difficulties were obviated by using a resistor which surrounded the crucible but did not come in contact with it. In this way the heat generated in the resistor was first transmitted to the crucible by radiation, and, finally, by conduction through the walls of the crucible to the metal.

To the writer's knowledge, the only furnace of this type which was ever operated with any degree of technical success was equipped with wall resistors of thin carbon slabs, provided with means of variably adjusting the contact pressure between the slabs. The generation of heat in this furnace depended, not on the resistance of the carbon itself, but in the contact resistance between the slabs which could be varied at will in auch a way as to provide an excellent means of controlling the current and voltage, and thus the rate of power input. Despite its good qualities, it was soon apparent that this furnace could never be commercially successful. Its maintenance cost, both for carbon electrical parts and refractories, was a serious handicap, but more serious still was the fact that its thermal efficiency was inherently and irremediably low.

The latest proposal to melt brass in an electric crucible is one which has recently been very thoroughly described and discussed, in which the metal within the crucible is heated by a high-tension, high-frequency induction or eddy current. The walls of the crucible itself are electrically conducting and serve to heat its contents during the period while the metal is still solid and in pieces not in good electrical contact with each other. Most of the disadvantages already described as characteristic of the crucible furnace have been overcome in this design. This new type has, however, so far been built in sizes more suitable for the laboratory than the foundry.

The low thermal efficiency of crucible furnaces heated from without naturally suggested the possibility of utilizing the walls of the crucible itself as a resistor. This principle was tried out quite thoroughly rather early in the development of electric furnaces for melting brass. In one type the crucible was built of a special mixture with suitable electrical conductivity, but no attempt was made to insulate the walls of the crucible from the metal which it contained. In another design this feature was taken care of by means of special insulating lining separating the conducting walls from the metal. It proved almost impossible, however, to maintain this insulating layer, and short circuits invariably resulted.

Overhead Resistor Furnaces

Not all, even of the early experimenters, limited their attention to the crucible furnace. The advanages of a larger furnace capacity and the elimination of crucibles were sufficiently obvious, and had already resulted in a considerable use of various types of direct-flame oil and gas furnaces. The earliest attempts to melt brass electrically in a furnace of this sort made use of an incandescent resistor supported above the bath and radiating heat directly to the metal. This construction, applied to an open-hearth furnace of small capacity, gave rapid melting and a fairly high thermal efficiency. The principal difficulties were two; the development of a resistor which would stand up continuously under the required conditions without an excessive maintenance cost, and the invention of some reliable method for supporting the resistor in the desired position over the bath. Neither of these basic problems has ever been adequately solved.

The difficulties which interfere with the use of an overhead resistor are partially avoided if the resistor is located above the bath, but at either side or surrounding the central portion of the melting chamber. One well-known type of furnace now in commercial use employs this principle, utilizing for the purpose a granular resistor contained in a nearly circular refractory trough. This trough is exposed to very severe usage, since the resistor temperature must be much above that of the molten metal. The roof also is at a temperature considerably in excess of that of the metal, and must be highly refractory. Another type of furnace which is in somewhat limited commercial use employs a combination of granular resistor and smothered arcs at either end of the melting chamber. In this type also most of the heat must first be radiated to the roof and then to the metal.

A high thermal efficiency was early recognized by investigators in this field as an absolutely essential qualification for the permanently successful electric brass-melting furnace. It semed obvious that if some practical method could be devised for generating heat in the metal itself, conditions most favourable for a high efficiency would be produced. The celebrated pinch-effect phenomenon is too well known and has been too often discussed to require definition here. The pinch-effect can be utilised to increase substantially the electrical resistance of molten brass through which a heavy electric current is flowing. This was done with considerable success in designing the first practical direct-resistance furnace for brass. It has recently been proposed to change the construction of this furnace in such a way as to eliminate the massive metallic electrodes.

The elimination of electrodes from the design of the direct-resistance furnace was evidently of the highest importance. This was done in a somewhat later type of furnace by constructing it as a vertical-ring induction furnace with the resistor channels jointed at the bottom to form a complete circuit for the passage of electric current. The limitations of the vertical-ring induction furnace are due, first of all, to the fact that it is an induction furnace, and, as such, cannot be constructed in large sizes without introducing electrical disadvantages such as low power factor.

Furnaces of the Arc Type

The widespread success of the arc fur-

naces in the melting of steel was not overlooked by those more particularly interested in the brass industry. Many attempts were made to apply both direct and indirect arc furnaces directly to the melting of brass, without changing the design which had been found most suitable for steel melting. These attempts were pretty uniformly unsuccessful, because copper and its alloys—particularly the high-zinc alloys—suffered under the direct application of such a high temperature heat source as the electric arc.

A great deal of study was devoted to the discovery of some method which would make possible the utilisation of th good features of the electric arc for brass melting. The direct type of arc furnace was evidently out of the question. In the indirect arc furnace, overheating was less localised. It seemed probable that if the metal could be stirred with sufficient vigour, the entire bath could be maintained at a uniform temperature, and tendency toward local overheating could be entirely neutralised. It was found by experiment that rocking the furnace mechanically, at the rate of approximately two oscillations per minute, resulted in a degree of agitation ample to maintain complete uniformity of temperature throughout the molten bath, and that the obvious advantages of the arc furnace could be utilised in this way without the slightest injury to the metal, even in the case of alloys containing 40% or more of zinc.

The so-called rocking electric furnace resulted from this development and is in wide commercial use at the present time for melting all classes of copper alloys, as well as copper itself. As in the induction furnace, the vigorous stirring of the metal results in a uniformity of temperature and of composition throughout the alloy, a feature which is of particular importance in the melting of high-lead alloys.

The pronounced success of the rocking type of arc furnace has prompted many suggestions for modified designs, similar to it in principle but differing from it in details of construction. For example, it has been proposed to rotate the furnace body instead of merely oscillating it.

The evolution of the electric brass furnace has now proceeded to such a point that fundamental improvements in design are henceforth likely to be rather slow to materialise. There will, of course, be constant progress in the development of refinements in mechanical and electrical design, calculated to make the furnaces more reliable, more durable, and more nearly foolproof than they are at present.

This brings us to a brief consideration of what the brass-foundryman can expect and ought to realise from the use of electric furnaces.

The first and probably the most important point is the saving of metal—commonly wasted during the melting process—which electric melting makes possible. If the charge to be melted consists of new metal or clean scrap, the net metallic loss during melting and pouring from the furnace should not exceed 1 per cent. for yellow brass and 0.5 per cent. with red brass. With clean yellow brass, containing 40 per cent. of zinc, losses as low as 0.75 to 0.85 per cent. have been experienced as an average for a considerable tonnage of metal melted. In melting a scrap charge containing a high percentage of non-metallic, such as oily borings, chips, grindings, etc., the net loss should not exceed 2 per cent.

It is also true that the furnace which melts without agitation is not particularly well suited for melting a charge which contains a high percentage of finely divided, dirty scrap, while these can be handled without difficulty in either induction or rocking arc furnaces. Brass melted in the electric furnace is practically free from metallic-oxide drosses and has no opportunity to pick up sulphur or other contamination from combustion gases.

The consumption of electricity energy under average conditions of 8 to 10-hour operation is as low as 240 kw.-hours per net ton for yellow brass, and 275 kw.-hours per ton for red brass, in the induction or arc furnaces. In 24-hour operation figures as low as 200 kw.-hours per ton or less have been obtained. Less efficient furnace types use from 400 to 500 kw.-hours per ton, depending upon conditions.

Flexibility, which in this case may be defined as the suitability of a furnace for radical changes in operating conditions or for an abrupt change in the composition of the alloy to be melted, is a marked characteristic of the resistance and rocking arc furnaces, which is notably lacking in the induction furnace.

The net melting cost, considering all factors which should properly be considered under this head, is naturally lower in those furnace types which melt the metal most rapidly and efficiently, since their use of electric energy is more economical and their higher rate of production reduces the fixed charges per ton of metal melted. In many cases the cost of electric melting is not more than half the cost of melting the same alloy in combustion furnaces. Even in the less efficient furnace type, electric melting is usually less costly than the older methods.

Electric brass melting can no longer properly be called "the coming thing." It has arived in a most convincing fashion, as is evidenced by its rapid adoption by the larger and more progressive rolling mills, foundries, and manufacturing establishments which use brass in large quantities.

ADJUSTABLE TAPER GAGE

The Knauel Tool Works of Rock Island, Ill., have brought out an adjustable gage that may be quickly set to any desired taper and locked in position. These gages are only made in the open size but will cover a wide range of taper work.

GRAPHITE IN CANADA

A report on graphite, just published by the Mines Branch of the Department of Mines, contains a wealth of information on the subject of this interesting and important mineral. The report is written by Mr. H. S. Spence, mining engineer of the department, and treats of the properties, occurrence, distribution, mining, and uses of graphite in a most comprehensive manner. Interesting information is given on the present status of the graphite industry in Canada, and on the outlook for the industry as it is likely to be affected by foreign competition.

The report points out that Canada possesses deposits of flake graphite superior in richness and quality of flake to any on the American continent. What is probably the largest and richest deposit of flake graphite known in the world occurs in Ontario, and is worked by the Black Donald Graphite Company of Calabogie. Difficulties of concentrating and refining the graphite, however, have long hampered operators and have mitigated against the establishment of a flourishing industry. Quite recently these difficulties have been overcome by the employment of the oil-flotation system of ore concentration, which yields far better results than were obtainable by the old methods, both in the richness in carbon of the concentrates made and in the amount of graphite recoverable from the ore treated. Several Canadian mills have now been equipped with the above flotation process and are producing refined graphite equal, if not superior, to the best graphite on the market.

Crucibles used in the melting of steel and alloys consume a large proportion of the graphite produced, and other important uses are in lubricants, paints, foundry facing, pencils, stove polishes, dry batteries, dynamo and motor commutator brushes, electrodes, and boiler scale preventives. In all, about 50 different uses of graphite are listed in the report, which, in addition, gives much interesting information on the methods of manufacture of a number of the more important graphite products. The report consists of about 200 pages, and is profusely illustrated with photographs, drawings, and maps. Copies may be obtained by application to the Director, Mines Branch, Department of Mines, Ottawa.

Montreal.—Another addition to the fleet of the Canadian Government merchant marine will be made about the middle of this month when the complete "Canadian Runner" will be turned over to the company by the Canadian Vickers, Ltd. Launched on May 8, 1920, from the yards of the Port Arthur Shipbuilding Company, the vessel is of 4,350 deadweight tons, and had to be cut into two sections to come through the Lachine Canal. The bow section is already at Vickers and the stern is expected to arrive to-morrow. She should be ready to sail, probably for the United Kingdom, about the end of the third week in September.

Industry's One Law "Be Square With Your Men".*

Lasting Success Only Attained by Understanding and Utilizing Human Element in Accordance with Principles of Justice—Scientific Achievements Heralded, While Greatest Forces Have Not Been Cultivated.

By ERNEST E. BELL

INTEGRITY of purpose coupled with ability for accomplishment, or the lack of these, I doubt not, influences the fixing of credit with everyone of you more often than does the financial statement. In taking a broad survey of industry generally and casting a balance of assets and liabilities for industrial progress, we find one of the most important, if not the most important factor, to be the human element. That industrial institution which under present conditions fails to realize this fact and grasp the fundamental principles upon which the human element can be utilized for industrial progress, regardless of its financial statement, is neglecting to cultivate one of the most important factors for future profit.

An appreciation of this fact, with intelligent inquiry into the attitude of management toward labor, and the attitude of labor toward that particular management, is becoming of more and more importance to the banker and those entrusted with the fixing of credits. It is to be hoped, however, that those responsible for extending financial support to industry will not satisfy themselves with inquiry into these relationships, but will inform themselves as to the fundamentals underlying right industrial relationships, so that they may intelligently awaken and guide effort in this direction.

It all resolves itself, in the final analysis, into a question of human relationships, and the question of human relationship is as old as the Garden of Eden. As between man and woman, it started when Eve asked Adam to partake of the apple. As between men, it was raised, and has been a question since Cain inquired, "Am I my brother's keeper?" As a factor in industry it has existed since the herdsmen of Lot had strife with the herdsmen of Abraham on the plains south of Bethel and since Pharaoh's taskmasters required the children of Israel to make bricks without straw.

As for you and me, our earlier teachings of love, sympathy and kindness were gained at our mother's knee, while our impressions as to right conduct and punishment for wrongdoing were received over our father's knee. Such thinking as we may have done since has been influenced very largely by these early impressions, and whether the teachings of our mother or the experiences with our father in the woodshed have predominated, depends somewhat upon the kindness or justice with which these were administered.

Human relationships find expression through family ties, through friendships, through contacts which result from the performance of our daily tasks. Systems of government have been established in an effort to control and co-ordinate human action and protect human rights. Men differ in their opinions as to personal rights and as to forms of government. But the most rapid advances of civilization and industry are recorded under those forms of government which, within proper limits and with justice to all, have permitted of individual initiative and action. The principal effort of every human being is to find contentment and happiness, and here again men differ in their conception of what is required to produce contentment and happiness. But the majority of men have concluded that true contentment and happiness are not to be found in the acquisition of material wealth at the expense of others nor in the wielding of political or industrial power for purely selfish ends.

It has been said that all men are born free and equal. That all men do come into this world with equal right, and should have equal opportunity for the pursuit of liberty and happiness, is unquestionably a right premise. But whatever their right we certainly cannot agree that man's opportunity is equal, and even if it were all men are not born with equal ability to succeed, nor with equal capacity for appreciation of the many and various purposes for which individuals may rightly strive. St. Paul tells us that some are born to prophesy, some to preach, some to teach. And the greatest Teacher of all ages tells us that there shall always be rich and poor, masters and servants, those who exercise authority and those who submit to authority. But this same Teacher gives justice, kindness and love as the controlling factors in all human relationship. He condemns with equal emphasis oppression by those in authority and disobedience on the part of those who should serve.

Improvement in forms of government undoubtedly is possible and betterment in industrial relationship should come with it, but the lessons which we draw from the wisdom and experience of the past lead to the inevitable conclusion that there must be an authority with power to direct action; that individual capacity plussed by individual effort will make for individual advancement, and that all individuals are not equal in natural capacity nor is their willingness to make sacrifice and to wisely apply their effort. Some men, therefore, will outstrip their fellows and thus will acquire advantages and benefits, to which they are rightly entitled, but which they must use with the true spirit of consideration for the rights of others and not for the unjust exploitation of those less fortunate.

Regardless of forms of government men are contented and happy only when they have opportunity for individual expression in effort, when they are free to apply themselves, with proper reward, to the limit of their natural capacity. It is this that makes industry, and industry creates those things which minister to the physical necessities of humanity. Unless work is rewarded by a fair return for effort, and to be a fair return it must be sufficient to provide for the normal necessities of the individual and those dependent upon him, no form of government is sufficient to guarantee the happiness and contentment of the human race.

Industry, therefore, as it provides opportunity for individual effort and accomplishment, becomes of paramount importance in human relationship and to human happiness. Industry started when God found Adam clothed in a fig leaf, led him to the nearest exit from the Garden of Eden and told him to go out and earn his bread by the sweat of his face.

But man can never escape his responsibility for individual effort—work—and to the extent that we try to escape that individual responsibility will we find discontent, want and distress of every character. For the past four or five years most of the civilized world has devoted its energies to destruction instead of industrial construction—the result largely of mutual reaction from oppression. In the utilization of material forces men have learned to study and recognize natural laws. But in human relationships we seem to have overlooked the natural laws of cause and effect, of action and reaction. Where oppression is the cause the effect must eventually be the reaction which we now witness in Rusia, which tears at the very foundations of civilization by the roots, turns order into chaos and makes men reckless in their strife for the recogni-

*Address delivered before the Pittsburgh Association of Credit Men. Ernest E. Bell is vice-president of the Hydraulic Steel Co., Cleveland.

tion of those things which they demand as natural endowment.

Less Thought Given Human Relations

Man seems to have acted with less intelligence in conducting human relationships than in the subjugation of material elements. He seems to have given less thought and less study to the natural laws which control humanity. Just as water can be utilized for power through recognition of the natural law of gravity, so can the power of the human race be developed and utilized only when we recognize the natural endowments of mankind and operate in accordance with them. In our relationships with family and friends we recognize a natural law of love, and through acts of kindness show appreciation of this natural attribute and produce a reaction of like character. When we step out of the family into industry we seem to assume immediately that this natural attribute of the human race fails to exist and apparently set ourselves to operate upon the theory that all men are selfish, exclusively selfish, and through operating upon this basis, produce only selfishness as a reaction.

Seek Cause for Dissatisfaction

Scientists, psychologists and economists have taken up the study of this problem in an effort to find the cause for dissatisfaction in the industrial relationship between individuals and classes. An article recently appeared in one of the national weeklies which gave some very interesting data in regard to the reaction of certain laborers to music. It said that some who gave no evidences of refinement, without education, who were seemingly capable of only the most ordinary tasks, showed marked appreciation for music of a high order, and left noon hour concerts with tears of emotion in their eyes, as they thanked those who had provided this pleasure and diversion for them.

Another experience is that of a steel company which is making intelligent effort to interpret right relationships between employer and employe, to gain the confidence of their men by, perhaps, unusual methods. This company has secured one of the best artists in the country to produce paintings of men and factory scenes, some of which are reproduced in their plant publication. This artist tells of a common laborer, a roustabout in the steel mill, who looked over his shoulder one noon hour as he tried to portray on canvas the molten metal flowing from an open-hearth furnace. The man said to the artist, "You paint God." In surprise the artist inquired what he meant, and the laborer went on to express in broken English his idea that God is in the hot metal, God is in the iron, God is in nature. And this artist has had a lot of experiences, which show that under any spark-burned flannel shirt beats a heart which is full of sentiment.

Sociologists have stories to tell of the reaction which comes from kindly deeds, performed not as acts of charity but of common justice, and in such manner as to recognize the self-respect of the individual, from which they conclude that regardless of employment, environment or the station of life in which the individual may be found, the same human impulses actuate all mankind. Science through continuing this effort eventually may make the unique and remarkable discovery that the human race is human; that there is in the hearts of men those things which God originally planted there, sympathy, kindness, love, and that these will react to sympathy, kindness and love. But when the psychologists, the sociologists and the scientists get through, if their science leads to right conclusions, they will go back to the teachings of the Carpenter of Nazareth and proclaim in unison that the only right basis for human relationship is to "do unto others as you would have others do unto you." And when men learn to treat with each other on that basis there will be no difficulty in the reconciliation of differences in industrial life.

But, you say, this is sentimentalism, and there is no room for sentiment in business; that the function of business is to acquire gain, and that its very character, therefore, makes necessary the elimination of those human attributes, in the full expression of which we find pleasure and satisfaction in the intimate relationships of family and friendship. Let us look at this problem, considering business from the most selfish and narrow standpoint, as being the art of acquiring gain in worldly goods. To this end we employ our every energy and seek out every element which can be utilized for the accomplishment of this purpose. The most important of these is the human element. From a purely selfish standpoint, therefore, it behooves us to study the natural laws through which the full potential power of human endeavor for industrial progress will be released.

Natural Laws Aid Progress

Man's abiilty to use material forces is dependent upon his ability to understand and recognize natural laws. We recognize the natural law of gravitation in damming up streams for the creation of power. Men of unusual ability, of particular training and knowledge, have spent decades in an effort to learn the natural laws through which the power of electricity can be utilized. But have we used the same intelligence in our study of the human element as we make effort to utilize its power for industrial progress? Conditions today in industry give positive answer. Industry in many parts of the world is paralyzed, and in our own country is suffering to an extent from which it will take years to recover, for the very simple reason that we have not understood the handling of men; have not applied ourselves with the same degree of intelligence to a study of human attributes and the proper treatment of human beings as has been used in the study of material forces for their utilization. Our very selfishness has reulted in a reaction of selfishness, and industry and individuals are now paying the price, not only in discontent and unrest, but in dollars.

If men react and become more constructively useful through our giving consideration to the human attributes of love and kindness, then from the most selfish standpoint of individual gain we can find no excuse for refraining from giving full expression to these sentiments in our industrial human relationships. Did the lords of Russia who practiced oppression during decades and centuries past act with far-sighted wisdom from a purely unselfish standpoint? No, and against them must the indictment be drawn for the present destruction, which is nothing more nor less than reaction from centuries of injustice and oppression. And we may well consider against whom our children and our children's children will draw the indictment, should our failure to properly conduct ourselves in human relationships in industry result in destructive reaction in years to come. Possibly this is sentimentalism, in that it treats with attributes of sentiment, but in the last analysis it is only commercial self-interest, because it makes for the utilization of the potential power of the human element in industrial progress and for protection against that destruction and loss which reaction from opposition to natural laws must and inevitably will bring about.

This does not necessarily mean that business is to become a love feast or a Sunday School picnic. "Business is business" and doubtless always will be. But it may be good business for us to pause long enough to think seriously of these matters from a purely business standpoint; to make an inventory of business generally; to face without prejudice the debit and credit columns of those factors which advance or retard constructive progress; to let our vision extend beyond our own profit and loss statement for this year in protection of right profits in years to come.

It may not be expedient to give expression to love and kindness in the same manner in business as we express these feelings in the family circle or with intimate friends. Men do not expect kindness to find expression in business through the giving of something for which an adequate market return is not required. In fact, they resent such an attitude as has been shown where so called welfare work has been attempted with kindness as the only compelling motive. But where kindness has resolved itself into sincere interest in the other fellow's well-being and is expressed in terms of justice and not charity, better relations have been and are being

established. And this is true because there is in every human being an instinct which demands the recognition of self-respect and this self-respecting individual says: "I don't need your kindness in the form of charity. Give me justice in the right spirit and I ask no more." And whether men realize the fact or not, few indeed, fail to appreciate and react to conduct which finds its impulse in recognition of the principles of the golden rule and in an effort to observe those principles.

This also is human instinct which demands the privilege of self-expression and it is this instinct which causes men to resent and resist ready-made plans which are handed down by well-meaning but misguided ownership; plans toward the forming of which labor has given no thought and in the carrying out of which it has no function. We are perfectly willing to have an architect draw the plans for our new home, but every member of the house likes to be consulted before the plans are finally approved. If each one of us, therefore, will consider the other fellow as having the same human attributes as we and accord him the same treatment to which we would naturally respond were our positions and conditions reversed, reactions from such conduct would soon adjust all differences. Men only want to be treated human, not humane.

The leader of a labor union came into my office some weeks since and asked in connection with some statements which had been made over the signature of our company, just what we meant by management having an equal responsibility to capital and to labor. In reply I asked him, "Just what do you mean by capital?" His statements indicated that he looked upon capital as that vague, intangible, unapproachable, unpreachable, inhuman power, which is labor's enemy, and the sole purpose of which is to exploit labor. With evidence of this mental attitude on his part, I inquired if a fair definition of capital would not be the conservation of energy, and used this illustration: "All men have been enjoined to work, to exert the energy, physical or mental, with which nature has endowed them. Let us turn two men loose in the wildnerness. One applies his energy to clearing off a patch of ground, to building a cabin, to getting a garden started, so that he may have food for the winter, to make provision generally against future needs. When winter comes he has a warm cabin, plenty of firewood and plenty of food. He has built up a reserve to make him comfortable. The other, instead, spends his time in loafing, hunting and fishing a little when he is in the mood. This is all very well for the summer, but when winter comes, will he not find himself some cold morning knocking at the cabin door of the man who worked and conserved, asking for a handout and a place to warm his feet? The first man has simply created capital in the form of those things which protect him against want. The second man has failed to do so.

The Lesson of Tony and Mike

"And to bring the illustration a little nearer to present day conditions: Tony and Mike started to work in a steel mill some years ago. They both started on the same day and at the same rate of pay as laborers in the yard. Tony was an energetic worker and applied himself to his task. When the day's work was done he used to go home to his family, conserving his energy for the next day's work. He always managed to save something out of his pay, and by taking care of his physical welfare, he made himself an increasingly valuable man. Within a few months he asked the foreman of the yard how he could fit himself for a better job. The management provided opportunity for Tony to get a better education by studying nights. In the course of time he became a unit boss. His increased pay enabled him to lay by a larger amount in the savings fund, and when the company gave an opportunity for employes to buy stock Tony had a cash down payment ready and got hold of a block of stock., In the course of time Tony became a foreman. He had bebecome a capitalist through his investment in the company's stock, and when he was taken sick and died, it was with the thought that his wife and family were cared for through this stock which had been acquired by his thrift and conservation. Mike shirked his work from the first day. He just about held his job. His evenings, as well as his pay, were spent in the saloons. Physically, he became less capable every year. He still works as a roustabout in the yards, but he is not nearly as good a man to-day as he was 10 years ago. And he hasn't saved a cent."

At this point I asked, "To whom does the management of the company owe the greater responsibility? To the capital created through Tony's energy, represented in the stock which he left for the protection of his family, or to Mike who failed to conserve his physical energies or the result in pay which they produced?" You can guess his answer.

So, when actual human relationships as to cause and effect are pointed out, and it is realized that capital, whether in large or small amounts, is simply the accumulation of conserved energy, which comes from somebody's application, hard work and ability to save, labor would, indeed, be unreasonable did it not recognize the responsibility which management has to those who have acquired capital in this manner. But labor is resentful at being oppressed in order that great accumulations of capital may be accomplished, and rightly so.

And thus the greatest differences which exercise humanity to-day, those existing between capital and labor, may be reasoned out and reconciled if we but approach this problem in the right spirit. If we will subject it to the same analysis of cause and effect, of action and reaction, as we apply in the utilization of material forces, both capital and labor inevitably will come to see that difference in station and accomplishment are not differences which necessarily lead to controversial strife. The unreasonableness in men is very largely reaction from the unreasonable manner in which they have been treated, whether capitalist or laborer. Industry is suffering on account of our having forgotten or failed to recognize the humanity of the human race, on account of our having acted upon impressions which were gained in the woodshed entirely, and having overlooked those other more important attributes which were the basis of our mother's teachings.

And what are we going to do about it? The Almighty, for the preservation and development of civilization, has in His wisdom implanted certain instincts in the human soul. They constitute the most potent force in the whole scheme of creation, and until these human impulses have been released, so that the human element in industry may extend itself naturally, labor is no more able to relieve its own unrest than the fever patient is to reduce his own temperature without the cause having been removed.

We can no more change the instincts with which the human race has from the beginning and will until the end of time come into the world than we can cause water to flow uphill. Man has learned to utilize material forces through studying natural laws and adjusting his operations to certain fundamental principles which nature has prescribed. Why, then, is it not good common sense, good business, for us to study the natural forces which control humanity and so adjust our thinking and our doing that industry may benefit in full measure from the power for progress which is to be found in the human element? We don't fight natural forces, but adjust ourselves to natural laws in the utilization of material elements. And until industry shall have learned that all human beings are fundamentally the same, that all characteristics which prompt human action and stimulate human endeavor, are fundamentally the same, differing only in degree, and shall appreciate this fact and recognize it in human relationships, industrial unrest will never be quieted and labor will never be satisfied regardless of the hours of toil, the rate of pay or the cost of living which are offered.

There is no single influence in industry to-day which more quickly changes the balance sheet or more vitally disturbs credits than misunderstandings and strife between those who apply their dollars and those who apply their skill and brawn to industrial progress. Inventories of raw materials accumulate and lie dormant instead of being fabricated into finished product and converted into the wherewithal with which to pay bills. And this may be true, not because of differences at that particular plant, but for causes which have their origin

in other plants, possibly in other industries, and not unlikely in other cities. Our process of industrial development has brought about an interweaving and an interdependence of interests which has wiped out industrial and geographical boundaries.

You pay a high price for flour in Pittsburgh, while wheat rots in the elevators of the great Northwest. Your warehouses are filled with finished product, ready for shipment, and your banks find it difficult to supply the capital with which to keep industry going. These specific instances are due very largely to differences which have arisen between individuals in the transportation industry. If transportation had not been interrupted, the wheat from the Northwest ere this would have reached the consuming market; dollars which have been sent from the East to carry this grain in elevators would be in circulation and your stores of finished product would have been converted into cash.

It is confidence that lubricates the wheels of industry; it is confidence upon which credit is based, but until confidence shall have found expression in right relationships between so-called and miscalled "capital" and "labor," it will be impossible to establish that uninterrupted flow of commodities upon which all credits depend and through which obligations are liquidated.

NOT SATISFIED WITH OUTLOOK

Increase in Miners' Wages Has Resulted in Decrease in the Output

Roy M. Wolvin, president of the Dominion Steel Company, returned to Montreal from a trip to the Maritime Provinces, where he inspected the company's plants and conferred with the officers in charge of its steel and coal activities.

"The steel works at Sydney are at present very prosperously employed and working to full capacity," Mr. Wolvin stated. "We have plenty of orders ahead, and, taken altogether, the outlook is good. Production at the coal mines, however, is disappointing, due in large measure to the fact that the miners are taking many summer holidays, while there is a feeling of restlessness abroad, while waiting for the report of the Royal Commission now investigating conditions in Nova Scotia."

Mr. Wolvin expressed the view that, owing to the conditions existing in the country at the present time, and with the cost of living on the decline, together with the prospect that there would be considerable unemployment during the winter, the commission could not with consistency recommend an increase in wages. The investigation of that body, he stated, would undoubtedly show that the increased wages granted during the past three years had generally resulted in a decrease in the output of coal at the mines.

WAR CONTRACTS IN THE COURT NOW

Dominion Steel Was Ordered to Roll Rails and Stop Its Work On Munitions

Ottawa.—That the condition of Canadian railways was such in the early months of 1918 as to justify the Dominion Government taking steps that practically stopped the making of steel for shells by the Dominion Iron and Steel Company in order that rails necessary for renewals might be rolled was shown in the hearing of the case of the Dominion Iron and Steel Company versus The King, which opened in the Exchequer Court.

The point at issue was the price the company thought should be paid for 116,000 tons of rails rolled and delivered subsequent to April, 1918, by the steel company, the rails being furnished in consequence of an order in council passed by the Government under the authority of the War Measures Act enjoining the company to supply at least 100,000 tons in order that the railways might be put in a position to operate up to full capacity during the period of the war.

The cause of the difference of opinion as to the value of the rails, it developed during the hearing, was that when the Government order was issued the Dominion Iron and Steel Company had in hand large orders from the Imperial Munitions Board for shells, and the manufacture of these had to be practically discontinued, with the result that 99,000 tons were not delivered. On behalf of the company it was stated that for this steel the company would have received about $80 per ton, but cost of production would have exceeded the cost of making rails by from $3 to $5 per ton.

CAN'T GET RAILS TO PUT DOWN TRACK

So Building of Many Branch Lines Has Been Held Up For the Present

Ottawa. — Difficulty in securing supplies of steel rails and also shortage of labor are assigned as causes of little progress this year in projected construction of branch railways. The Canadian National had planned to take up slightly-worn main line rails and use them for branch extensions, replacing them with heavy 85-pound rails; but the latter cannot be secured save with great difficulty and delay, and, as a result, branch line work, especially in the West, has been retarded.

There is likewise a shortage of railway labor due to the fact that Canadians do not take to that kind of work, while thousands of foreigners who used to do it went home during or after the war, and have stayed there. Others have gone to the cities. As the urban labor markets are becoming slack, it is hoped that in these quarters the necessary men may soon be secured for railway extension and maintenance.

BALDWIN'S READY IN SHORT TIME

Ready to Go Ahead With Production of Material at Toronto Plant

"Baldwins, Limited, hope to have eight mills in operation within two months, all at Ashbridge's Bay," Sir George Wright, vice-president of the company, said as he was leaving Toronto for England. Sir George has been in Toronto for several weeks organizing the plant.

"We have sufficient electric horse-power from Niagara to run the eight mills," said Sir George, "and we have been assured by Sir Adam Beck that within the next year we will be able to obtain sufficient power to run any extensions that we may care to make.

"We intend to put down sufficient mills to supply the whole of Canada with black plates, tin plates, galvanized sheet metal and black sheet.

"I have been very much impressed with the help that Mr. Cound, our general manager, has received from the people of Canada. The working people of Canada seem to take a great interest in the plant.

"Like everywhere else, it is true here that the only way in which a plant may be successful is by the help and support of the people who work with us."

Baldwins, Limited, have purchased several reducing furnaces at Collingwood, which they are moving to Toronto.

RAILWAY RATE INCREASES AT A GLANCE

	Eastern Canada	Western Canada
Freight Rates—		
September 13 to December 31	40%	35%
January 1	35%	30%

Coal increased 10 to 20 cents ton. Fuel wood, 10%. No increase on milk, sand, gravel, crushed stone.

Passenger Rates—		
September 13 to December 31	20%	20%
January 1 to July 1	10%	10%
July 1	Return to present rates	

Increases not to exceed 4 cents per mile. No increase on commutation fares.

Special Services—	
Sleeping and parlor car rates	50% increase
Excess baggage	20% increase

Switching, demurrage, stopovers, weighing, etc., must be made basis of special application.

Did You See Mechanical Drawings at the Ex.?

J. H. Moore.

IT may be possible that many visitors to the Exhibition at Toronto this year have missed the excellent display of mechanical drawings, owing to their peculiar and unsuitable location.

The majority of these drawings are the work of railroad shop apprentices, and the students are to be highly commended upon their work. A wide variety of subjects are covered, and the writer noticed that these included the following:

Drawings of valve motion, section of locomotive boiler, steam pump, model beam engine, air compressor, steam engine, locomotive cylinder details, locomotive inspirator, section of pneumatic drill, electrically driven pump, pneumatic hard grease press, steam hammer, pneumatic motor, and quick action triple valve.

Other subjects were hydraulic wheel press, hydraulic piston remover, control panel for electric welding and cutting, suburban type locomotive, duplex pump, flanging press, electro turbo generator, and a set of lever shears.

All drawings showed signs of promise, while some in particular were almost without fault. The chief features to the writer's mind were the neatness of arrangement, and careful workmanship throughout.

Quite a number of contestants won prizes for their efforts, and as it was impossible to secure the names of all those exhibiting, we will speak only of the prize winners. These prizes were divided into certain sections, so that when you read of various first prizes being awarded you will understand we speak of prizes for the different sections.

First Prizes

The lucky artists to land first prizes are as follows: W. Grandison, G. T. R. shops, Stratford, Ont., his showing being a splendid drawing of a duplex pump; E. T. Driver, of Toronto, won first prize by his drawing of a continuous current generator, while Arthur Sansfacon, of the C. P. R. Angus shops at Montreal, landed a first prize for his splendid drawing of some columns of the Corinthian order. Frank Brown, of Toronto, got first prize for his showing of the Gloucester Cathedral cloisters. The two latter drawings were, of course, architectural.

Second Prizes

The gentlemen who came close seconds and who captured the coveted blue tickets, were as follows: A. T. Dutand, G. T. R. shops, Montreal, got his prize for a view of a suburban type locomotive. Another G. T. R., Montreal, man to land a second prize, was L. A. Tugeral, a pair of lever shears being his exhibit.

The judges evidently felt some special prizes should be awarded, and C. Kyle, C. P. R. shops, Montreal, and E. Harris, G. T. R. shops, Montreal, were the fortunate ones. The former secured his prize for a showing of locomotive 2,300, while the latter displayed a neat flanging press. It might be well to add that C. Kyle also won another second prize in the architectural class by an exhibit of some columns of the Corinthian order. J. B. Helme, of Toronto, landed a second prize for a neat drawing showing the east entrance of the main building of the University of Toronto.

From the foregoing one can see that quite a number of prizes were given and well they deserved them. In some cases the drawings were colored with different shades of ink, making a rather pretty effect. In practically all drawings appearance was aimed at from the border lines in.

Help Them Along

It is very encouraging to see such a display of earnest effort by the apprentices in the railroad shops in particular. The executives who have the destinies of these young chaps in their hands are to be congratulated on the splendid showing of their boys, and if all apprentices in the machine tool line could do equally as well, it would tend to raise still further the present standing of the machine tool business.

We were rather disappointed on not seeing some efforts by the students of our various technical schools. but perhaps by next year we will have that pleasure. We feel sure there is plenty of hidden talent in our many technical and evening classes, and would suggest that the teachers of such classes encourage their students to prepare work for next year. It is also to be hoped that by the time the next exhibit is due, the place of location will have been changed to one of more suitable locality, such as the machinery hall.

MAINTENANCE OF AIR COMPRESSORS

Continued from page 262

and a poor fit in the grooves, and when these are properly repaired the compressors work all right.

What Examination Proved

In one case an 8 1-2-inch cross compound compressor developed pounding, would not supply sufficient air, and the engine had to be taken off an important train. Examination showed that the rings in both the high and low pressure pistons were 3-16 to 5-16-inch open at the ends and lacked about .012-inch of filling the ring grooves. New rings that would fit the cylinders, but were .012-inch smaller than the grooves, were applied to both the air pistons, and the compressors gave good service for four months, and probably longer, but records do not show.

Still another. An 8½-inch cross compound compressor pounded some, and ran so slow with 190 pounds steam pressure that it would not keep up 90 pounds standard brake pipe pressure on a regular passenger train of ten cars, against normal leakage. Examination showed:

(a) Main steam and air cylinders slightly worn. (b) Steam cylinder head parts in good condition. (c) Main steam and air pistons about 1-32-inch smaller in diameter than their cylinders. (d) Packing rings in steam and air cylinders came together at ends in smallest part of cylinders and were a little less than 3-32-inch open in largest part of cylinders. (e) Rings lacked .005 to .008-inch of filling grooves in high pressure steam cylinder. (f) Rings in low pressure steam cylinder lacked .012 to .015-inch of filling grooves. (g) Rings in high pressure air cylinder lacked .015 to .018-inch of filling grooves. (h) Rings in low pressure air cylinder lacked .012 to .015-inch of filling grooves. (i) Upper final discharge valve had a 3-16-inch lift, one upper intermediate valve had 7-32-inch lift and other air valves had only slightly more than standard lift.

New pistons that would fit the cylinders closely at the smallest part, and in which the rings fitted the grooves with just enough clearance so they would expand by their own tension when compressed into the grooves, were applied and no other repairs made, and the compressor given a severe running test in which its capacity and speed developed were fully up to standard.

Recommended standards to cover repairing and adjustment of the different parts of compressors have been extensively published and discussed ever since the cross compound compressor came into use, but general observation would indicate that these are not taken seriously and appear to be seldom considered in connection with compressor repairs and maintenance. On account of this, the general standard of service of these compressors is considerably below what may reasonably be expected and what may be obtained by uniformly raising the standard of quality of work done in maintaining them, which may be done at slightly increased cost, and by simply following standards such as those outlined in recommended practice by the Air Brake Association.

The Northwest Air Brake Club believes that it is time for a general awakening to the need of progress and improvement along these lines, and that the logical and most effective means of bringing about such improvement is through the influence of the Air Brake Association and the air brake clubs throughout the country. The number of engine failures chargeable to the air compressor alone indicate the need for improved compressor maintenance. and the other troubles that can readily be traced directly to a lowered compressor efficiency emphasize it to a high degree.

WHAT OUR READERS THINK AND DO

SHORT CUTS

By Fred Horner

The following hints, or short cuts, will no doubt be of interest to the readers. Some may know of them, then to others the schemes will be new. The first idea is shown at A. This really gives two suggestions for set-screw guards, to those who do not care much about hollow set-screws. In the first instance the idea is to thread the neck of the dog, and screw upon it a stout steel tube. The other notion also incorporates a renewal, when the thread in the dog has worn badly. Bore the neck out and thread afresh to a larger size. Then screw in a renewal bush which is extended into a protective tube. A socket wrench is used to operate the screws.

The next scheme is shown at B. This depicts a miniature bolt driver.

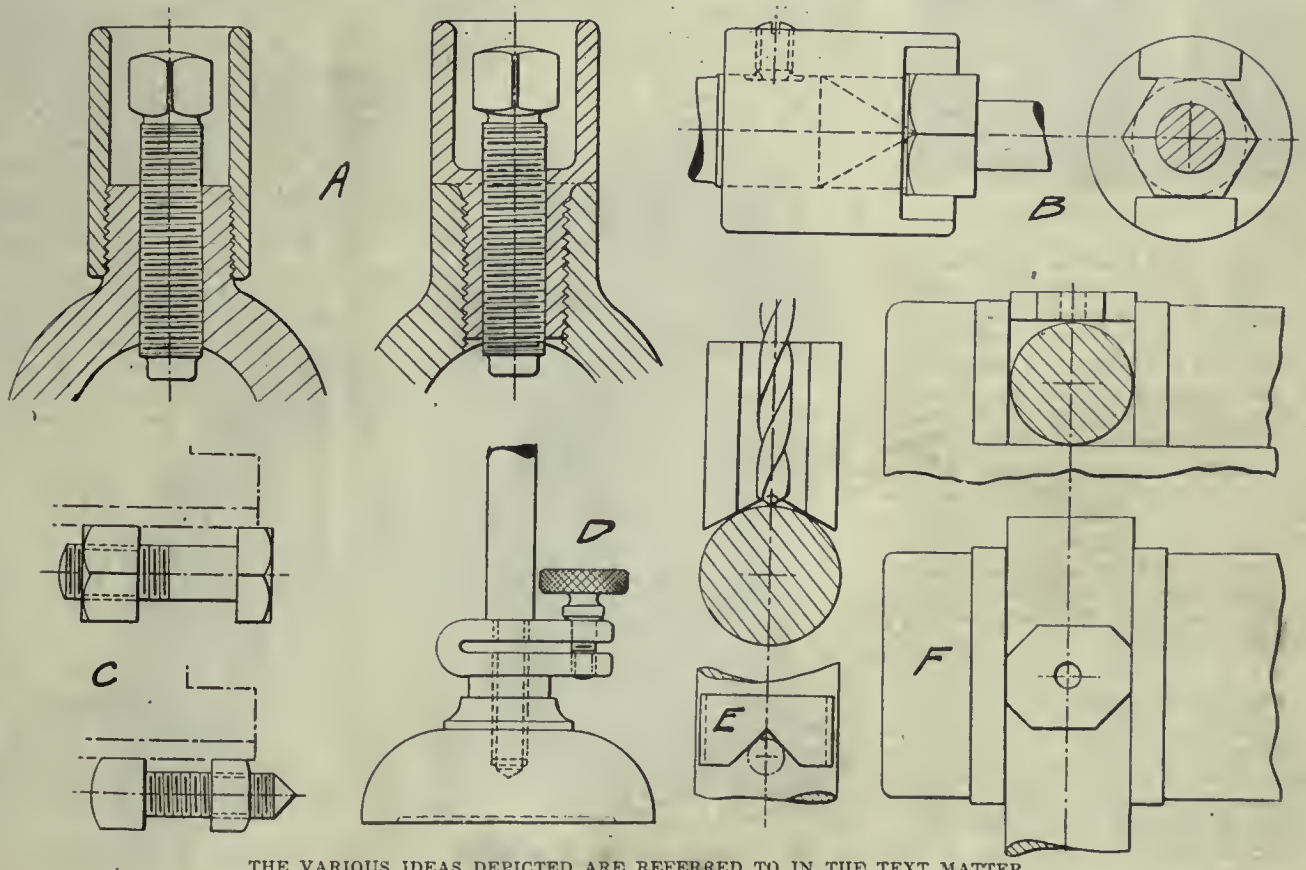
When small bolts or other flatted pieces have to be driven between centres, a useful driver may be made in the manner shown. A piece of stock is bored out to slide snugly over the centre, and is locked thereon by a grub-screw bearing upon a flat. The nose of the fitting is slotted out suitably to embrace the head, the sharp corners left from the slotting being preferably removed as shown.

The third suggestion is shown at C. In this case nuts are used to aid in the chucking of screws. In any case where small bolts or screws have to be chucked for thinning, trimming, chamfering or pointing operations, it is convenient to run a nut on the thread as illustrated, so that the jaws will have a bearing to centre, and grip the work properly. This avoids all damage to the thread, and risk of the piece tilting and pulling over to one side.

The next example is shown at D. For those who wish to make a simple fine adjustment for their surface-gauge, the sketch C is shown. The method is to interpose a U-piece of steel between the base and the pillar, and so get a slight up and down movement for the final fine setting by springing this loop together or letting it open, the control being through the screw. The lower half of the loop is fixed by screwing it over a stud screwed into the base.

At E is a hint of an entirely different nature. This illustrates a simple device for bringing cylindrical pieces axially under the drill, so that the resulting hole will pass right through the centre. It consists of a small block of metal milled with a vertical vee-groove, to lie against various diameters of drills, and a transverse groove at the bottom to rest on the curve of the work, this permitting the latter to slide into correct relation to the drill.

The last hint is shown at F. It depicts a device for cross drilling in the vise. Readers are doubtless familiar with the tip of gripping a bit of plate on top of a shaft or spindle in the machine vise, the plate having a central hole to guide the drill axially across the shaft centre. A modification, which extends the usefulness of the idea, is to cut flats, on the plate as seen in the illustration, giving for example three different spans, to suit the vise opening on corresponding diameters of shafts.



THE VARIOUS IDEAS DEPICTED ARE REFERRED TO IN THE TEXT MATTER.

DEVELOPMENTS IN SHOP EQUIPMENT

ACKLAND SCREW DRIVER

The screw driver as depicted is the product of the Ackland Specialty Co., Springfield, Mass. It is said that this driver will remove any rusted or stuck screw which could not be budged by an ordinary driver.

The principle involved is an old established law of mechanics. A few pounds of pressure at the end of the upper bar and on the rachet handle results in a much greater pressure at the slot of the screw. This feature of course eliminates the danger of the driver slipping and ruining the screw slot.

HOW THE SCREWDRIVER IS USED.

Automatic and machine manufacturers are said to be especially interested. The blades are made from special heat-treated and tempered steel. The post is attached to the blade by a case hardened socket and sliding on the post is a rachet which permits using the driver in narrow and restricted places. The cross bar is secured to the post by a ball joint permitting movement in all directions.

The chain is attached on the end of the cross bar and looped around some projecting lug of the machine. A glance at the photo illustrates clearly the method of using.

PROFILE MILLING MACHINE

The Automatic Machine Company, Bridgeport, Conn., have placed on the market what is known as their automatic multiple-spindle profile milling machine. It is said to be specially adaptable for automobile engine work, or in other manufacturing where it is necessary to finish a large number of irregularly-shaped pieces.

A glance at the illustration will be worth while before going into further details. The spindle head can be made to accommodate any number of spindles, and their positions also can be arranged to suit the work. When a change is desired the spindle carrier is easily removed and a different one substituted, using the same spindles. These spindles are equipped with bronze thrust and taper bearings below, and straight bearings above, the central point where they are driven by spiral gears.

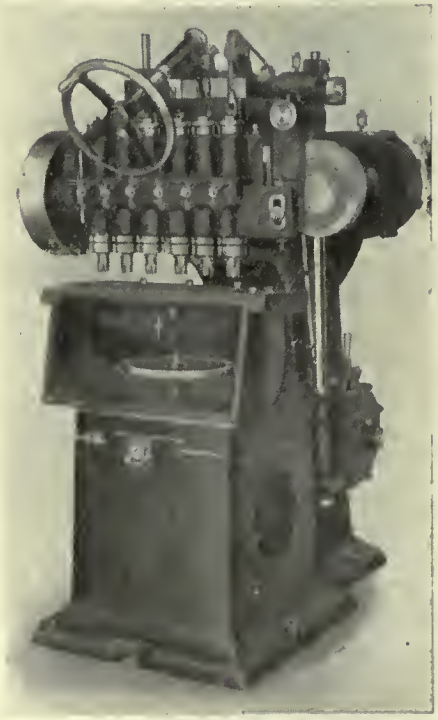
In operation, one cam moves the head or spindle carrier longitudinally and another moves the table or platen transversely. These are so designed and synchronized as to make the cutters follow the desired outline. After the cycle has been completed the feed trips out, while the cutters continue to revolve to clear themselves. The operator's duties are in this way confined to merely chucking and unchucking the work.

There is an adjustment for wear in cutter diameters in profiling any single design, and there is an additional adjustment on the traverse motion of the table to aid in setting the jig correctly and rapidly. The table is also provided with adjustable taper gibs.

An independent vertical adjustment for position of cutter on each spindle is provided, and the spindle bearings can all be adjusted for wear. The complete spindle head is counterweighted and is raised or lowered by the handwheel shown in the illustration.

The material and workmanship is claimed to be of the very best, and ball bearings are used to take the thrust on the spindle driving shaft, and the vertical worm shaft. Sight feed oilers are placed on the head and principal bearings, and accurate timing of the cams and gears is ensured by thorough running tests before shipment. Following are the principal specifications:

Number of spindles—as required. Table, 24 in. by 24 in. Height, from top of table to bottom of spindle, when up, 22 in. Longitudinal-transverse motion —to suit work. Dimensions over all, 4 ft. 6 in. wide, 5 ft. deep, 6 ft. 9 in. high.

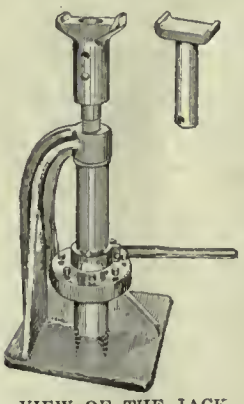


MILLER AS EQUIPPED WITH SIX HEADS

REPAIR JACK

The R. S. Whitney Manufacturing Co., Lewiston, Me., have placed on the market a safety repair jack which is illustrated herewith. This type of jack is designed to meet the demands of all classes of car, truck, and tractor repair work, and combines simplicity with strength.

All parts are properly proportioned, and a lever raises and lowers the screw, and is attached by means of a collar to the rotating nut. This, of course, increases the adaptability and flexibility of the jack. The rotating nut is placed at the extreme lower end of the screw in order to provide the greatest possible



VIEW OF THE JACK.

clearance. An extension supporting arm is also included, this portion being shown in the sketch. You can thus accomplish varied work with the one jack. The height closed is 19 inches, and it has a raising radius of 11 inches plus that of 7¼ inches, obtainable by using the extension arm, therefore the scope of usefulness and utility is practically unlimited.

FLUE AND PIPE BENDER

The Baird Pneumatic Tool Co., Kansas City, have placed on the market an arch flue and pipe bender as shown in the accompanying illustration. This machine is especially adapted for bending into difficult shapes locomotive or marine arch flues, also air pipe connections as used under the regular freight or passenger cars.

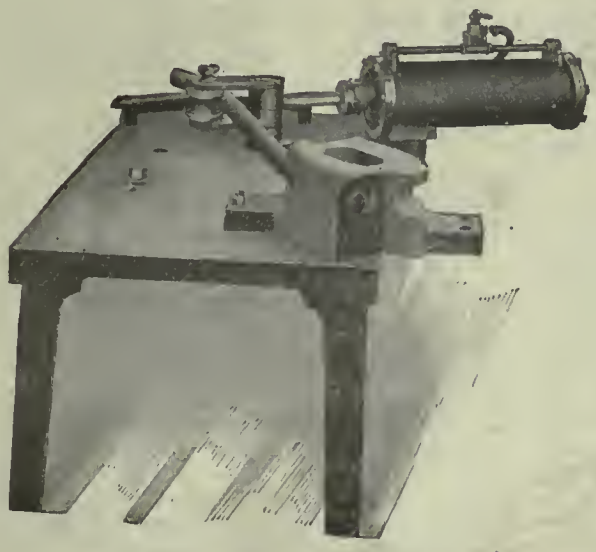
It is rigidly constructed to meet the hard usage of boiler shops, and will bend arch flues or pipe to any desired angle. It is not necessary to sand or heat the flues or pipes with this machine.

It is fitted with special blocks and forming rollers the exact contour of the outside diameter of 3 in. and 2½ in. boiler tubes. It is said that the round bend obtained by using this machine permits a flue-cleaning motor to pass through in the cleaning process. This is very often necessary in cleaning arch flues.

As can be noted from the illustration the complete machine includes cast iron table with planed, finished top. To this table is fastened the air cylinder supporting the piston directly connecting with the forming rollers and yoke, which in turn produce the radius bends in the pipe through the forming blocks and quadrant located at opposite ends of the table. This quadrant is fitted with a plug which can be placed in spaced stops to secure any radius within the capacity of the machine.

A patented four-way valve is fastened to the cylinder and within easy reach of the operator. Should more than the bend required be secured, by reversing the air valve the operator can take out the amount necessary. This notice should particularly interest railroad shops, marine plants, boiler shops, and shipyards. Following are the machine's principal specifications.

Diameter of air cylinder, 3 in.; stroke of piston, 26 in.; maximum travel of forming roller, 26 in.; air pressure required, 100 pounds per square inch; dimensions of forming table, 3 ft. by 5 ft.; bending blocks — one with capacities, pipe, ¾ in., 1¼ in., 1½ in., 2 in., 2½ in. and 3 in.



GENERAL VIEW OF THE BENDER.

NEW THINGS IN MACHINE TOOLS

UTILITY SCREW PRESS

A screw press that has been designed for a wide range of work has been placed on the market by Carl Pletz and Sons, of Cincinnati, Ohio. The machine is adapted for the straightening of shafts, bending bars or shapes, pressing in bushings, etc. The lower end of the steel screw is fitted with a special pad that remains stationary when in contact with the work, the thrust being taken on a bronze washer running in oil. When using a four foot bar it is claimed that a pressure of about 20 tons is applied to the screw. Two sizes are made, with distances under the screw pad of 14 and 20 inches. The approximate weight is 500 and 600 pounds respectively.

MILLING ATTACHMENT

A milling attachment that has been adapted for use on shaping machines, has been placed on the market by the Tri-State Milling Machine Company of Memphis, Tenn. The spindle is worm driven and is supported by a rigid overhanging arm, and the housing is intended to be secured to the ram slide, the ram being moved back out of the way. The table of the attachment is fastened to the table of the shaper with special provision for latter adjustment.

MULTIPLE-SPINDLE MILLING MACHINE

A multiple-spindle vertical milling machine has been added to the lines of the Betts Machine Company, of Rochester, New York. The machine is of rigid construction and is designed for heavy production work. The machine is made with three or more spindles as desired. The spindles are made from steel forgings driven through long splines and spur gears; spindles being adjusted vertically by hand. The machine may be belt or motor driven. Work holding fixtures are located on the continuous revolving table, the pieces being changed while the work is passing from one working position to the next. The table has a flat bearing on the bed and is driven through a large internal gear, all bearings being of bronze and all gears running in oil. It is claimed that one of these machines has a production capacity three times as great as a single spindle machine.

AUTOMATIC-STROKE BELT SANDER

A belt sander that automatically moves the sand belt across the surface being sanded has been brought out by the Mattison Machine Works, of Rockford, Ill. The machine is of rigid construction, the heavy casting carrying the power drive mechanism being mounted on two ample supports at either end. The shoe for applying the sand belt slides on a bar extending across the front of the machine, and is operated with a rapid reciprocating motion by a steel belt running over two flanged pulleys. Geared quadrants, which may be adjusted to suit any length of work, operate the pinions that drive the pulleys. All shoe connections are made of aluminum, and are counterbalanced. The work table is mounted on ball bearings.

FACE GRINDING MACHINE

The Diamond Machine Company of Providence, R.I., are now manufacturing an extra heavy duty face-grinding machine, that is intended for grinding operations on the heavier equipment that formerly has been accomplished on planing machines. The grinding wheel is made of the sectional type, a number of abrasive blocks secured in a chuck. Special attention has been given to the handling of the coolant, so that clean, cool liquid is returned to the circulating system. Duplicate control is provided so that the machine may be operated from either side. The machine is motor driven through a Morse silent chain.

Paying the Real Increase

AN Ottawa despatch credits Hon. F. B. Carvell, head of the railway commission, with a statement to the effect that the increase in freight rates could not possibly amount to more than 15 cents per ton of coal coming to Ottawa. This figure came out because it was reported that certain coal dealers were to raise the price of coal 50 cents per ton on the head of the new freight schedule.

Right here is where the big complaint is constantly raised. Wholesalers and retailers alike complain that by the time increased freight charges are passed on to the customer they amount to three or four times the amount granted to the carrying interests.

The statement of Hon. Mr. Carvell that 15 cents is the increased cost of a ton of coal in Ottawa suggests that it might be well for the railway commissioners to have worked out a table showing the exact increases on a given list of staples in the principal points in Canada.

By so doing they would be giving the public the protection to which they are certainly entitled, and the absence of which is liable to leave openings for increased prices that have no foundation in fact or reason.

It is true that many papers are publishing figures showing how the rates affect certain lines, but these are not accepted as official, and they lack, for that reason, the weight an official ruling would have. For instance, were it handed out by Ottawa, in an official way, that the increased carrying charges on a ton of steel from Pittsburgh to Toronto, or Montreal, having regard to the added increase in the cost of moving the raw materials in the first place, amounted to one or two dollars, or whatever the figures actually were, the trade would accept that ruling and adjust schedules accordingly.

The trade generally, as far as lines covered by this paper are concerned, believe that if the freight service is improved forty per cent., along with the forty per cent. increase in rates, it will have been a fairly good investment. They know that industries are having a hard time in many cases because they cannot get the service they require from the roads, and they know that many firms have been put to a lot of expense in having to provide their own carrying service. On the other hand, if they put up the increase of forty per cent. and do not receive a better service it will simply be that much money passed over to the roads.

Mechanical Drawing Is Not Fancy Work

MECHANICAL drawing at Toronto Exhibition seems to appeal to the directors as worthy of a place in a building devoted to needle-work, etc.

The fancy work is placed first, and the room that is left at the top of the cases is devoted to a display of mechanical drawing. Then, a few pieces being left over they are hung upstairs to the accompaniment of more lace and photographs.

Mechanical drawing is a part, and a very important part, of the machinery field, and cannot be alienated from it.

It is not fancy work—neither is it a pastime. It is serious, constructive and essential work and the people who would be most interested in it, and who would profit most by it, are the men who visit Machinery Hall.

It might be possible also to introduce something in the way of designing, rather than in copy work, bringing perhaps from twenty young minds an idea or two that might be of the real worth-while type.

The Double Steel Market

RIGHTLY or wrongly, there is a growing feeling in the steel trade that there will be a levelling process soon that will do away with the two-headed market that has existed for some time. By a two-headed market we mean the selling price of the corporation as opposed to the selling price of the independents.

It may be that the corporation figures will come up a little, while it can be only a matter of time before some of the prices now secured by the independents will have to sag, although there are some of them brave enough even yet to talk about the prices increasing.

Right now Canadian warehouses are buying sheets in United States, for which they are paying nine cents a pound in New York funds. The average price for these covering some years is shown in the following table, prepared from the current market quotations at Pittsburgh:

1905	2.28	1913	2.20
1906	2.47	1914	1.89
1907	2.60	1915	1.93
1908	2.48	1916	3.06
1909	2.26	1917	6.29
1910	2.29	1918	4.98
1911	2.03	1919	4.43
1912	2.00		

An explanatory note in the Pittsburgh market records states that the prices in 1919 are subject to certain premiums for quick delivery.

Those who must have material are buying and paying for it, but the present price schedule does not encourage buying for stock, thus giving the volume of orders that the mills must sooner or later have to operate at capacity and at low cost.

The pith of such plants as the sunflower, rush or elder is advocated by the "Scientific American" as a good material for cleaning the lenses of scientific instruments.

An extension of the Temiskaming and Northern Ontario Railway from the present terminus at Cochrane to James Bay is shortly to be undertaken by the Ontario Government.

MARKET DEVELOPMENTS

A Readjustment of Steel Prices Likely

Report Gains That Corporation May Come Up While Independents Ease Off—Freight Rates Should Result in Better Service—Railroads Are in Market for Some Equipment.

WHERE and how the new railway rates will fall is one of the topics that the market discusses at length this week. In some cases it will make no difference in prices quoted, although the difference will come when the buyer pays for the haul from the present location of the material to his own premises. Much material in the steel trade has already felt the total cost of haulage increases because the U. S. freight rates cover the case. Considerable of the concern is that the purchaser shall pay only the increase granted to the roads.

Although there is nothing official to warrant the belief, the trade seems to feel that there is bound to be a move that will do away with the dual steel market that exists now, viz., the selling schedule of the corporation and of the independents, between which there is a difference so great that it cannot be reconciled. Most of the deliveries that are finding their way into this territory now are coming from the independent mills, and as a result the prevailing prices are very high.

Machinery houses report in several cases that they have had a number of very interesting inquiries during the past few days, and that deliveries on orders that have been booked some time ago are coming through in a very satisfactory way.

The Government railroads are buying small tools now, particularly carbon and high speed drills. As a general thing though the trading that is being done is in smaller lots.

Several houses report that they find it necessary to pay more attention to their collections than usual, reporting some of these as being rather slow.

In hardly any section of the steel, iron or allied trades can it be said that there is any buying being done for stock now, prices and deliveries being very much opposed to any such policy.

MONTREAL TRADE NOT WORRIED OVER THE INCREASE IN FREIGHT

Special to CANADIAN MACHINERY.

MONTREAL, September 16.—Business and industrial conditions are developing a gradual improvement as the mid-summer holiday season comes to a close. Some factories that have been curtailing operations, due to a shortage of fuel, are more actively engaged, and in many lines the prospects for a busy fall season are quite marked. Following the announcement of the increase in freight rates the Railway Board have received many requests for deferred action, but while recognizing the right to appeal, the Board authorizes the increase to become effective at once. In the statement issued, the following clause is inserted: "If it should appear to be a case where the appeal should be granted and the decision modified or reversed, there could, if deemed proper, be provision for rebates of rates charged beyond those ultimately fixed."

Better Delivery Offsets Freight Increase

It is expected that the 40 per cent. increase in freight rates will ultimately mean that steel commodities will be advanced in price sufficiently to meet this additional charge. Where the steel is taken from warehouse stock the price that has been effective is still quoted, but where material is shipped from the mill the added freight charges approximating 17 to 20 cents per hundred pounds, are included in the invoice. This condition will apply generally when local supplies are exhausted. The car situation in this district is quite normal but congestion in the vicinity of American mill point prevents the regular shipment of steel, and dealers and consumers in distant sections are frequently inconvenienced by the non-delivery of much needed material. The demand for steel lines has shown no marked improvement, but the movement is steady and of an encouraging character. The situation may be summed up in the statement of a dealer here when he said: "Users of steel are not buying any more than they need but are willing to pay for what they want." This would appear to indicate that buying is not restricted for urgent requirements, but that only immediate necessities are given consideration. The supply of sheets is still below the maximum trade requirements, but owing to the failing demand from the automobile industry the quantity of available sizes is showing improvement, and it is not improbable that the market conditions may offset the increased cost of transportation, and as a result the quotations on some lines may not show the added costs of haulage.

Present Activity Slight

"The increased freight charges will have little material effect upon our business, as present operations are on a restricted scale owing to the continued dullness of the market. Movement is almost confined to local activities and little railroad transportation figures in its shipment, but where material is required to be placed on the railroads for distant haulage the customer naturally or automatically pays the extra charge." This statement shows the quiet state of the old material situation, and in some respects the dealers are disinterested in the present market. There is, however, a feeling that the railroads will make every effort to establish normal conditions before the winter actually sets in, and if this can be effected there is a large possibility that improved operation would follow in many lines of industry and open the way for a better demand for a greater range of scrap materials. Last week's quotation may be considered as nominal with an upward tendency.

WANT TO GET A BETTER SERVICE

Believe Rates on Railway Will be Worth While if it Results in Quicker Shipments

TORONTO.—The market is adjusting itself this week to the new freight charges. It was only a couple of weeks ago that the new rates from U.S. points were taken care of, and in doing this a revision of rates on account of Canadian changes has been made unnecessary, as much of the shipments come from points in United States.

While there is in some concerns an alarm at the principle of continually increasing costs, there is no alarm over the new rates as a general thing. Here are a couple of opinions, one of them from a leading warehouse, and another from the manager of one of the largest selling forces for machine tools and other lines.

"As far as the business of the steel yards is concerned, we believe the rates are all right. Much of the material we get is from Pittsburgh, and the rates we have announced, amounting to an increase of $2 per ton in most lines. cover all the increases that are necessary. One of the worst things that the manufacturers with whom we have business in Canada have to contend with is the fact that railway service has been very indifferent for many months past. There are plants that have had to resort to all sorts of schemes in order to give service to themselves that they should get from the railways. If the increase in rates will enable the roads to get their equipment whipped into better shape, then we believe it will be a good investment to pay the increased carrying charges."

The manager of the other business spoke along similar lines. "I can show you a good many lines where our increases have been over 40 per cent., which is the amount now allowed the roads. The whole thing hangs on the performance the roads are prepared to give for the increase granted them. If there is no improvement over what we have been experiencing, then we will look upon it as just that much needlessly added to the cost of carrying on business, which we have to pass on to the men who buy from us, but if we get a 40 per cent. improvement in the service from the roads. then good and well, we will have something for our money, and it will be a good investment."

Must Watch Closely

Others point out that it is necessary for dealers and manufacturers to watch very closely all the increased charges that have been put into effect, and see that they are not trying to absorb too many of them, and by so doing wearing down their margin of profit, past which it is not safe for them to go.

In this same connection, the market reports that more attention is being paid to collections as a general thing than for some time past. Some dealers report that they are having more trouble now in keeping their books well cleared up, and firms that before always paid promptly, are now taking advantage of every circumstance to extend their payments over as long a period as possible.

POINTS IN WEEK'S MARKETING NOTES

August production rate of iron and steel was the largest since December, 1918, barring last February and March.

—

Pittsburgh claims a decided improvement in freight movement, saying that in many lines the business is nearly normal.

—

There are few new buyers in the steel market and business is dull as far as new bookings are concerned.

—

August shipments of steel are stated to be about 90 per cent. of the output.

—

The Government railroads are in the market for carbon and high speed carbon drills.

—

The steel trade feels that if higher freight rates can bring about a more efficient service it will be money well spent.

—

There is not the insistent demand for plate there was a few months ago, and dealers claim there is enough in the yards to care for all the business that is offering.

—

A shortage of cement is holding up work on the Welland canal. The contractors claim the large shipments going to United States are responsible for this.

—

Shipments of machine tools are very satisfactory now. Some firms think September will be one of the largest delivery months of the year.

—

Warehouse prices on bar iron and steel, plate, sheets, etc., were put up $2 per ton.

—

All soft steel bar makers are practically sold up for the remainder of the year.

—

Some rail tonnages of importance for 1921 delivery have been accepted by mills, but the price is left open till Jan. 1.

—

English makers of ferromanganese have cut their price to this country $20 per ton.

—

Lack of old rails is apparently all that is holding up large trading in hard bars, one interest reports having to turn down inquiries aggregating nearly 10,000 tons for this reason.

The Steel Market

The opinion is expressed, although there is nothing in fact to back it up, that the U. S. Steel Corporation prices will be raised and the prices of some of the premium mills will be lowered. "For a long time," stated one manager this morning, "there have been two separate and distinct markets, a high one and a low one, but unfortunately there has been only one seller, and that is the premium operator. We have had business booked with the Corporation for months, and we can't get an answer as to when it is coming through. But the continued existence of two steel markets is too absurd to last long."

There has been a fairly heavy shipment of tubes, and they are much needed. Most of them are 16 ft. 3¾ in., and many of the larger power plants are persistently in the market for these and the four inch tubes. A fairly large tonnage of two inch tubes is coming through, these being used more for smaller plants, for locomotives, etc.

There is nothing like the demand for plate that existed some months back, and of this line it can be said that there is not much trouble now in getting all that is required for ordinary purposes.

The sheet users are all in trouble together, and no one seems to be any worse off than his neighbor. Sheets are coming through in a week to ten days, from some of the independents, the price for black 28 gauge being 12.10 per lb.

The Machinery Market

A fairly good business is being done in machine tools, some places having disposed of a good assortment of these during the past few weeks. There is an improvement in the number of inquiries coming into the market, and dealers are hopeful that there will be a decided improvement later on.

The railroads—National—have specifications out for a fairly good list of carbon and high speed drills for some of the eastern shops, but otherwise the buying is being done by smaller interests. The automobile interests are not taking on anything like the stock they were a few months ago, and no large buyer has come in to take up the sag.

The scrap metal business is having a short week, because nearly all the yards are closed owing to the Hebrew holiday season following their new year celebrations. Trade during the past few days has shown no improvement over what has been experienced. Few buyers are in the markets for material, and the yards are buying very closely in what they do take on.

DIAMOND
DISC GRINDERS

Good grinding in fast time has made the Diamond popular in a host of shops. The right design and build eliminate vibration and give the operator a perfect surface every time. There is a suitable size and equipment for every surface grinding job you have. Workmanship and material of "Diamond" quality throughout.

SHIPMENTS IN AUGUST WERE 90 PER CENT. OF STEEL PRODUCTION

Special to CANADIAN MACHINERY.

PITTSBURGH, Sept. 16.—The iron and steel market continues stagnant in practically all branches. It is a case of the trade going ahead on its momentum, as producers are well filled with business and production is fully absorbed by deliveries against orders already in hand. Consumers desire to be obligated only to take such material as is required for business they have in hand, and as deliveries are better there is less demand for prompt lots to piece out with contracts.

Heavier Steel Production

The monthly report of the American Iron and Steel Association shows 3,000,432 gross tons of steel ingots produced by the 30 companies that make monthly reports, against 2,802,818 tons reported for July. Computing on the basis of the number of working days in the month and year, and allowing for the unreported production, ingots were produced during August at the rate of about 42,700,000 tons per annum, showing a 7.0 per cent. gain over the rate in July. This is a large gain from one month to the next, and is particularly striking in view of the fact that August, being a midsummer month, would be subject to the same adverse weather conditions as July. Barring last February and March, the August production rate is the highest since December, 1918.

Shipments Heavier

In August there was a double gain in shipments, since the production was larger and the mills shipped more than their production, instead of shipping less as they had done in July and in the three months preceding. During those four months they had to stock some of their output, on account of car shortage. About the end of July the turn came, shipments and production being approximately equal. Since then shipping conditions have constantly improved. As to the total volume of freight movement, the last week reported upon, that for the week ended August 14, shows the largest number (962,352) loaded for that week in any year, the number just passing that in the record year, 1918. An authority estimates that by this time the total freight movement is not only ahead of that in the same period in any year, but is ahead of the best record made in any week in any year. As to steel shipments, they were naturally very heavy when production was at the rate indicated and shipments were in excess of production.

Of the finished steel products accumulated during the car shortage easily the major part has now been moved. There remains considerable tonnage of semi-finished steel, the steel having been put in that form as a convenience, with the idea that it could gradually be fed to finishing mills as supplementary to the current production of steel. The finishing departments can, of course, stand only a slight overload, and thus with the best shipping and market conditions it would be quite a while before all the semi-finished steel could be worked off.

Momentum of the Trade

It has been made clear to everyone that the pig iron and steel markets have gotten into a condition of dullness from which they will only be resuscitated by a marked improvement in general business conditions. There is nothing in the markets themselves that would lead to there being a fresh buying movement. The influence must come from without, as buyers are now to be supplied with heavier deliveries than they were getting, on an average, in the past five months, so that the requirements of buyers must increase before they take much interest in making fresh commitments.

In the circumstances, the only question is how long the industry will be able to keep busy on its present commitments, or in other words how long the momentum will carry the trade. At a juncture like this there is always a difference of opinion. Some observers point to "full order books" and compute how long the orders will last the producers. Others assert that order books count for nothing, that orders can be canceled and buyers order shipments suspended or curtailed. Experience gathered over many years, from various situations like the present, indicate that neither party is exactly right, but that the former come nearer being right. There are always cancellations at a time like this, and there have been this time, but the cancellations amount altogether to but a very few per cent. of the total amount of business on books. Quite possibly a great deal of business would be canceled if the market broke, but the producers always look out for this. When the time comes that they see little new business to be secured either at existing prices or even at deep cuts, while a great deal of business is to be squeezed out of existing contracts, they simply "stand pat" on their prices. To cut prices, to engage in competition, would be simply for the mills to swap orders with each other at lower prices all around.

Accordingly there is the experience of mills in general adhering stiffly to their previous quotations, with the exception in some cases of such small mills as have been securing the outside prices on account of being able to make very early deliveries. When such mills reduce prices they are still above the general average of the independents. The Steel Corporation is in a class by itself, its prices being so much lower than the lowest of the independents.

Steel Corporation Tonnage

For the first time since May, 1919, the United States Steel Corporation has shown a decrease in its unfilled obligations, the last report showing 10,805,038 tons of unfilled business at the close of August, this indicating a decrease of 313,430 tons in August, comparing with an increase of 139,651 tons in July. Thus there was a change of about 450,000 tons from one month to the next. About half of this was due to an increase in shipments and about half to a decrease in bookings, or rather in the net bookings, as there may have been some cancellations in August, offsetting a small part of the bookings. Shipments in July may be estimated at 75 per cent. of capacity, and August shipments at 90 per cent. As the August decrease in unfilled obligations was about 23 per cent. of capacity the net bookings in August were about 67 per cent. of capacity. The unfilled obligations left are equal to about nine months of production at say 90 per cent. Should the corporation book month by month only one-half as much as it shipped, this being a very low estimate, the orders, if properly distributed to the different departments, would theoretically carry the corporation for 18 months instead of nine months.

Pig Iron

Production of pig iron increased in August as compared with July and the increase in merchant output was particularly sharp, being 6.7 per cent. The August rate of output was barely a shade under the rate last March, and otherwise was easily the heaviest rate shown by the merchant furnaces in a year and a half. This puts somewhat of a new aspect on the price advance that most pig iron producing districts brought about late in August. It is notable, now, that the Chicago district furnaces refrained from advancing their prices. They are still on the basis of $46 for No. 2 foundry iron, while the valley and Cleveland furnaces are at $50, and the eastern Pennsylvania and Buffalo furnaces are still higher. More important still is the refusal of the southern producers to put up their prices. They are still at the $42, Birmingham, figure attained at the end of last April. The furnaces could undoubtedly have advanced prices above $42 if they had desired, but they considered it wise not to do so. There is now a deadlock in the pig iron market, and one should experience no difficulty in deciding which party is going to yield first. Nothing may occur, however, for several months, as the present engagements will last both parties quite a while.

AIKENHEAD'S

CANADA'S LEADING TOOL SUPPLY HOUSE

Aikenhead's

International Electric Glue Heaters

Built in a variety of sizes to operate on dry heat and having temperature controls giving three distinct degrees of heat—full, medium and low, the International Electric Glue Heater meets the requirements of all shops large and small.

The International reduces the cost of maintaining glue at the correct temperature to a minimum, the 1-quart heater consuming only one cent's worth of current per day, while the larger sizes show even greater relative efficiency.

Uniform temperature is easily maintained at all times and under all conditions, a feature which will be appreciated by all practical glue men.

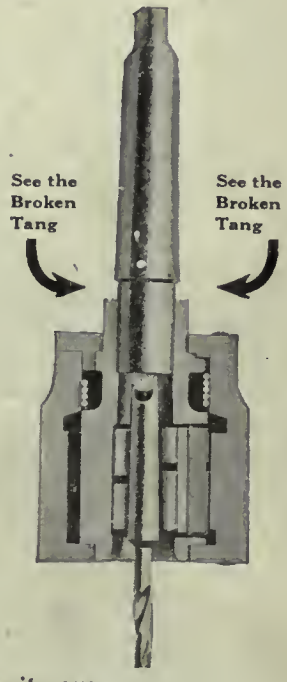
Every "International" Glue Heater is fully guaranteed to give satisfaction in the service for which it is intended.

Prices and full information on request

Buy Them At Aikenhead's

The Wahlstrom Automatic Drill Chuck

Good Tangs or Broken Tangs, It Matters Not With a Wahlstrom



Do you salvage or discard your broken tang tools? Repairing or replacing them is unnecessary, for **Wahlstrom Automatic Drill Chucks** will hold tools whether they have tangs or not—the jaws grip on the sides of the shank—not by the tangs.

The percentage of reduction in your tool upkeep cost is governed entirely by the number of **Wahlstrom Chucks** operating in your plant. They pay for themselves.

There's no time lost in waste motion with the Wahlstrom Chuck. It is automatic and instantaneous in action. It enables the operator to make **tool changes in just two seconds,** without stopping the spindle of the machine.

In addition to regular drill press work they will increase production of lathes for burring, turning, filing, etc.

Made in two different styles. One style holds No. 1, 2 or 3 Morse Taper Shank Drills —with or without a tang. The other style is made in three sizes, which hold all sizes of straight shank tools from ¼ to 1-inch.

Give your men this keyless and colletless chuck. Results will prove it pays. Sent on trial.

AIKENHEAD HARDWARE LIMITED

CANADIAN QUERY IN U.S. MARKET

Railway Specifications Are Being Look-Over—Business is Not Brisk

Special to CANADIAN MACHINERY.

NEW YORK, September 16—Several New York machinery dealers are quoting on the recent inquiries of the Grand Trunk Railway System (George W. Caye, purchasing agent, Montreal, Que), which call for both metalworking and woodworking tools for various Grand Trunk shops in Canada. Among the machines called for are the following: Two driving wheel lathes, 90 in. swing; two gap lathes, Bertram or equivalent; one 60 in. duplex horizontal driving box boring machine; one universal horizontal boring machine, equivalent to No. 32 Lucas; two single frame steam hammers, 800 pound; engine lathe, 26 in x 12 ft.; crank shaper, 20 x 22 in.; Fox turret lathe; radius link-grinding machine; Gisholt horizontal axle-box boring machine; McCabe pneumatic flanging machine; 35-ton hydraulic spring-testing machine; six Bridgeport grinders; 42 in. car wheel lathe; triple head bolt cutter; four sliding head Sibley drill presses; 26 in. woodworking tools as follows: one double arbor universal saw bench, one 36 in. band saw, one 16 in. hand jointer, five swing cut-off saws, one combined radial car boring machine, four self-feeding rip saws, four vertical hollow chisel car mortisers and borers.

The American Brake Shoe & Foundry Co., New York, is asking for bids on about ten machines. Other inquiries are few. Eastern railroads are not doing any buying of consequence, but there is a fair amount of buying in Chicago, principally by the Chicago & Northwestern and the Santa Fe roads.

Machine tool business has suffered a severe set-back in the past six weeks or two months, and the effects of this are seen in the slowing down of manufacturing operations at some machine-tool plants and the catching up on deliveries, some machines now being available out of stock. Prices, however, show no apparent weakness; in fact there have been some advances recently. The outlook for the future is somewhat uncertain; there are some in the trade who do not look for any pronounced revival in business before spring, while others think that a renewed demand will develop much sooner, possibly after the presidential election in November.

The full-rigged three-masted sailing vessel, Grand Duchess Maria Nikolawna, now in the harbor of Montreal, presents a striking contrast to the modern present-day steel freighter. This ship has a registered tonnage well below 2,000, but carries masts of such a height that it was necessary to step her main-topgallant mast in order that she pass beneath the Quebec bridge. The vessel was originally built in 1873 by R. Steele & Co., of Greenock, Scotland, and on her recent voyage out from Newcastle-on-Tyne made the trip in thirty days.

SIGNS OF PROGRESS

Imperial Oil is to build a $250,000 distributing plant at Brandon.

Dominion Bank is building a three-story premises at Brantford.

Masonic Hall at Bridgeburg is planned to cost $20,000.

Imperial Steel and Wire Co. are to start on new buildings at Collingwood.

Fisher Body Corp. is to build a factory at Ford City to cost $175,000.

Dominion Oxygen Co., Ltd., may build a factory at Halifax.

Steel Co. of Canada, will build a storage warehouse on Harvey Lane.

Taylor and Campbell are building an electrical factory on Adelaide Street, London.

Bank of Nova Scotia is building at Moncton, N.B. Dominion Bridge Co. have contract for the steel.

Willard Automobile Storage Battery Co., Cleveland, plan half million plant in Toronto.

Canada Bread Co., Toronto, build brick and steel stables and factory in Toronto, at Danforth and Ladysmith.

The Engineering Sales and Service Co., 55 St. Francis Xavier Street, Montreal, have obtained the Canadian agency for Haughton's Patent Metallic Packing Company of London, Eng., manufacturers of high grade anti-friction packings.

The C. P. H. Gas Engine Company of Canada, Ltd., with offices in the Dandurand Building, Montreal, expect to build a plant for the manufacture of a new type of internal combustion engine which is particularly adapted for all classes of service. J. Van der Ghote is secretary treasurer and general manager.

SHOP SECRETS ARE PROTECTED

Justice Guerin has handed down, in the Superior Court, an important decision on the question of the ethical and conventional obligations between employees and employer in condemning Siegfrid Sanders to pay $100 damages and the costs of an action brought against him by the firm with whom he was formerly employed in this city. The company maintained that Sanders, in the course of his work, acquired in confidence knowledge and information respecting the making and methods of a special machine, and that after he left their services he revealed this information to his new employers. His former employers allege that they sustained a severe monetary loss.

The company further alleged that Sanders had been employed by them to devote his time exclusively to their manufacturing department, and they also alleged that he agreed not to "directly or indirectly" make known to any persons, either during the period of his employment or thereafter, any of the special processes or knowledge of special machinery which he might learn from the company during his employment.

YARDS HERE TO FINISH THE BOATS

Ottawa Makes That Promise and Winter Work at the Yards Will be Assured

Herbert Wright, business agent of Toronto Local 128, International Brotherhood of Boiler Makers and Iron Shipbuilders, whose members are out of employment through the failure of the Dominion Shipbuilding Company, announced, following his return from Ottawa, that ships which the company was building for the Government would be proceeded with. Osler Wade, assignee of the company, had refused to continue the contracts, since he feared that they would be built at a loss.

"I saw Senator Robertson, Minister of Labor, and he assured me that the Government would proceed with the ships this fall. I don't know exactly when the work will commence, but I believe that it will be when the present vessel is finished," said Mr. Wright. "There was nothing said during the interview regarding labor conditions, which were given as one cause which contributed to the failure of the company. He did not mention it, and I presume the same rate of wages will be paid."

To Build Tankers.—According to Mr. G. A. Reading, representative of Robt. Reford Co., steamship agents, the keel of a ten-thousand-ton oil tanker will, in a few weeks, be laid on the ways recently vacated by the "Canadian Mariner," at Halifax. If all goes well the Halifax shipyards will contract for the construction of several oil tankers of large tonnage. Mr. Reading added: "The recent launching of the Canadian Mariner marked the fulfillment of the dreams of shipbuilding officials in Nova Scotia. Built entirely of steel by Canadian workmen, it is the largest ship ever launched in the province." As this was the first ship to be built by the Halifax shipyards the launching was naturally viewed with some trepidation by the promoters, and it was with relief that they saw the big vessel slide easily from her stocks.

J. B. McAndrew, of St. Catharines, Ont., has been appointed by the Civil Service Commission, Ottawa, to the position of Structural Engineer on the Welland Ship Canal.

W. F. V. Atkinson, consulting engineer and formerly chief forester of the Spanish River Pulp and Paper Mills, Ltd., Sault Ste Marie, Ont., has moved to Toronto, where he will continue in private practice.

H. Dixon, formerly chief engineer of the Canadian Northern Railway, has been appointed chief engineer of both the C.N.R. and the G.T.P., following the amalgamation of the two lines. Mr. Dixon's headquarters will be in Winnipeg.

Belting as a Means of Power Transmission

In a Previous Article We Dealt with the Chain as a Medium, But in This Present Case We Speak of the Uses of Belting and How to Care for It.

By J. H. MOORE.

READERS will no doubt recall an article dealing with chain drives, which appeared in a previous issue. In the present article we will take up the other extreme, namely that of transmission by means of belting. It is of course understood as before that we are not advocating any particular style of drive, but are merely presenting for readers' benefit the two sides of the case.

When we speak of a belt drive we can infer anything from the 1 in. single-ply belt up to the larger and heavier class of belting as used for extreme heavy service. We might not necessarily refer to leather belting alone, for there are many fabric belts of various natures being used at the present time. Each manufacturer has his own particular claims regarding the merits of his own product, and as we have no intention of entering into a controversy on this subject we suggest to readers, who desire comparison, that they study at all times the advertisements as appearing in this and other technical journals. Manufacturers in general are only too pleased to tell you about their wares in such advertisements, and a study of the same will prove worth while.

The point we wish to emphasize is not so much what each type of belt will accomplish but rather where belts can be used and what care they require.

Take a tour through any manufacturing plant to-day and what do you find? Line after line of shafting on which are pulleys almost innumerable. Over each pulley we notice a belt leading to still another pulley, this latter one being on either a countershaft or on the machine which is being driven. If the former case holds true, we see yet another belt leading from the countershaft to the machine, and so it goes on. Trace the source of power from the motor to the line shaft and we generally find that even the motor has a belt leading from its pulley to the driving pulley on the line shaft.

In other words it is a case of belts, and then more belts. In some instances you will find the machine tools driven by individual motors, but even in such cases a belt is often used to transmit the motion from the line, or motor shaft itself, to the other portions of the machine. To state everywhere that belts can be used is an utter impossibility, for we would be sure to miss something or other, but generally speaking we have the manufacturing plant, the machine shop, the power house, agricultural machinery, and in fact every source of revolving motion can make use of belts of some kind.

The Belt to Use

To find the type of belt best adapted for a particular drive is not always an easy problem as many demands are made on belts, these demands differing under various conditions. In some cases weight of material is the big requirement. For instance, belts used for compressors and hammers require good weight. Then there is the belt used on a grinder. Such a belt should run absolutely true and have no side play.

So it goes on, each problem entirely different. No one type of belt is good for all conditions, so that it is up to the user to watch how his various belts stand the grind. When you find one that gives you real service, stick to that type and do not go around experimenting with some inferior belting which may cost a little less but cause unending trouble. The cost of a belt is only one item in the programme, and a very small item at that. Of course there are cases where you can make a change for the better, but be sure it is for the best. This may sound contradictory after saying do not experiment, but what we imply is this, never purchase a large quantity of untried belting at one time. If you hear of a belting that you believe would be better for your purpose, secure enough for one machine only. Run a trial run on this new belt, making it undergo a real test, studying the result.

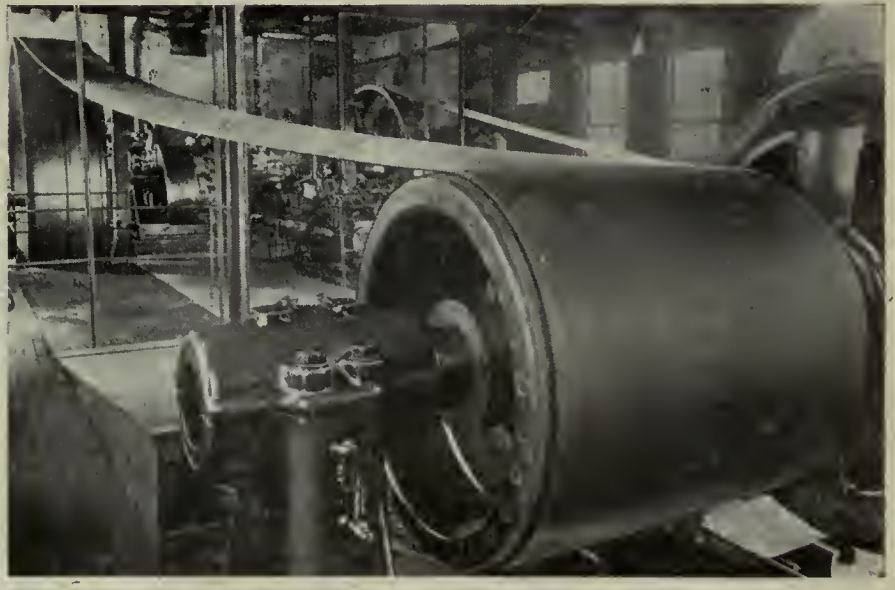

FIG. 1—A 34" BELT ON A GENERATOR DRIVE.

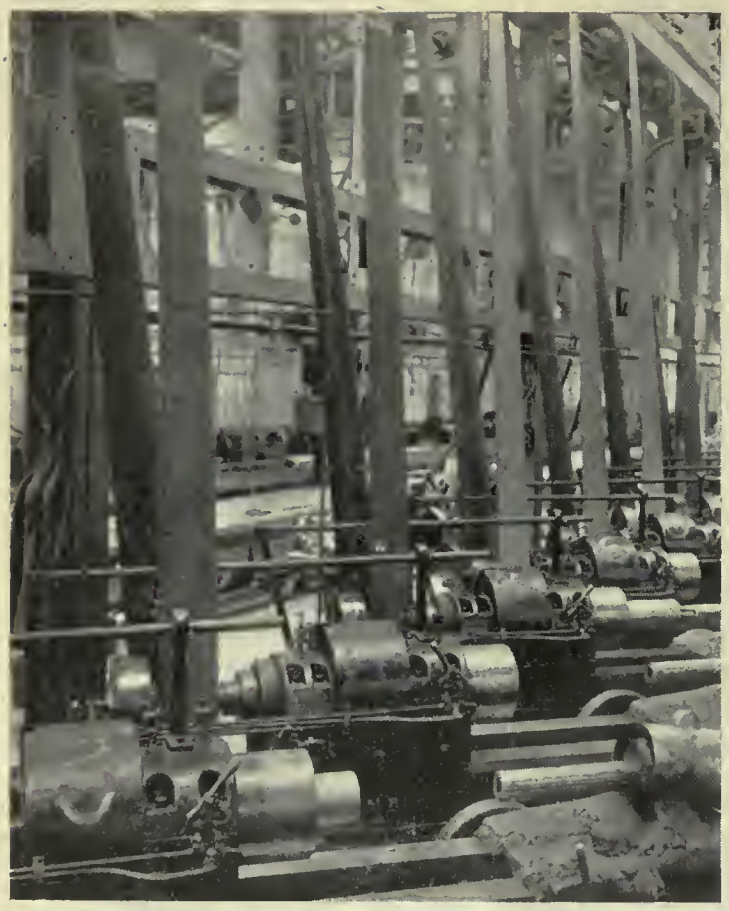

FIG. 3—A NEAT BELTING ARRANGEMENT.

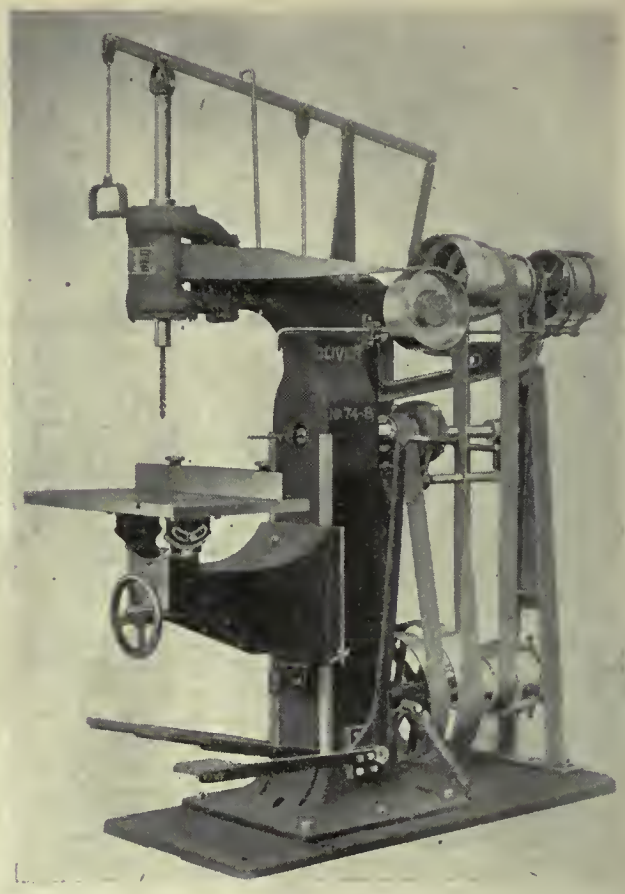

FIG. 4—A GOOD ARRANGEMENT OF BELTING.

You are then able to form a true opinion as to its merits.

Points to Watch

If testing a belt be sure you give it a fair trial. You can ruin a belt's chances in various ways. For instance, don't expect any Tom, Dick, or Harry to place your belts on the machines. Have a man for that purpose who knows enough to make his belt joints properly and so on. Metal fasteners put in crooked, holes too large, in the case of belt lacing, rivets put in any old way, if belt is riveted, etc. These are just a few things that one must not do if a belt is to be given a fair trial. Another point to watch is that of roof clearance.

In many cases the roof of factories consists of beams or joists, these having to be cut away slightly to give the belt clearance. The average worker seems to be afraid to weaken the roof or something, for he cuts barely enough to allow the belt to pass. The result is that if the load on the belt fluctuates at all the belt flops up and down, this action naturally decreasing its life to a considerable extent, especially at the joint. This point of proper clearance is one that should be carefully watched. Crowned pulleys are a great help to the smooth action of a belt, and luckily manufacturers in general are realizing this point more than ever before.

Quantities of Belt Used

To illustrate clearly that this discussion is not one-sided, we will boldly state that very often more belt is used than is absolutely necessary. For example, heavy machinery should, whenever possible, be arranged near the main drive so as to economize both in the length of heavy shafting carried and in the length of belting used. Where machines do not run continuously these should be grouped together, as continual starting and stopping involves considerable wear and tear on any belting. We have viewed many a case where a machine has been planted down with no thought of ideal position, with the result that not only more belt was used than required, but loss of power resulted.

Another cause of wear and tear on belts is that of improperly aligned shafting. Poorly laid out shafting means wobbly pulleys, these in turn adding to the already existing strain on the belt.

Care for Your Belts

And now a word regarding the care of belting. The life of any belt depends upon the good judgment with which the belt is selected for its work and the care which it receives. Take for example a leather belt. It requires very little attention in service, but nevertheless it requires some. It should be kept clean, and if the ends are not lapped the lacing or whatever connection is used should be kept in order, so that the ends of the belt may be held perfectly square with each other.

Whenever possible a belt should be made endless on the pulley. A new endless belt will of course require to be tightened after being used a short time, but this is a small matter, and after this has been done the belt will run for a long time with no other attention except occasional cleaning and dressing. Should there be lacings or hooks which have injured the ends of a belt, new pieces may be cemented on them. If possible never have more than one joint to a belt. A wide belt is often cut in half, longitudinally, and used as two belts for smaller width pulleys. This is practical where one cannot procure the width they desire, but it is good practice to stick to standard widths of belt wherever possible.

Belt Dressing

To increase the pull of a leather belt the use of belt dressing is often resorted to. When judiciously applied this is a good idea, but where careless or thoughless application is made, the result is detrimental and is very destructive to the belt. First, before placing belt dressing on any belt be sure of the belt dressing. Be positive that there is nothing injurious to the leather in the dressing. As we are all aware, the driving power of a belt depends upon its flexibilty and adhesive properties. The object of a dressing therefore must be such as to retain these essential qualities. The adhesive action can be increased by careful application of a guaranteed dressing, but it takes a liquid or semi-liquid preparation to penetrate the

pores of a belt, thus giving it pliability. Never use a dressing to maintain the pull on a belt. As an aid it is ideal, but at the first opportunity take up the unnecessary slack.

Should you use too much dressing the pulleys will get all gummy, large patches of dressing sticking up on the periphery. This forms air pockets, so to speak, between the belt and these patches, thus decreasing instead of increasing the driving power.

Never allow such a condition to exist. If necessary knock off the belt, scrape both the pulley and the belt, and start afresh. In other words, if you must use dressing, use it wisely, not lavishly.

Examples of Belt Drives

Fig. 1 depicts an interesting belt drive at the Morristown Water and Electric Light Co., Morristown, Tenn. This illustrates a 34 in. Heart double belt on a generator drive. Note the smooth action of the belt, and as this cut is from an untouched photograph it still more emphasizes the fact of the belt's smooth motion.

The second example, Fig. 2, illustrates a 34 in. Spartan double belt handling a heavy drive at the Railroad building in St. Paul, Minn. Note the idler pulley used and its method of adjustment. Both these photographs are reproduced through the courtesy of the Canadian Graton and Knight, Ltd., of Montreal, Canada.

It will be noted that two different style belts were used in these cases, which once more proves that the belt used depends entirely upon condition. In some cases a belt is specially tanned to resist exposure, steam, oil, chemical fumes, etc., and it is always a safe plan to state your conditions to a reliable belt manufacturer and secure his opinion as to the style of belt to use.

Fig. 3 is merely shown as an example of neat belting arrangement. Note how the lathes are set at a definite angle and the belt drive arranged according. Personally we prefer a straight drive to the twist drive depicted, but in this case shop conditions were such that the style illustrated was absolutely necessary, the saving in floor space alone being considerable.

The last example, Fig. 4, illustrates a good arrangement of belting. As the photograph is self-explanatory we need not dwell upon the matter.

To depict all the conditions of belt drives would take a volume, but enough has been shown for practical purposes.

In conclusion we would strongly emphasize the need of caution in the choice of any belt drive. Study it, weigh the conditions carefully, see if the load is steady or irregular, and above all, get to know the merits of the various styles of belts, both leather and fabric. It is only by being conversant with such conditions that one can expect belt satisfaction.

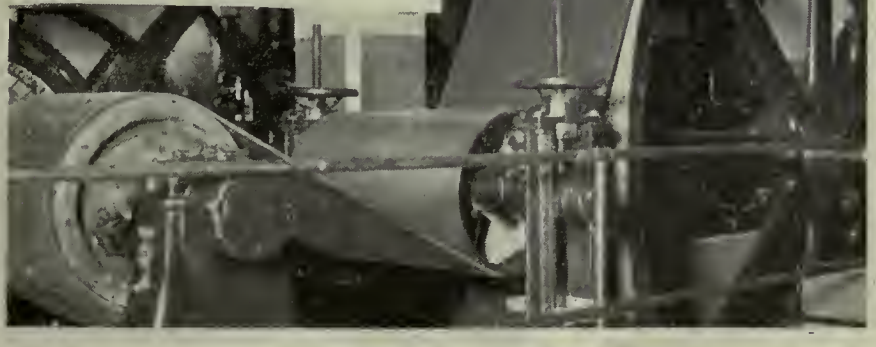

FIG. 2—A 34" DOUBLE BELT HANDLING A HEAVY DRIVE.

RECOVERING OIL FROM SHALE

By E. R. Hassrick

The next ten years will see a revolution in the use of raw coal, and oil shales will be used extensively in oil recovery, according to a statement by Dr. George H. Ashley, chief of the Topographic and Geological Survey of the Pennsylvania Department of Internal Affairs.

Believing that the increased consumption of oil and gasoline in this country will necessitate the finding of additional sources of supply, he has commenced a study of the possibilities of recovering oil from shales. The use of shale for distillation purposes, according to Dr. Ashley, is an extremely expensive proposition, and he believes that this method of procuring oil for the making of gasoline will hardly be brought into general use until the price of gasoline reaches 50 cents a gallon. At the present time, he says, there has been no decrease in the supply of oil and gasoline in the country, but rather a continuous increase in production. During the last year, however, the demand has exceeded the supply, and the country's reserve stock has been considerably reduced.

In addition, it has been necessary, on account of the exportation of gasoline from this country, to import it from other quarters. He also points out that, although there has been an increase in oil production in this country, the initial production of oil in new wells has been far below the initial production of wells in years gone by. With increasing costs of machinery and operation and a smaller initial flow from new wells, he believes that the present high price of gasoline can, in a measure, be attributed to these items.

In discussing the possibility of securing oil from coal, Dr. Ashley says: "Today, except for metallurgical purposes, we burn coal in a raw state, wasting, when used for power, from 80 to 95 per cent. of the heat and energy in the coal, and all of the oil, gas, tar and other by-products, except as they are burned in the fire. "It may be safely predicted that the next ten years will see a revolution in our use of raw coal. Already the by-products coke oven is replacing the old bee-hive oven. The coke is made by the distillation of bituminous coal at a high temperature, around 1,200 degrees F., the by-products being used for heating and illuminating, tar and ammonia. If, however, bituminous coal is distilled at a moderately low temperature, below 750 degrees F., the quantity of gas given off is reduced and coke is replaced by a smokeless fuel, called in one process 'coalite,' having the same heating value as an equal weight of coal, and—oil.

Products Obtained

"A plant operating in England with English coal is reported as obtaining from one ton of coal three gallons of motor spirits suitable for every purpose for which gasoline is used, 16 gallons of oil similar to crude petroleum, which can be used for burning, light, lubricating or for distillation; 7,000 feet of gas, richer in heat and higher in candle-power than ordinary coal gas; 20 pounds of sulphite of ammonia for fertilizing and high explosives, and 1,400 pounds of smokeless fuel.

"Contrasting these figures with those showing the production from by-product coke ovens at high temperature in the Pittsburgh district, it should be noted that these ovens give only 1,100 pounds of coke and no oil, but give 300 pounds of tar and only six and one-half pounds of ammonia sulphite, three gallons of benzol and 7,000 feet of gas."

Pennsylvania is at this time mining about 180 million tons of bituminous coal a year. "If one hundred million tons of that were first passed through such a process as that mentioned," continued Dr. Ashley, "it would increase our oil supply by over one billion gallons, and, remembering that smoke is unburned coal, it may be questioned if the 'coalite' left over and the distilled gas would not supply nearly or quite as much heat as the one hundred million tons of coal."

A Danish company proposes to develop some iron ore deposits in the north-western peninsula of Iceland. These are said to contain from twenty to thirty million tons of ore. The material is a brown oxide containing from 40 to 55 per cent. of Fe, and lies at a height of some 1,000 feet above the base of the basalt rocks.

Using Rock Drills in the Industrial Plant

The Modern Machine Shop and Industrial Plant Find Many an Awkward Job Which Can Be Easily Accomplished by Use of Such a Tool as Described Herein.

By F. A. McLEAN.

IN the installation of conduit for electrical wiring, gas, water, steam or air pipes, in the erection and re-erection of motors, generators, machine tools, crane runways, shafting, etc., in the fitting of steel door frames, window sashes, buffers, corner plates, in the modern machine shop or factory, the electrician, the plumber, the steamfitter, the millwright, the master mechanic and the mason, often find it necessary to drill holes of various diameters and depths in stone, brick or concrete walls, ceilings, floors, columns, stanchions or foundations.

The usual method of drilling these holes with a hand steel and a hammer is by no means satisfactory for several reasons. Hand drilling, whether it be in stone, brick or concrete, is a slow and monotonous job of which men soon tire. Then it is almost impossible to strike the steel with a uniform blow and the holes vary widely in diameter, often being larger than actually needed, or are of irregular shape and require a lot of patching up with cement or mortar. This makes an unsightly job, examples of which may be seen by glancing at the chinks or dabs of mortar around pipes or bolts protruding from the walls and foundations of many manufacturing plants.

Where there are a number of holes to be drilled or a portion of the plant is forced to remain idle, pending the drilling of anchor bolt holes, the cutting or trimming of rock for a foundation or the installation of wiring or pipes to accommodate some new piece of equipment or change in the location of a motor, boring mill, lathe, drill press or pump, the cost of drilling the holes by hand is likely to be excessive and in some instances may be greater than the cost of the power drilling equipment necessary to do the work.

ANOTHER USE TO WHICH THIS STYLE OF DRILL CAN BE PUT.

Hand rock drills of the standard Jackhamer type have been successfully used in a number of plants for the heavier forms of this kind of work for several years. A notable example of their value in this respect occurred during the rebuilding of the Thomas A. Edison plant at East Orange, N.J. On this job it was found necessary to drill 9,500 holes in the concrete walls to take expansion bolts used for holding the steel window frames in place. Through the use of the Jackhamer the work was accomplished in about one-fifth of the time that it would have taken by the hand method.

With the exception, however, of such jobs as cutting large hard rocks for engine and machinery foundations, digging holes, boring frozen ground or tearing out old concrete or masonry foundations, most of the rock drilling requirements of the average factory or machine shop can be met by a somewhat smaller and less powerful drill than the regular Jackhamer, which is a little too heavy for light work and is not as easy to handle when drilling overhead as a smaller tool would be.

With this idea in mind, the Canadian Ingersoll-Rand Company has recently brought out a new drill of the Jackhamer type, known as the BAR-33, or Industrial Jackhamer, and also a simple attachment whereby the larger sizes of their "Little David" chipping hammers may be rapidly and easily converted into light hand drills or "plug drillers" as the small drills used for plug and feather work and other light drilling jobs by stone masons and monumental workers are usually called.

This Industrial Jackhamer weighs only 21½ pounds, uses ⅞-inch hollow hexagon steel with bits of up to 1⅝-inch., consumes 34 to 55 cubic feet of air per minute at pressures of 60 to 100 pounds and is adapted to all forms of drilling

THESE THREE VIEWS SHOW VARIED USES FOR THIS TYPE OF DRILL.

where the rock is not excessively hard and the depth of the holes required is not over five feet. Its light weight and small over-all dimensions relieve the operator from unnecessary fatigue and enable him to drill a far larger number of holes in a given time than can be done by the best hand driller and to reach places that he could not get at with a larger and heavier machine.

In general design this new drill resembles the company's standard BCR-430 Jackhamer, the valve mechanism being similar. All ports are short and direct, the inlet being separate and distinct from the exhaust. The rotation is simple, sturdy, automatic and positive. A rifle bar and ratchet are located in the back of the cylinder and impart a rotary motion to the piston which in turn rotates the chuck holding the drill steel, on much the same principle as that made use of in the ordinary automatic screw driver. The handle, front head, through bolts and cylinder of these drills are drop forgings and other parts are made from special alloy steel. The photographs accompanying this article illustrate a few of the ways in which these drills are made use of in industrial plants.

In the small plant where there is only an occasional need for drilling holes in stone, concrete or brick, and only a few holes are required at any one time, the "Little David" plug drilling attachment will be found useful. When applied to a No. 3 or No. 4 "Little David" chipper, a simple plug driller is formed that will drill ¼-inch to ¾-inch holes to a depth of six or eight inches at a rate of speed that far eclipses hand work, and when the required number of holes have been drilled, the tool is quickly converted into a chipper again ready to do the work usually done by these tools. In addition it may be used for toothing out bricks, enlarging drilled holes, dressing up concrete and stone, etc.

The plug drilling attachment consists of an alloy steel bolt constructed so that a portion of the air from the exhaust of the drill is deflected and carried through a short hose to a special blowing attachment which clears the cuttings from the hole, a rotating wrench and a bit of such size and shape as will be most suitable for the work required, complete the equipment. As shown in one of the accompanying photos, the tool is held in one hand and a semi-rotary motion imparted to the rotating wrench by the

THE EASE OF HANDLING IS SELF APPARENT

free hand, thus ensuring the ultimate roundness of the finished hole.

It is perhaps needless to point out that while the largest sized bits that are recommended for use with the Industrial Jackhamer and the plug driller are respectively 1⅝-inch and ¾-inch, neither tool is limited to the production of holes of these diameters or under, since a number of holes can be drilled very close together and the intervening webs then broken out by a few sharp blows from a hammer, by chiseling or wedging or by holding the tool against them and turning on the air, allowing the vibration of the tool to break them loose. Large holes drilled or cut in this way are generally more regular in shape than those drilled with the hand steel and their size is subject to more accurate control.

In machine shops or manufacturing plants operating foundries, both the Industrial Jackhamer and the chipper used to make the "plug driller" can be adopted to knock out cores and clean the sand from all sorts of castings and will do as much work as two or three men could do by hand. When using the Jackhamer for this purpose it may sometimes be found desirable to remove the rotation pawls so that the "steel" or "bit" does not turn. The Jackhamer will handle steels up to five or six feet in length, permitting the removal of cores from engine and machine tool frames or other heavy castings, while the chipper is better suited to use on smaller and more intricate work, although in large plants where there is a considerable amount of core breaking to be done, better results are sometimes obtained by tools designed especially for this purpose.

DETAILS OF THE DRILL ITSELF.

BRITISH OIL ENGINE PIONEERS

The way in which a name, whether good, bad, or indifferent, sticks to a thing which has once received it is illustrated by the Diesel engine. In many vital respects the modern oil engine as used for propelling ships and for generating electricity is distinct from the type invented by the late Dr. Diesel, but people go on calling them "Diesels" as if the German inventor were the father of them all. There is a good deal in a name when applied to an engine in common use, because a wrong name not only gives a mistake notion of the machine but it does an injustice to the real inventor. This point came up at a recent meeting of the British Institution of Mechanical Engineers, when a paper on the progress of oil engines was read. It was there pointed out that the so-called Diesel engine was really the Ackroyd Stuart engine, as a British inventor of that name had, long before Diesel's day, worked out the principles on which large oil engines could be made to work satisfactorily. British engineers feel that it is the name of Ackroyd Stuart and not that of Diesel which should be immortalized in connection with this great branch of engineering.

GIANT FLOATING CRANE

A floating crane recently supplied from Great Britain to an Australian dockyard is one of the giant cranes of the world. It is capable of lifting a load of 150 tons and swinging it within a radius of 90 feet. In this British design the whole of the deadweight is carried on a large "roller path" fixed to the deck of the pontoon and not on the top of the steel tower which rises from the centre of the pontoon. Dangerous stresses are thus avoided, material is saved, and the life prolonged. The crane has been officially tested up to 200 tons with complete success, all the performances calculated for by the builders having been realized. No moving ballast is used in the pontoon, and at no time is the angle of tilt more than about four degrees. Two cranes of a similar type have been at work in the same dockyard for six years. A noteworthy feature of the crane is that, although designed for heavy loads, it handles light loads with ease and rapidity. All the machinery on board is electrically driven, power being obtained from a steam dynamo or from shore by means of a flexible cable.

Do You Know That Steel Melts from the Inside?

The Author, Who is the Discoverer of the Fact That Steel Melts from the Inside, is Allowed in This Article to Tell His Story in His Own Way.

By G. P. BLACKISTON.

NEW things continue to happen, new inventions continue to be found, and new discoveries are occasionally made despite the oft heard proverb "There is nothing new under the sun." Perhaps in no field more than in the steel field have greater, more far-reaching discoveries of scientific value been made in recent years. Only twenty years ago a man, whose name is found in the records of mechanical achievement, made the momentous discovery that steel containing certain alloys possesses an entirely new and distinct property, called red-hardness. It was about this time that F. W. Taylor stumbled, as it were, while engaged in a work of an entirely different nature, upon this remarkable fact, a fact of so much importance that the new steel, which became known as high-speed steel, was the impetus that was responsible for the revolutionizing of the then common manufacturing processes. For this new steel was able to remove metal, when shaped into cutting tools, at so fast a speed and feed and at a depth of cut so great, that truly the world was astonished when its properties were demonstrated.

And now comes a gentleman named G. P. Blackiston, and announces to the world that steel melts from the inside. Like Taylor's, Blackiston's discovery was an accident. We do not know what its value will be to the steel trade but will tell the story as it comes from the lips of Mr. Blackiston himself, whose desire is to give the information freely and let all who may profit from it.

Mr. Blackiston is a practical steel man, and made this discovery while at work in a crucible steel plant. As is well known in the manufacture of crucible steel, the mixture for melting consists of definite and carefully weighed amounts of certain grades of wrought iron, blister bar, alloys and scrap which are packed in pots. These pots, when filled and covered, are placed in a furnace which contains a number of holes—six pots, three deep and two abreast, being placed in each hole. The holes are then covered and the pots are subjected to a heat of about 3,000 degrees F., for a period of from two to three hours. After the mixture is melted, the pots are allowed to stand in the furnace until all the gas in the solution has boiled out and the molten steel is then ready to be cast.

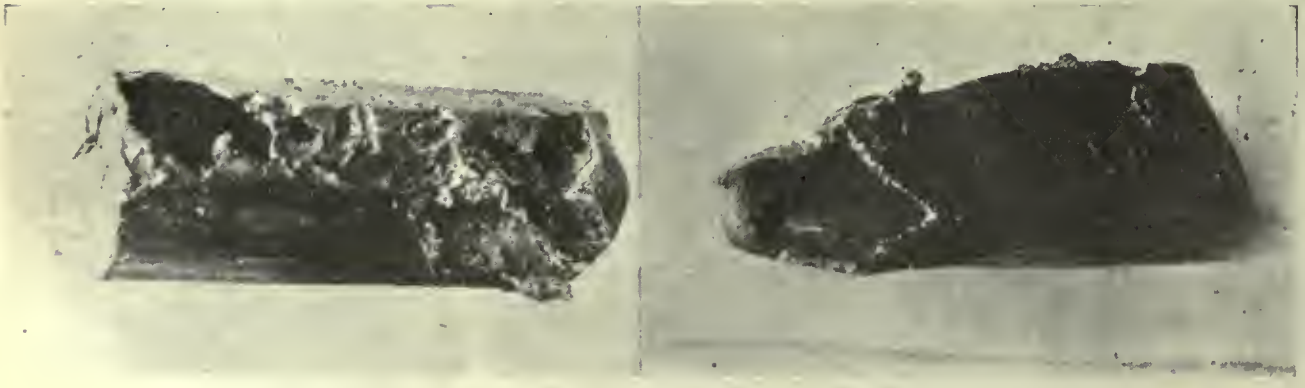
In the mixture used at the time that the discovery was made, numerous pieces of octagon bar steel such as is used for chisels, and rectangular bar steel, as used for lathe and planer tools, were found. After the pots had been packed, placed in the furnace, and the melting was well under way, one of the pots broke and was immediately removed from the furnace and set to one side.

Let us examine briefly what was revealed by an investigation into the mass of metal found in this broken crucible, which had been subjected to the high heat of 3,000 degrees F. for a short time. After the pot had cooled, it was observed that chunks of metal were present which seemed to have the original shape they possessed at the time they were inserted in the pot. By tapping them with a hammer, a hollow sound was noticeable and upon further investigation the pieces were indeed found to be hollow. They were carefully removed and are shown in the accompanying photographs, Figs. 1 and 2. It will be observed that the pieces removed from the pot are two hollow shells that have retained their original contour, except that in the process of melting the molten metal in the inside found a weak spot in the outer shell and passed out through the opening shown.

The reasons for this are not so obvious. As is well known, pure iron has a higher melting point than steel and the more carbon there is in the steel, the lower its melting temperature. The outer layer of these bars of tool steel received the heat first, but this heat was, no doubt, immediately transferred to the inner portion, as the heat continued to be added, it is believed that the carbon was burned out of the outer layer and that it became, in fact, a low-carbon steel approximating iron itself. The inner layer still retained its carbon and would, of course, melt at a lower temperature, which explains why it had entirely melted, while the outer layer was intact. This important discovery was, of course, due to the accidental breaking of the pot containing this certain mixture just at the right time; and the subsequent handling and investigation revealed this interesting phenomenon. We do not state where this discovery may lead to, but perhaps the principle may be applied to the manufacture of articles, now made in an entirely different manner, in a new and cheaper way.

MEASURING MACHINE

A microscopic measuring machine has been placed on the market by Alfred Herbert, Limited, of Coventry, England. The machine is mounted on a rigid box bed, and the table carries a pair of centers, one of which can be adjusted sidewise for accurate alignment of the work. The reading of the instrument is accomplished by the relative position of the two cross hairs that are fitted to the microscope, one of the hairs rotating with the outer tube and the other with the eye piece. The outer tube has a dial graduated in half-degrees and the eye piece has a vernier reading to one minute of arc. Accurate reading is obtained by the angular position of the two cross hairs. The machine is likewise fitted with a light projector.



HERE ARE THE PHOTOS ON WHICH THE AUTHOR BASES HIS CLAIMS.

Have You Been Reading About This Society?

By J. H. MOORE

CONSIDERABLE interest is being shown in the recent formation of the Federated American Engineering Societies in the United States, and for our readers' benefit we will tell briefly what has transpired.

On June 3 an organizing conference was held at Washington, with the result that the new society came into being. About 75 branches of the engineering profession were represented, and this alone tends to show the solidity of the movement. It has been apparent for many years that with the constant increase in number of engineering and allied technical societies, each carrying on its work independently of the others, that some form of comprehensive organization was desirable which could speak for these societies in matters of common concern. There were frequent occasions where united action by these professions was desirable, and as a result of a serious need to meet the conditions arising from the war, the Founder Societies created an engineering council—"to provide for the consideration of matters of common concern to engineers as well as those of public welfare in which the profession is interested in order that united action may be possible." This was affected through the agency of the United Engineering Society, of which Engineering Council was made a department. In February, 1919, the American Society for Testing Materials became the fifth member and the American Railway Engineering Association was admitted as the sixth member in April, 1920.

The Engineering Council held its first meeting in June, 1917. It has a chairman, two vice-chairmen, who with three other members elected by the council constitute an executive committee. Its officers and members of its 24 committees, membership on which is not limited to representatives on the council, total 125 engineers representing all parts of the United States.

The appointment by the four founder societies of committees on development was for the purpose of determining the functions and objects of these societies and of making recommendations as to the changes in their activities that were desirable both as to internal relations and as to their relations to other societies.

Joint Conference Committee

Confreres of the four societies met in August, 1919, and organized as the joint conference committee. The purpose of the latter was to determine in what manner these four societies could co-operate in non-technical or welfare work affecting the relations of the engineer to, and his service in public affairs. The committee presented a report to these societies in September, 1919, and recommended the formation of a comprehensive organization, the purpose of which should be "to further the public welfare wherever technical knowledge and training are involved, and to consider all matters of common concern to these professions."

This plan of procedure was approved by engineering council at its meeting in October, 1919; the joint meeting, held in New York in January, 1920, of the members of the governing boards of the four founder societies and of the American Society for Testing Materials, the members of Engineering Council, and the trustees of the United Engineering Society, unanimously requested the joint conference committee to call, without delay, a conference of representatives of the national, local, state and regional and engineering organizations of this country for the purpose of bringing into existence the comprehensive organization recommended by the joint conference committee.

The Organizing Conference

At the organizing conference held in Washington, June 3 and 4, 1920, in response to the call issued by the joint committee, representatives of about 75 engineering and allied technical organizations created the Federal American Engineering Societies and provided for the administration of its activities by the American Engineering Council and its executive board. The constitution and by-laws adopted were substantially those recommended by the joint conference committee. At its session of June 4, the following resolution was unaimously adopted:

Resolved: That it is the sense of this organizing conference that the joint conference committee should be entrusted with making provision for putting the conclusions of this conference of engineers into effect, and that engineering council be requested to carry on its work until the new organization has been established, and by all proper means to further the programme of the new organization. The conference further recommends to the contributing societies that they continue supplying the funds required by engineering council until its work is taken over by the new organization.

Thus the way has been opened for the American Engineering Council to succeed Engineering Council as soon as the former is ready to take over the work that the latter is now doing, which will probably be on January 1, 1921.

What of Engineering Council?

In view of this fact it will be of interest to review briefly what Engineering Council has accomplished in its three years of existence. Under the terms of the charter granted by the State of New York to the United Engineering Society, Engineering Council has defined the field of its activities as follows:

"Council may deal with any matter of general interest for which joint action of two or more of its member societies would have been appropriate, if council had not been established. Council may initiate and carry through projects of the general character defined in the by-laws, for which the necessary financial provision has been made.

"Council may take up, and in its discretion act upon, any matter of general interest referred to it by any member society or by any other society, national, state or local, or by any branch of government, or by any individual or group of individuals."

In a circular issued in December, 1919, outlining the "Aims and Work of the Council," in discussing what it has done, the following statement is made:

"Council's greatest contribution, possibly, although little known, because indirect and intangible, has been the development through its own discussions and those of the governing bodies of its member societies, of the problems involved in bringing together for united action the fragments of a profession so much broken by specialization as is the profession of engineering."

The working together of committees of representatives of the several member-societies of engineering council has unquestionably had a leavening influence for the betterment of the engineering profession, and the council has certainly accomplished a work of incalculable value in initiating the joint work of these societies.

It was not until seven months after its organization that funds were available for carrying on the work. The secretary states: "For 1918, the appropriation for council averaged 40 cents, and for 1919, 60 cents per individual member of the member-societies." With this limited support we have accomplished a great deal of work.

Field of the Federated Societies

The questions are frequently asked: "What will be the field of activity of the Federated American Enginering Societies?" and "What does the organization intend to do?" The work of this organization will be a kaleidoscopic character, with few fixed lines of activity, its major work depending on conditions as they arise from time to time; it will take over and extend the work of Engineering Council.

What it intends to do is to use its power for the service of the community, state and nation in public affairs wherever engineering experience and tech-

(Continued on page 288.)

A Talk on the Art of Practical Casehardening

The Author of This Article is Well Able to Speak of the Subject, Being a Recognized Authority—He Once More Emphasizes the Importance of the Man as Well as the Method.

By THEODORE G. SELLECK

IN concluding this series of articles on the subject of the casehardening of steel, the writer wishes to emphasize the point he has tried to make clear throughout the article,—no matter what the method of operation employed, *the Man is More than the Method.*

We may give all the instructions for the operation of the process of carburization that are known, practically or theoretically, and with the most complete details of procedure, and yet such instruction cannot be so exact that the human element is not the largest factor in the successful operation of the process.

The most complete specifications for the carbonizing of steel yet published are those of the American Society of Automotive Engineers, and a close study of them reveals just how much is left to the judgment of the casehardener. These specifications have been compiled as the result of the experiences and experiments of many expert engineers and are, undoubtedly, the best guide we have for the casehardening of automotive parts.

As an example of what is meant by the assertion that even these specifications are in nowise complete and that much is left to the judgment of the operator, let us consider one of the specifications,—that for the treatment of ".20 per cent. Carbon Steel,"—which is used in casehardened parts more than any other type of steel. The specification follows:

"1. Carbonize at a temperature between 1600 degs. F. and 1750 degs. F."

"2. Cool slowly or quench."

"3. Reheat to 1,450 degs. F. to 1.500 degs. F. and quench."

The wide range of temperatures for carbonizing, the advantage of the direct quench or slow cooling, the time the parts are to be held at the carbonizing temperature, the nature of the carburizer and every practical detail is left to the judgment of the operator. It cannot be otherwise in the operation of our present system of carburizing.

There are many variables to be considered: Variations in the chemical constitution of the steel; even the specifications demanded by the S. A. E. allow a variation of ten points in the carbon content of the steel just mentioned and thirty points variation in the manganese content. This wide range of temperatures is to provide for those variations and also to meet the varying qualities that may be desired in the "case," the depth of penetration, etc.

The specifications mention that the above treatment is sufficient for a certain class of work, "such as gears, steering-wheel pivot-pins, cam-rollers, push-rods, and many similar details of an automobile." But if we were to step out of the automobile industry and wished to use the process for something foreign to that line, the above instructions would not be particularly helpful unless the casehardener possessed sufficient knowledge and judgment to make a comparison between that line of work and the work he wished to treat. The simple treatment given above is used on a much wider range of work than the S. A. E. suggests it may be used for and, in many cases, with perfect satisfaction, but in more cases with losses and failures that should convince the operators (who fail with it) that they should change methods; but there are some who are so determined that double-treatment of case-hardened parts is not necessary; that they persist in the single-treatment when they have a constant, and sometimes heavy loss.

Double-treatment for the same steel is specified as follows:

"1. Carbonize at a temperature between 1600 degs. F. and 1750 degs. F.

2. Cool slowly in the carbonizing mixture.

3. Reheat to 1550 degs. F. to 1625 degs. F.

4. Quench.

5. Reheat to 1,400 degs. F. to 1,450 degs. F.

6. Quench.

7. Draw in hot oil at a temperature which may vary from 300 degs. F. to 400 degs. F., depending upon the degree of hardness desired."

In these operations, seven in number, we have the most complete and perfect method for the heat-treatment of casehardened parts; however, there are but three of the seven operations that are not left to the judgment of the operator, (2, 4 and 6). In the other four the operator must follow his judgment as to the proper carbonizing temperatures, quenching temperatures, and drawing temperatures; these are naturally the most important factors of the process and upon the proper choosing of them depends the success of the operation. Most operators know that the same piece, or the same quality, of steel carbonized at 1600 degs. F. for eight hours will have quite a different quality of "case" than it will possess if carbonized for the same period of time at a temperature of 1750 degs. F., and it is up to the operator to determine the exact carburizing temperature which will give him the quality and depth of case he desires. If he knows his steel and his carburizer, he may be able to determine these points without making preliminary tests, but in most cases they can be determined only by experiment.

There are other types of steel that require the same treatment as that given above; in fact, it is a sort of standard treatment that may be followed almost universally for steels of the same carbon content, the operator being the judge of the proper heat to apply within the wide range allowed. Steel castings are left out of the list of S. A. E. specifications, but the writer has followed the above single-quench method very satisfactorily on such parts. But if a casehardener is not experienced, he may have a world of trouble trying to follow the same method, because of the variations in the quality of the castings. The double-treatment will hardly ever fail, and the "drawing" may, in most operations, be omitted.

There are times when a case hardener is called upon to carbonize steel of higher and lower carbon content than that given above.

Steel carrying less than 10 per cent. carbon is not used for machined parts to any extent, or seldom for forgings; consequently, it is rarely used as a casehardening steel; there are some uses made of it, however, where it is advantageous to carbonize it. It may be carbonized at much higher temperatures without danger of injury to the "core" than steels of higher carbon content, and for that reason is sometimes used for the manufacture of agricultural steel, for such parts as cultivator-shovels, plow-shares, plow-moldboards, etc. This steel, when carbonized at a temperature between 1650 deg. F. and 1750 deg. F. will stand considerable working at high temperatures, such as forging, welding, and forming, without losing any appreciable amount of its carbon content, and at the end of the shop operations will, by the application of the double-heat treatment, develop a very tough "core" and a very hard surface. Where this steel can be used, single-heat treatment is sufficient, if the carburizing temperature has not been carried above 1650 deg. F. If the quality of the case is not of much importance, quenching direct from the pot will be the only treatment necessary. If a more refined case is desired, it will be better to let the parts cool down in the carburizer and reheat to 1450 deg. F. and quench.

It is sometimes necessary to carbonize steel with carbon content as high as .20 to .30 per cent. Such steel should never be carbonized except as an emergency, and the most painstaking care should be used in the heat-treatment,

*Fro mthe Journal of American Steel Treaters' Society.

which should always be the double-quench and draw method.

Alloy steels require only slightly different treatment than that given the plain carbon steels.

Points to be Watched

Nickel steel, containing 3½ per cent. nickel and .10 to .20 per cent. carbon, will take practically the same treatments as the S. A. E. 1020 except that the second quench should be carried out at somewhat lower temperatures. In the use of this steel the treatment depends upon the character of the parts to be carbonized. This steel is used extensively in the manufacture of gears and these should be very carefully quenched, and drawn, if the highest quality is to be established in the finished gear. The second quenching temperature should be as low as can be used and get the necessary hardness of the case. Where the hardening temperature for plain carbon steel is given as 1,400 deg. F. to 1,450 deg. F. it is given as 1300 deg., so it is wise to do a little experimenting before adopting a temperature for the refinement of the case. Parts of irregular shapes and thickness should be drawn in oil at from 250 deg. to 500 deg. F., according to the degree of hardness required.

Nickel-chromium steels of the usual analyses require the same treatment as the plain nickel steels but must be more carefully watched during the carburizing operations as they are carburized more rapidly than plain nickel.

Chromium-vanadium steels are the best casehardening steels we have so far as the process of carburizing goes, although there are steels better adapted to certain parts.

The carbonizing temperatures for these steels are the same as those recommended for the plain carbon steels. but the quenching temperature for the refinement of the core should equal the carbonizing temperature. That is, if the steel is carbonized at 1650 deg., the first quench should be at that temperature, the metal being reheated after cooling down in the carburizer. For the refinement of the case a temperature between 1475 deg. and 1550 deg. is recommended. For the most particular class of work a "draw" at 250 deg. to 550 deg. is indicated.

These specifications, compiled and issued by an organization of highly technical men, seem unnecessarily indefinite, but as a matter of fact that are as precise and definite as can be laid down for the treatment of a metal that comes so far from being regular and constant in its chemical constitution; and until steel can be manufactured to exact analyses, and present variations of carbon and its other elements are eliminated, we shall have to have flexible rules for its treatment.

In following these, or any other, instructions, for the heat-treatment of steel, the operator should have as an aid a good pyrometer, and be always sure that it is in proper working condition. The inexperienced steel-treater will find considerable difficulty in arriving at conclusions concerning the accuracy of his instrument unless he has some means at hand for checking it. Usually an extra thermo-couple is kept for that purpose and by it the regular service couples are checked at very frequent intervals, sometimes as often as every day. This is by far the best way and the simplest.

With the pyrometer, the steel-treater should equip himself with a "color chart," giving the temperature values of the various heat colors. By making comparisons between these colors and the temperatures indicated by the instrument he soon gains a knowledge of colors that will enable him to readily observe any important error in the reading of his instrument.

A color-blind steel-treater would seem to be about the last anomaly we would look for in the working of steel, but they exist altogether too commonly. Some are not entirely so and yet sufficiently to make the accurate working of steel a mere chance, while others cannot discern the difference between the primary colors, to say nothing of their various tints. This latter class rest entirely upon the pyrometer, of course, and if their instrument goes wrong their work is sure to do so. For that reason, employers of steel-treaters should insist upon an examination for such optical defects before they allow a man to function in the treatment of steel parts that require positive and careful handling at high temperatures.

For inexperienced case-hardeners who do not know the value of the more common colors and tints as expressed in temperature, the following tables are given. These should be supplemented by color charts showing the actual colors. There are several of these that may be obtained from manufacturers of pyrometers and heat-treating equipment, without cost.

Degrees Centigrade	Degrees Fahrenheit	Color
400	752	Red heat, visible in the dark.
474	885	Red heat, visible in the twilight.
525	975	Red heat, visible in the daylight.
581	1077	Red heat, visible in the sunlight.
700	1292	Dark red.
800	1472	Dull cherry-red.
900	1652	Cherry-red.
1000	1832	Bright cherry-red.
1100	2012	Orange-red.
1200	2192	Orange-yellow.
1300	2372	Yellow-white.
1400	2552	White welding heat.
1500	2732	Brilliant white.
1600	2912	Dazzling white.

It is conceded by the best authorities that the most skilled observers may vary as much as 100 degrees Fahr. in their estimation of relatively low temperatures by color, and beyond 2,000 degrees Fahr. it is practically impossible to make estimations with any certainty. So that the use of the color chart is limited, practically, to the use it may be in giving warning of the failure of the pyrometer, and the judging of the uniformity of the temperature throughout the heating chamber of carbonizing furnaces.

In reheating, for hardening case-hardened parts, the liquid bath offers the best means of heating the parts uniformly, because the temperature required may be easily maintained and none of the parts can ever get hotter than the bath.

The materials for such baths most generally used are molten lead, mixtures of barium and potassium chloride, barium chloride, cyanide of potassium, and other metallic salts. These various baths are adapted each to a certain range of temperatures. The lead bath for instance, may be used for temperatures between its fusing point and about 1,200 deg. F., above which it is not practical because of the volatilization of the metal at that temperature; lead is chiefly used for "drawing" operations, and as a quenching medium for "high speed" steel. For temperatures between 1,400 deg. and 1,650 deg. F. a mixture of 60 per cent. barium chloride and 40 per cent. chloride of potassium may be used, or, 50 per cent. calcium chloride and 50 per cent. sodium chloride; these chloride solutions have one very bad property however, and that is the rusting of the material treated in them. This may be overcome by washing the parts in a solution of soda after quenching in clear water. A better heating solution, or bath, is a mixture of soda-ash and the common commercial cyanide-chloride mixture containing about 75 per cent. of sodium-cyanide, in proportions of 60 per cent. of the former and 40 per cent. of the latter. This gives a solution containing about 30 per cent. of cyanide.

In the use of any of these solutions, or baths, the furnaces should always be provided with ventilating hoods for carrying off the fumes and gases from the operator. Even lead yields a very poisonous gas when subjected to a volatilizing temperature.

Preheating Necessary

In the use of these heating baths the work should always be preheated to about 800 degrees before immersing in the solution, otherwise the solution will be so chilled that the operation will be greatly slowed up. Some pot furnaces, specially designed for such work, have special pre-heating chambers attached that permit of doing that part of the work by the use of waste gases from the furnace, so there is no extra expense attached to the preheating.

Parts heated in solutions should be suspended on hooks or in baskets from the top of the pots, and should not be allowed to touch the bottom or sides of the pot.

The pyrometer thermo-couple should be protected by a pure nickel protecting tube and should extend well into the pot without touching the bottom. Care should be observed in the matter of overcrowding the pot as work can be done more rapidly if the volume of solution is much larger in proportion than the volume of metal being heated.

In applying the carburizing process to any class of work it should be always borne in mind that each particular form

of parts to be carburized constitutes an individual problem in the art, and should be so considered, and its particular method of treatment should be worked out, without any reference to the methods applied to any other part. In other words the treatment best adapted to the carburization of cam-shafts is not suitable for wrist-pins, and the treatment best adapted to ball-races will not answer for very light bushings, caps, etc., and any operator of the process who knows of but one method to follow, one carburizing temperature to use, and but one quenching temperature to apply, is in line for a lot of trouble and loss.

With all the information that he can obtain from others, either by word of mouth, demonstration, or through the medium of books, the case-hardener will find himself frequently confronted with problems for which he has no answer. So it becomes the operator of the process to be always studying his art, even to making problems and finding their solution.

The writer is frequently consulted by casehardeners concerning various questions relative to the successful carburization of certain parts with which they have difficulty. Some of the questions asked are so very simple that it would seem that a man of just ordinary intelligence would not need to ask them, while others are so deep that the only answer that can be given is the suggestion that the successful treatment of certain important automobile parts depends entirely upon the development of new methods of carburizing.

The carburizing process is of so much importance in the manufacture of certain lines of the common necessities of life, as we are living it these days, that it cannot be allowed to linger in its present very incomplete stage of development. It must keep pace with the other important branches of steel-treatment.

When we consider that, as it is commonly applied, the operation of the carburizing process involves the use of more than double the fuel that should be required; that the containers used to hold the work, on the average, weigh more than the metal parts they contain, which means added labor, increased furnace capacity, and increased wear and tear; that the important, perhaps we should say the all-important, quality of uniformity, is difficult to realize under present conditions; the necessity of bringing out a new process is apparent.

At present we have no adequate system of heating carburizing boxes. The practice of placing them in the semi-muffle furnace, usually so constructed that the uniform distribution of heat is a problem greater than the average operator can solve, generally results in some of the boxes getting vastly more heat than others, frequently to the utter destruction of some of them while others are not heated above the necessary carburizing temperature. Recently the writer was "on the job" when one of a charge of four boxes in the furnace was partially melted while the other three were not at an excessive temperature, the cause in this case being the improper placing of the oil-burner from which a needle flame shot against the wall of the box. The fault, primarily, was with the manufacturer of the furnace, since the furnace was practically new and such conditions should not have been possible; secondarily the fault was with the operator, because he did not watch his equipment and know whether the furnace was operating properly or not. But the operator being "a greenhorn," and this the first casehardening job he ever had, he could hardly be expected to know that cast iron boxes can be melted in a casehardening furnace. It was a case where the employer believed, as so many of them do, that "any Dub can caseharden steel," and this man fitted the appellation to a nicety.

Metal containers for the carburization of steel, as they are now used must eventually be discarded and new methods of applying heat be developed before the process can come into its own and reach its highest point of usefulness.

We must get away from the thought that experience, intelligence and carefulness are not necessary qualifications in the selection of men to operate the process, however, before any improvements will be of the least advantage to us. We may be able to eliminate the man to some extent, but there will never be a time when the proper operation of the casehardening process, as well as all other branches of steel-treating will not depend upon the direction of an intelligent mind for successful application, and we will always be compelled to admit that **"THE MAN IS MORE THAN THE METHOD."**

THE FEDERATED SOCIETIES

(Continued from page 285.)

nical knowledge are involved and to consider and act upon matters of common concern to the engineering and allied technical professions. In the conduct of many public matters which are essentially of an engineering nature, it is vital to the public welfare that engineers and allied technologists should lead.

There will be an increasing number of questions arising in which the opinion of these professions will be of fundamental value to the welfare of the nation, and it behooves these professions to so support the Federated American Engineering Societies that it may so function as to supply this great public need. It is only the exceptional individual of these professions who can fail to see that in increased activities in these broader and less selfish fields the standing of the profession will be greatly improved, and this of necessity must improve the position of the individual engineer.

It is the duty of the engineer to take up public service work. It is incumbent upon him as a citizen to "do his bit," and there is the added responsibility due to his special knowledge and experience which is primarily of importance in the execution of public work.

The Federated American Engineering Societies will speak for a group of citizens who, by reason of special training and knowledge represent a high order of intelligence, and who individually and collectively would be derelict in their responsibility for the talents they possess if they did not apply them unselfishly for the common weal. In unity of action there will of necessity be strength and power. We shall look forward with interest to the progress of this new organization.

HIGH SPEED PUNCHING

Thoughts of the boxing ring are aroused by the title: "The Laws of High-Speed Punching," which belongs to a paper prepared by Captain Tresidder for the British War Office. It deals, however, with a more formidable kind of struggle, as it investigates what happens when a projectile pierces armor-plate. More than a military interest attaches to this question as Captain Tresidder has found that the laws which apply to a shell going through armor plate are the same as those concerned in the ordinary engineering process of punching holes. The extraordinary interest of this problem is suggested by the fact that a candle fired like a bullet will go right through a wooden board without changing shape. Another striking fact is that a 12 inch plate must exert 60 million horsepower in order to stop a 15 inch shell at a range of ten miles. This enormous power is exerted only for one five-hundredth of a second, but in that brief space the plate does more work than a 33-horsepower engine can do in an hour. Many results of great scientific and engineering interest have been attained by the author of this paper, who has worked out an entirely new theory of what happens when a projectile drives a hole through solid steel.

AN IMPROVED HAND VISE

It is a well known fact that the simplest things are the last to undergo improvement. People take them so much for granted that they seldom think about bringing out an improvement upon them. A typical case is the ordinary hand vise, which is used in every workshop all over the globe. It is far from being a perfect instrument, because it works on a hinge and the gripping jaws therefore do not keep parallel as the vise is opened. In spite of this drawback it is only recently that a successful effort was made to turn out a better type. A British firm is making a patent vise in which the hinge is replaced by a right and left-handed screw. When this screw is turned by means of a small wheel the lower end of the vice opens to the same extent as the jaws, which thus remain parallel to each other. With this vice it is possible to hold round articles quite firmly.

It is interesting to know that the annual timber consumption in France is not more than 100 board-feet per capita, or less than one-third that used by Americans. Of the timber required, France imports 30 to 40 per cent.

WELDING AND CUTTING

Welding of a Corroded Boiler Shell*

This Tale Describes How a Corroded Lancashire Boiler Was Repaired by Means of a Portable Electric Welding Apparatus.

By A. K. DAWSON.

HAVING recently had the opportunity of witnessing repairs to a corroded colliery Lancashire boiler by the use of a portable electric-arc welding apparatus, it is the author's intention to describe the method of using this plant, and the work done by it.

The boiler in question was one of a group supplying steam at 100 pound per square inch to Curtis turbo-alternators and other engines. It was 30 feet long by 7 feet 6 inches diameter, and hand-fired. External corrosion had so seriously damaged the shell underneath, between the sludge-pipe mounting and the front end-plate, that the shell was holed through at one point alongside the angle-iron ring, the latter also being seriously wasted away. To remedy this evil, much time and expense would have been incurred in cutting out part of the corroded shell round about the blow-off hole away from the front end-plate, with a view to repair by means of a new cover plate. To secure the latter at a moment's notice would have been by no means easy at the present-day rate of supply of such commodities. Furthermore, it was necessary to renew the lower portion of the angle-iron ring, and a new cover patch would have been to cut, shape, dress, and drill out for the rivet holes in it, as well as in the boiler shell; also, a 7 5-16 in. hole to cut for the sludge-pipe connection. After fitting this plate in position by numerous rivets, it would have to be "caulked" or "fullered," and finished off neatly to leave no roughness.

To save time, and yet make a thoroughly reliable repair, it was decided to build up the corroded shell and angle-iron by means of Messrs. Tilling-Stevens' mobile arc-welding equipment, which is embodied in a petrol-electric-driven motor lorry.

A description in outline of the plant and the method of using it is as follows: A 40 h.p. petrol engine drives the generating dynamo, the current from which supplies an electric motor in connection with the back axle to propel the vehicle when travelling on the road. For welding purposes special switchgear and resistances cut off the current from the motor and convey the electric energy by a pair of flexible cables to the electric arc at the work. On the back portion of the lorry is a twin-cylinder vertical air compressor supplying from 30 to 60 cub. ft. of free air per minute, at a pressure of 100 lb. per sq. in., and driven by a twin-cylinder petrol motor. After standing the lorry in the nearest available position to the work (in this instance about 40 yards), the compressor was used to dress off the corroded surfaces of the steel plating by means of a pneumatic chisel, air being conveyed by a small flexible armored hose; this operation ensured the clean condition of the shell surface for welding, which was then commenced.

First Operation

The first operation was to secure a good electrical contact for the negative side of the arc with some part of the boiler, and this was attained by slightly welding the head of a small iron bolt temporarily on to the face of the manhole collar. The cable from the negative terminal of the switchboard was connected to this bolt, whilst the other cable from the positive terminal at the lorry was joined to a simple pair of steel tongs holding the electrode. These latter are made of Swedish charcoal iron, each measuring 12 inches in length, with a diameter of 5-32 inch, and are smeared with a flux before using. One striking property about them is the amount of bending and twisting they will tolerate without breaking. To commence welding, the end of one of these iron pencils is pressed into the tongs, the handle of which is electrically isolated with insulating tape: the operator places a hand-observation screen of red glass before his eyes, and makes contact with the electrode and the boiler shell. On withdrawing the pencil slightly an electric arc is produced of sufficient heat intensity to fuse the electrode end, the molten particles of which are carried over on to the negative side of the arc —i.e., the boiler shell, which is also rendered intensely hot at the point of contact. Great care is necessary to maintain the air gap between the electrode and the metal to be welded, the most suitable gap evidently being about ⅛ inch or 3-16 inch. If the pencil is allowed to touch the shell for even a second or two a complete circuit is thereby made, and as soon as the air gap ceases to exist, the arc, of course, fails, and the metals cool, with the result that the electrode becomes fixed to the boiler plate. It has then to be broken off and a fresh arc struck. Under such circumstances a heavy rush of current is caused by the absence of the air gap, consequently a steadying resistance and an electrical governor are installed in the circuit on the lorry to reduce as far as possible the current flutuations.

In doing the welding of this boiler, the switchboard at the lorry gave the following information: When no welding was being done, 50 volts, 100 amperes; when the continuous arc was being maintained during welding, 40 volts, 150/200 amperes; when the electrode was permitted to touch the boiler shell, making a closed circuit, 40 volts, 300 amperes.

When welding was done in the underneath side of the boiler shell, the electrode in fusing had the tendency to form molten globules, which were liable to fall off on to the bottom of the flue if the arc were allowed to play at the same point for any length of time. When this occurred the electrode was brought away from the shell, thus destroying the arc, and the soft globules of iron gently flattened against the plating with a hammer. Under average conditions it was possible to use 20 of these Swedish iron electrodes per hour, and for the building up of the boiler-plate in question it took, roughly, 300 of such pencils.

Time Involved

To give some idea of the time taken to complete the work, the welding apparatus arrived at the colliery about noon on one day; the cables, etc., were run out to the boiler, and the corroded steel plating was dressed with the pneumatic chisel in the afternoon, and half the welding done by 7 o'clock that night. By the following afternoon the welding was completed, and the work smoothed off with the compressed-air hammer, whilst the front lower edges of both furnace tubes were also built up where slightly damaged through frequent stoking and raking out of fires. One fitter with his assistant and a boy were with the equip-

My Experience as a Would-be Foundry Foreman

By F. H. BELL

ANYONE who has never had experience as a foundry foreman cannot possibly have any conception of what he has missed. In fact he has missed so much that he is in no position to appreciate how really thankful he should be.

However it must be admitted that the young man who has no further ambition than to remain dormant on a journeyman's job is terribly deficient in self-esteem. My own experiences along these lines have been so extremely interesting to me that I have been forced to laugh about them myself on frequent occasions, and for that reason have thought that perhaps while not posing as humorous or funny, but on the contrary being of a very prosaic, staid disposition, I might, nevertheless, at least amuse others by relating them.

To begin with I served my apprenticeship in a little jobbing foundry which was owned and operated by my father, who I might say was a molder with no mean qualifications. From this it may be inferred that I was a privileged character, which in reality I was—coming and going as I pleased.

I made various trips to other shops throughout Canada and the United States, but always fetching up at home when there was nowhere else to go. The experience gained through these spasmodic jaunts added to the experience which I received at home doing such jobs as attending to the cupola and making cores and so on down the line, imbued me with a store of conceit which led me to believe that there was not much about a foundry with which I was not familiar.

However there came a day when my preordained programme destined that I should say goodbye to my old home town and seek a livelihood elsewhere, knowing this time that I had to make good, as I no longer had a haven to fall back on. Then came the crucial test. With all my good opinion of myself, was I capable of holding a real job? I began to fear that I was not. I had different positions offered me—some in the States and some in Canada, but being a good Canadian I decided to remain among my own, and forthwith selected as my future abode the thriving industrial city of Brantford. Brantford, at that time, boasted of a population of about eighteen thousand, and according to the usual method of accounting—six to a family—there should have been about three thousand families. But, alas! It was not so. There were about two thousand families of six and about six thousand extra or spare fellows. These poor fellows used to spend their evenings standing around in bunches on the street corners, looking at each other until about ten o'clock, when they would turn in for the night, and by half past ten a cannon might be fired down most any street without doing bodily harm to anyone, because there would be no one on the street to harm.

Next to Moscow, Brantford had probably more churches in proportion to its population than any other city in the world, and the inhabitants were of the class that when the vote was taken on local option and a majority of three-fifths was necessary to make it become law, it was carried, all but eleven measly little votes, so it will be seen that the population of Brantford was made up of an exceptionally righteous class of citizens.

As every one acquainted with Brantford knows, it is a city of foundries and practically every boy works at the foundry business. Now here was a city with a superabundance of the highest type of manhood which would have made excellent catches for the fair sex, had there been any of the fair sex to catch them.

Up the shore of the noble Grand River about seven miles was another thriving little borough, by the name of Paris. Here everything was entirely the reverse. The main industry of the town was a knitting mill, which in fact was the largest institution of its kind in Canada. I am not prepared to give exact figures as to how many hands were employed at this establishment, but if they had eight hundred, one hundred would be old and experienced men who had been in the business long enough to be holding such positions as foremen and experts of one kind or another, and would in all probability be heads of families. The other seven hundred would be girls. These girls all had to be of unblemished character, as one bad one would be like a bad peach in a basket—likely to contaminate the whole basket of peaches. Just think of it, hundreds of A1 girls and hundreds of fellows such as we have just pictured and seven miles of country road dividing them. It could not be expected that such a state of affairs could long endure. A bicycle works was started in Brantford which relieved the situation to some extent, by providing the means of lessening the seven mile difficulty and in course of time a trolley line was put into operation which improved matters to a much greater extent. Still all of this was only make-shift and as something real had to be done it was decided that a foundry would have to be started in Paris. Accordingly the proprietor of the mills hit upon the idea of instituting a stock company, consisting of his funds and a few names for fillers and launching into an enterprise known as the Paris Plow Company. A thoroughly modern plow shop was built and a plow maker of renown was imported along with a supply of operatives, and everything was in readiness to be put into full swing with one exception—they required a competent and efficient man to take charge of the foundry and with rare judgment they decided upon me.

I reported promptly at the office and had a lengthy interview with the manager, the result being that I was engaged at the handsome salary of three dollars per day with absolute authority over my department and no interference from anyone. I was shown through the foundry and learned that they had all the floors rammed up, but were afraid to take off a heat and they wanted me to come on at once.

Bright and early next morning I was on the job to put the cupola into commission and get the work poured off. The manager was there also, not in the office, but in the foundry. Of course he was not interfering with me or my work; he was just showing me how to proceed. Before putting up the bottom doors of the cupola he decided that we should try out the fan to see if it was properly speeded. It was set up in accordance with instructions from the makers, but he would take no chances. He had a pressure gauge on the wind pipe and he would have a certain stipulated pressure on that gauge or we would not attempt to run the cupola. By running the fan at the speed mentioned in the catalogue he did not seem to get any pressure on the gauge and he concluded that it was a lucky thing for him that he did not listen to my advice and make a try at it. In order to get off the heat it was decided that some of the machinery in the machine shop would have to be shut off so that we could borrow the pulleys until such time as we could have proper ones brought in. We were not able to make the alterations in time to pour off on that day, but we had a good early start for next day and I had the honor of lighting the fire for the first heat. Of course in the meantime we had put up the bottom doors and put on the coke and iron which made all the difference in the world with the pressure gauge when the blast was put on. Common sense should have dictated to the manager that it would, but common sense appeared to be the one thing which he lacked. However, we got the heat off all right. We had plenty of pressure on the gauge; in fact the gauge registered right up to the top and no telling how much further

DEVELOPMENTS IN SHOP EQUIPMENT

LUBRICATION SYSTEM

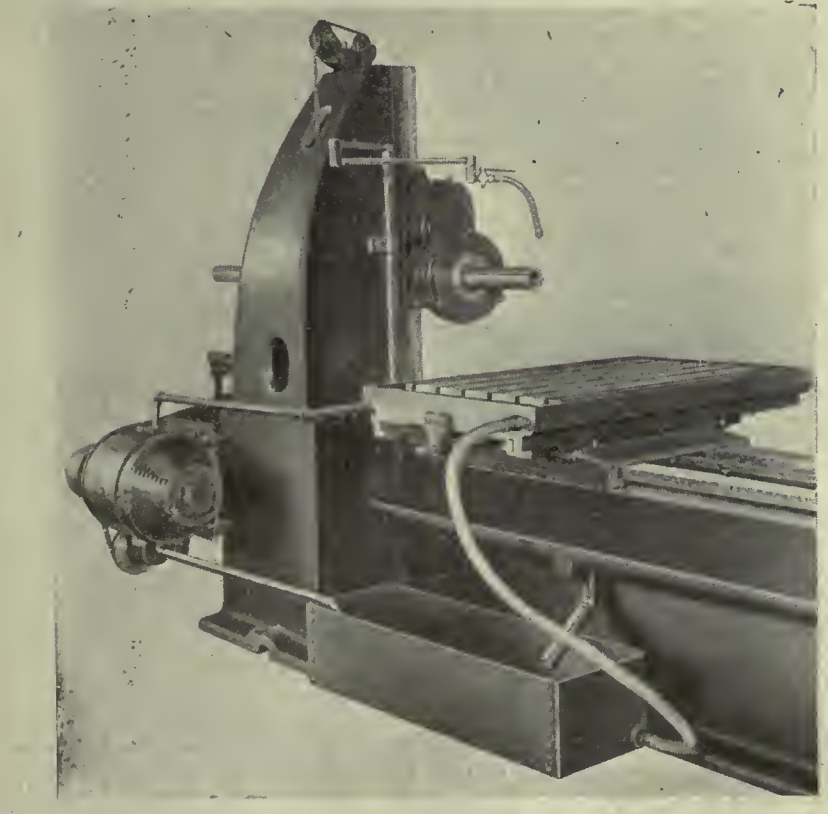
Modern experiments in cutting metal under a lubricant and coolant have led the Universal Boring Machine Co., Hudson, Mass., to provide their machines with equipment to pump and handle sufficient coolant.

As is well known the purpose of any coolant is to assist in arrying away heat from the place where the work is being done, thus keeping down the temperature of the cutting edge of the tool.

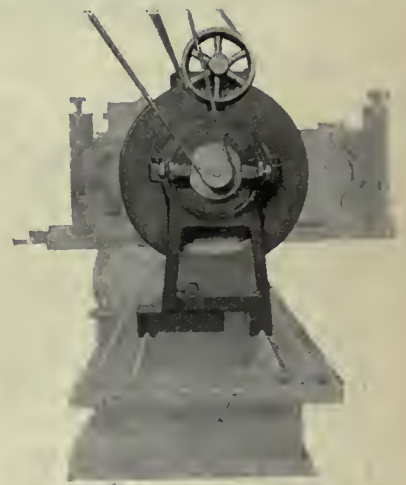
On the assumption that it is far better to use too much than too little coolant, they have equipped their machine to deliver twelve gallons a minute to the tool, if necessary. The pump used is claimed to never lose its prime. The system is said to be clog-proof, because anything that can get in can proceed through without injury to the pump, because there is no passage in the entire system smaller than the intake, which is ¾ in. The impellor pumps by centrifugal force, and any chips that can enter pass right through the system, thus avoiding the necessity of strainers.

The bed of machine has oil troughs on the front and back. These slope towards the centre. The front trough is on a higher level than the rear. The lubricant is carried by a 1¾ in. pipe from the centre of the front trough, through the bed to the centre of the rear trough and from there into the tank. The troughs project 4¾ in. and are 4 in. deep.

Between the ways on the top of the bed, the surface slopes toward the centre into a rectangular trough 16 in. long. From there the lubricant is carried into the tank. The table has oil pockets on each end and grooves in the T-slots, and delivers the lubricant toward the rear. From there it is carried by a flexible tube of ample diameter into the tank in the rear. The pump is attached to the motor bracket and is driven by belt from the motor shaft. It has a capacity of twelve gallons per minute. The lubricant is carried from the pump to the tool by piping and elbows with a flexible tube nozzle to facilitate the flow in any direction. The photograph shows clearly the arrangement. We understand that the concern will equip their machines with this lubrication system on special order.



SHOWING METHOD OF ATTACHING LUBRICANT SYSTEM.



END VIEW OF THE FIXTURE.

BORING AND GRINDING MACHINE

The Sunderland Machine Shops, Omaha, have placed on the market what is known as the Fox cylinder and boring machine. The two views shown give a good idea of this machine's general appearance. It will fit in any lathe, 14 in. to 24 in. swing, and can be used on either open head or closed cylinder blocks.

In use, the cylinder is mounted in the fixture as shown in illustration, and is so adjusted by the fixture screws and the cross-slide screw that the centre of the bore is in line with the centre of the boring head.

The boring head is equipped with an outer spindle to which the boring tool can be attached. This spindle revolves at a slow rate of speed and is driven through a large heavy-duty enclosed gear bolted to its outer surface. An overhead belt transmits power to the pinion shaft, which is equipped with tight and loose pulleys. The inner or grinding spindle rotates inside the outer boring spindle and is supported by three sets of S K F double-row self-aligning ball bearings which give it the required bearing support, thus assuring a true and free-running shaft that will not throw out, whip, or vibrate. It is claimed that a degree of exactness of 0.00025 inch can be readily obtained with this machine if desired.

Among some of the advantages claimed for it are its low cost, the fact that it can be used for boring or grinding

with equally good results, that it can be mounted or removed from the lathe in ten minutes, that changing the work from one cylinder bore to another requires only a few seconds, and that its use does not interfere with chucking work in the lathe. The capacities are:

GENERAL VIEW OF THE MACHINE IN ACTION.

Swing of spindle, 22 inches; boring and grinding capacities, 2½ inches and larger; and length of spindle, 15½ inches. The equipment includes one main spindle and operating standard, one countershaft, one cross-slide table, two adjustable work-holding brackets, one cutterhead, two grinding wheels, one diamond wheel tracer, one truing-up indicator, and two wrenches. The machine equipment, boxed for shipment, weighs approximately 500 pounds.

KEY-SEATING MACHINE

A horizontal key-seating machine is a new line being put on the market by the Hercules Manufacturing Company, of Portland, Ore. The work-holding face plate is secured to one end of the machine and may be tilted to accommodate pieces with tapered keyways. The machine cuts on the forward stroke and the cutting tool is relieved on the backward stroke by the action of wedge shaped blocks operating in the base of the bar rest. The machine is light and particularly well adapted for taking to heavy work, in place of bringing the work to the machine.

PLATE MILLING MACHINE

A plate milling machine for milling the edges of boiler plates has been placed on the market by the Marshalltown Manufacturing Company, of Marshalltown, Iowa. The operating mechanism is carried on a sliding head that operates the full length of the machine, a 5 h.p. motor being provided for driving the spindle. Both a friction slip and a quick return are provided in the feed mechanism. Ball bearing thrust is fitted to the spindle. Rollers are provided on each side of the cutters for holding down the work. Machines are made in four sizes, having a range of from 8 to 24 feet.

NEW THINGS IN MACHINE TOOLS

COMBINATION TOOLHOLDER

Maurice H. Derringer, of 3133 N. Eighth St., Philadelphia, Pa., has placed on the market a special toolholder for lathe use. One end of the bar is fitted with a yoke that may be swung to either side of the bar as desired. One side of the bar is adapted for the holding of square stock while the other is provided with a groove for the holding of round stock. The opposite end of the bar is fitted with a gooseneck that can be locked in position at any angle.

FALCON PIPE WRENCH

J. H. Williams and Company, of Brooklyn, N.Y., has added to its line a new Falcon wrench that has a wide range of application and is particularly adapted for piping installations. The jaw is of curved design with open ends, which makes it very suitable for operations on awkward fittings. The wrench is designed for one way operations. The jaw is symmetrical, so that when one side becomes dull it may be reversed, thus doubling its life. These wrenches are made in six sizes, with ranges from ½ inch to 12-inch pipe.

REVERSIBLE DRIVING CHUCK

The Gustin-Bacon Manufacturing Company, of Kansas City, Mo., are offering to the trade a reversible driving chuck, that will grip the stock when running in either direction, being adapted for use on such work where it is desired to reverse the direction of rotation. The jaws are of tool steel and it is claimed that the work is held centrally at all times. A large number of jaws are obtainable for different classes of work.

OIL AND WATER STRAINER

The Griscom-Russell Company of New York, are now making a strainer that is intended for use in the straining of lubricating, fuel or quenching oil, or in water supply lines. The body is of cast iron and the strainer is of perforated sheet steel, and when the strainer is used for oil it is lined with fine mesh wire. The strainer connections may be made to suit any desired purpose, and may be installed in units or in sets. When used in sets either one of the strainers may be cleaned without interrupting the service.

BENCH HORN PRESS

The Enterprise Machinery Company, of Chicago, Ill., have recently placed on the market a bench horn press known as the type "V." The press is intended for rapid assembly of small parts and for operation such as seaming and riveting on hollow work. The machine is of the single stop type with strokes of ¾, 1¼, and 1¾ inches. The ram has an adjustment of ½ inch. The press is 26 inches high and operates at 300 r.p.m.

DROP HAMMER

Long and Allstatter Company, of Hamilton, Ohio, are now manufacturing a new type of drop hammer. Frame adjustment is provided and a positive automatic arrangement is used to prevent the frames from loosening. Increased distance is provided between the V-guides, giving a wider range to the dies used. The weight of the anvil is approximately fifteen times that of the ram, and means are provided for recording the various heights at which the ram should be released for each set of dies, thus assuring duplicate work at different periods. The machine is made in eight sizes, ranging in size from 100 to 1,200 pounds falling weight.

LO-SWING LATHE

The Fitchburg Machine Company of Fitchburg, Mass., are now making a 4-inch Lo-swing lathe. It is of the constant speed type and both speeds and feeds are controlled by levers in the headstock. The two carriages, each carying three tools, operate on heavy V's so located that the carriages may be run past the tailstock. The feed gears in the carriages are driven by means of Oldham couples which eliminate the necessity for accurate alignment. Sliding gears are provided for the reverse feed. These lathes are made in three lengths, 60, 80 and 108 inches.

INSERTED CENTER POINTS

The Eastern Tube and Tool Company, of Brooklyn, N. Y., are introducing a new line of machine center points made of high speed steel for insertion in to the mild steel shank, which are hardened and ground, and furnished in all standard sizes and tapers.

HYDRAULIC TURRET LATHE

Albert Herbert, Limited, of Coventry, England, through their American offices, are placing on the market a special design of hydraulic turret lathe that was originated by an Italian, and intended for use by disabled men. The chuck turret and the cross slide are all operated by means of hydraulic cylinders conveniently situated. A minimum pressure of 75 lbs. is used for the operation of the machine.

Japan has another plant to its credit, that being a new one just completed for manufacturing thick steel plate. It is owned by the Imperial Steel Works at Yawata, Kyushu, and cost 4,000,000 yen.

Wanted—A Superintendent

THERE was a vacancy to be filled in an organization not many miles from Toronto. It was one of the worth-while jobs that crop up only on rare occasions.

The superintendent was leaving to go into business for himself. He had been with the firm for some years, was a good man, and his departure meant finding another good man to take his place.

There was a conference right straight off, and the president and general manager, for he held the dual position, wanted to know if any of the others present had in view the name of any other man who could be brought in to take over the work.

A number of names were suggested, but one by one they were discarded, and the only result of the meeting was to make it plain that the gathering was almost back where it started, with the possible exception of having gained the knowledge that it was no small task to find the man they wanted.

The vice-president of the company, who also held the position of secretary, at the first chance the following day, started on a new line.

He called the manager to his office and proposed the name of the foreman of the machine shop.

"But he's had no experience as superintendent," objected the manager.

"Neither had he any experience as foreman of a machine shop until he was put in that position here," was the answer.

The manager admitted that he had turned out to be a good foreman.

"Well, then," came back the vice-president, "if he made a good foreman, why not a good superintendent?"

The result was that the foreman of the machine shop, one of the company's own men, was taken in and made superintendent. He is just as good a superintendent as he was foreman.

The point is here:—Is your shop a place where you are growing foremen or superintendents, or are you dwarfing them so that they stay as machine operators and clock punchers?

How do you make a good foreman? By selecting a skilled mechanic with an honest personality, one with some leadership preferred. Very well—that is just a starting point. You must put responsibility on him—give him a chance to make good, and put that most important of all things on him, the seal of approval in the shape of increasing wages.

The average man wants to develop. It is the most natural thing in the world that he should.

If you find it necessary to start a gum-shoeing trip all over the country every time a worth-while position opens up in your organization, it's high time you turned the X-rays on the organization to find out the trouble.

Some shops grow foremen and superintendents, and some shops do not.

What kind of a crop are you growing?

Mr. Findley's Statement

THE address of Mr. Thomas Findley, of the Massey-Harris Co., before the Tariff Commission at Winnipeg, has been published in many Canadian papers as paid advertising.

It may be that it is necessary to do this in order to get his views before the public. It is a fact, though, that the same papers publish every day a tremendous amount of material that is not half as interesting nor one-quarter as instructive as the facts presented by Mr. Findley.

He reviewed the position of his company; he told of all the tinkering that had been done with the tariff on agricultural machinery; mentioned the loss the farmers were inflicting upon themselves by not housing their implements; showed that the farmer in Saskatchewan was buying his binder cheaper than the farmer south of him in North Dakota or Montana.

This paper cannot recall offhand where any man has so thoroughly laid before the public the business of his company.

It is just such frankness, and such adherence to facts that will stand up after investigation that will carry conviction.

Mr. Findley has done much to spike the guns of free trade shouters—or at least he has made it increasingly necessary for them to verify their statements before parading them before the public in print.

The Why of Time Clocks

THERE are plenty of men in shops who object to "punching the clock." Every time they shove in their ticket they do so with a grudge in every move, and there is often far more ginger put into a vigorous smash on the clock lever than in any other operation that takes place in the shop hours.

Whence come clocks and the demand for them?

Look back a bit and the thing is very plain. Men used to work long hours and the wages were low. If a man were a few minutes late, the firm lost very little. This few minutes would amount to only a few cents, and the loss could be made up or absorbed in some other way.

It is a different proposition now.

Men are working many hours a week less than they used to, and they are getting a much greater amount for the shorter work day.

This has become so marked that a manufacturer has to reckon in minutes where he used to speak and think and plan his work in hours. A man in the shop working a short day has less time in which to speed up for any time lost in the morning.

Labor unions have insisted upon the shorter day, and in self defence it becomes necessary for the employer to see to it that he gets full measure for his work-day.

MARKET DEVELOPMENTS

Trading Quieter, But Prices Remain Firm

Many of the Machine Tool Centres Report Little Inquiry, But There is No Evidence Yet that Any of the Makers Are Thinking Seriously of a Price Reduction.

THERE is not a large volume of business moving in any of the machine tool markets. None of the Canadian centres report any great buying, and the New York market says that it is quieter there now than for months past, with very little hope of recovery. Some of the Canadian dealers are inclined to blame tight money for keeping some prospective buyers out of the money, and they claim they could dispose of a number of machines were their prospects able to finance. There is a fair number of orders as it is, but they are very much scattered. Dealers in this country do not complain of the stagnation that seems to have hit the New York market.

The supply of steel is a little more liberal, but the price that must be paid is liberal in proportion. The premium mills are making the great bulk of the deliveries that are reaching this market in the way of sheets, and they are still romping off with a high figure for their material. Warehousing interests are getting more or less nervous about going in and tackling large tonnages of this stuff, fearing that the premium market might crack, and leave them with a shipment on their hands in a skidding market.

As far as machine tool dealers can interpret the situation, they cannot see any price reduction yet. Many of the firms they represent are still booked for months to come, and the orders are all of the non-cancellation variety. It is seldom that a request comes for cancellation, a healthy sign for Canadian industry.

A further revision of prices has been made in Toronto warehouse lists bringing bar iron and steel and bar mill shapes up to $5.75 per hundred pounds, a new high mark, and one not equalled in the memory of most of the steel men in Toronto.

The scrap metal market is still waiting for something to start it off on busy days again, but that something has not appeared, although some of the dealers claim that the only thing to restore the volume of trade is a lower level of prices.

NEW RATES SEEM TO BRING A QUICKER MOVEMENT OF THE CARS

Special to Canadian Machinery

MONTREAL, Que. Sept. 23.—Apparently, one good result that the increased freight rates have brought about has been the improvement that has materialized in the delivery of goods to consumers. This condition, while not pronounced, has nevertheless given encouragement to many buyers of material. A feature that has prevented a greater betterment in United States shipments of steels and other metal lines is the tendency of the railroads in Canada to keep their equipment on their own roads so as to take care of the heavy demand now being made to move the western crops. The car situation has been a sore point during the past year, but improvement has gradually been evident, and when the grain shipments have been taken care of the movement of ordinary freight will soon reach normal.

The steel situation has developed little of interest during the past week, and operations in this district are much the same as what they have been for the past several months. In some respects the reports indicate that the activity is quieter in general and that the market is taking on a weaker tone. It was thought that the increased freight rates would be followed by a combined effort on the part of the dealers to adjust prices to the new conditions, so as to take care of the extra cost of transportation. This tendency, however, has been offset somewhat by the quieter tone of business, and although some dealers are tacking on the extra freight charges to quotations, others are allowing the old prices to stand and are absorbing the additional freight charges themselves. Consumers are in the market constantly, but buying sparingly, and trading is carried on in the hand-to-mouth style that has been more or less the order of things for the past eighteen months. Dealers report that no large developments are anticipated and this gives the impression that the fall activity will be of a conservative character. Another factor is the fact that mill production at present is above the existing demand, so that supplies are gradually assuming the position when an easier market should obtain. The lesser requirements for some commodities, notably the automobile industry, has enabled the mills to devote more time to other needed lines, so that the trade may shortly see steels listed at lower figures. One naturally looks for increased costs when freight rates are advanced, but present conditions may show that the higher charges will provide the necessary means of more rapid transportation of material, with the result that the congestion at producing points will be relieved and raw materials delivered to the producer more regularly. Shipments to this district have shown gradual improvement of late.

Light Machine Demand

As a result of the curtailment that has evidently developed in the automobile industry the activity in machine tool lines has been somewhat disjointed, due to cancellations of equipment or extended delivery. This has reacted in many ways, and foundries and other metal trades have experienced a movement to a quieter period. This trend has come at a time when users of tools were contemplating the call for higher charges on equipment haulage. The de-

mand of late, however, has been easing off, so that dealers are willing to lower the quotations slightly to counteract the extra cost that would figure in the additional freight charges. While local dealers are reporting a quiet spell, the sales are a fair average for the year. Sales of heavy tools are light, but other machines and small supplies are of sufficient volume to maintain a balance of trade.

Scrap is Listless

There is little to report on the old material situation as the quiet character of the market has nothing of interest for the trade. Operators are almost entirely confined to local trading and in this respect the buying is solely for current needs and no covering is made for future requirements. Dealers are devoid of interest and transactions are carried on more on the nature of the individual sale than on market prices or conditions. Prices locally are only to be consedered in a nominal way.

PREMIUM MILLS SUPPLY TRADE

Otherwise Some Lines Would Be Very Short in the Canadian Market

TORONTO. — The trade is becoming more or less accustomed to the new freight schedules that are now in effect on the Canadian roads, at least very little is ever heard about the matter in the markets. One matter that is quite conspicuous is the scarcity of ready money, and the difficulty with which existing lines of credit are given a little elasticity in order to meet certain situations.

Some of those who are in the machine tool business seem to be quite certain that the difficulty in getting credit and financial assistance is keeping not a few buyers out of the market, and that when matters ease off a little, and there is more ready money to be had, there will be more business in their line.

"We have had men come in here," stated the manager of one Toronto house this morning, "and tell us that they have certain extensions to their plant in mind, and asking what we can do for them in the way of extending payments. The banks apparently cannot see their way clear to give them the assistance or the time they desire, and they think they can get it from the machine tool dealers, but as a matter of fact we would soon be in for a lot of trouble were we to undertake to finance things on paper that the bank would not accept or deal in. There will come a time when this business will come into the market, as we are certain these men want to make extensions, and they are not bluffing about it either."

No Price Crack Coming

Dealers generally are confident that prices as they stand now will be the prices at which machine tools will sell for some months to come. "As far as we can see there is no chance of anything happening to the price situation, and we are very certain that there will be nothing approaching a price cutting business. If such a thing were to happen it would simply mean that we would have each other's business in a couple of months at reduced prices. Most of the bookings that are on the way through now have a non-cancellation clause attached to them, and in that way there is a very small chance of anything approaching trouble coming on the trade."

The makers will need to be a great deal more keen for business before reductions will be thought of. Some of them are showing a better delivery schedule, but in many lines there is still quite a few weeks between bookings and deliveries, and this sort of thing will have to be worn down a lot more before price reduction will be a necessity.

The dealer who complains that he is not in on any big orders in the Canadian market just now need not feel hurt, as there is no big buying being done, but there is a good showing of smaller business, and it is fairly well distributed.

Small tools remain the same in price. Some of the railroad business has not been placed yet. Most of what is being purchased now is for the eastern shops.

The Steel Market

There has been a further revision of the Toronto market upward to take care of the freight rates and other costs. It now means that the base price for steel and iron bars and bar mill shapes is 5.75 per 100 pounds. This is the highest price that has been reached in the memory of some of the oldest dealers in the warehousing business here.

There is a fair arrival of sheets, but it is all from the premium mills, and on orders that were placed only a few days ago. These premium mills are out to cater to the hand-to-mouth trade. The chances are that they never get booked up over a week or so in advance, always holding themselves in readiness to turn out a rolling in very short order for a customer who is willing to pay the price for immediate delivery.

One well-known stove maker was making the rounds this morning looking for sheets. He was almost out of certain gauges, especially anything near 22 or 24, which is the size much in demand by this class of trade. He was mightily pleased to find what he wanted, although he had to pay the high price for it. With him it was simply a case of getting the material or shutting off that corner of his shop, which is particularly busy at this season.

Just how long the warehouses will keep on going into the premium market is problematical. There is always the danger of dealers waking up some fine morning to find that there is a crack in the premium market, and it is not a happy chance to have a good sized tonnage on the way when such a thing takes place. Those who watch the market closely believe that there will be a chance, but they cannot see it right away, and apparently they are willing to take a chance of getting away with premium goods for a time yet.

Boiler tubes are coming across in fairly good numbers, but the assortment is far from complete yet. There are some of the much-wanted sizes that are not to be had, particularly in the case of 3-inch, several of the houses being short of these. There is a big market in this country now for boiler tubes, and a very large tonnage could be disposed of were it possible to secure them.

There is not the volume of delivery coming from the Canadian mills that could be hoped for, as they are still working without adequate supplies of coal.

POINTS IN WEEK'S MARKETING NOTES

Reports from Pittsburgh claim that the shop facilities have improved to such an extent that they are rapidly reducing accumulation of steel in the yards there.

—

There is very little demand in the United States steel market for structural shapes, plates, and the larger size of merchant steel bars. Prices on these are not reduced, the mills holding that such a course would not bring them any new business.

—

One report from the steel mill section is that some of the mills will be forced to curtail production in November.

—

The deliveries of sheets in the Toronto market are nearly all through the independent and premium mills.

—

Some machine tool dealers believe that the tightness of money at the present time is keeping a number of buyers out of the market.

—

Any suggestion in the reduction in the prices of machinery finds little encouragement in the markets. Some firms are still many weeks behind in their deliveries.

—

There was another change made in the price of steel and iron bars and bar mill shapes in the Toronto warehouses, the face price now being $5.75 per hundred, which is a record high price.

—

The stove markets are finding it difficult to secure enough of the proper gauge of sheets to keep their plants in operation.

MILLS ARE REDUCING THE PILES STACKED AROUND THEIR PREMISES

Special to CANADIAN MACHINERY.

PITTSBURGH, Sept. 23.—In the main, the production of steel tends to increase, being helped by constantly improving rail traffic conditions, but here and there some of the smaller mills are reducing output or planning to reduce output, on account of their orders having fallen off. The larger mills, which sold farther ahead, are well supplied with orders.

While production has been increasing somewhat, shipments have been increasing still more, as the mills are able to move more of their accumulated steel. The Carnegie Steel Company is reported to have reduced its accumulation of steel by about one-third, from the top point, leaving about a third of a million tons, a trifle over half of which is in ingots and semi-finished steel.

Delivery Demands

In more than half the finished steel lines the deliveries are such that consumers are in easy position and are not pressing the mills for heavier shipments. In tin plates, wire nails and the smaller sizes of merchant steel bars there is still urgent request on the part of many buyers for heavier shipments against contracts, though there is relatively little new buying. In sheets there is considerable pressure from some consuming lines, but the deliveries on the whole are moderately good, being helped by the fact that the automobile industry has canceled some orders entirely, while on many others it has called for reduction or suspension in shipments. An extreme case is that of an automobile factory which ordered a mill to suspend shipments instantly, and raised an issue because the mill allowed a car to go forward that was already loaded and shipped two cars with material that had already been made to the buyer's specifications. The mill was, of course, far within its rights in this matter, since it is a universal policy that consents to hold up the filling of specifications. When the material has actually been produced the mill always expects the buyer to take it.

Prompt Market Quiet

While there is still some buying of prompt deliveries in certain lines the general aspect of the prompt delivery market is one of quietness. The situation results from better deliveries more than from decreased requirements, though in some cases, particularly in the automobile industry, the consumptive requirements have declined. Many buyers some months ago were following the familiar course of doubling up on purchases. Having contracted for the amount of steel required, and not receiving deliveries as rapidly as the contract called for, these buyers went out into the open market and bought additional tonnages. Now both classes of steel are coming, resulting in some cases in there being more than is needed, and in nearly all cases in a cessation of the prompt buying.

Stocks on Hand

The usual question at this time is being asked without getting an answer, how much steel the buyers have in stock. After a period of stringency in deliveries the common assumption is that buyers necessarily cannot have any stocks, yet in the past it has always developed that many of them had stocks. Buyers are in various positions, and usually the case is that the trade hears of those who are short of steel while it hears nothing about those that are well stocked. At the present time buyers are content to carry their stocks, those that have any, for while the railroad situation is greatly improved the better position may not last. Usually the peak of the load on the railroads comes in October, on account of the crop movements, and after that there are the usual dangers of winter weather slowing down the railroad movement. At this time, therefore, the buyer concludes that a stock is a good thing to have. His position may, however, change radically in the course of a month or two, when he gets near to inventory time, for he may then suddenly become desirous of having his inventory as small as possible.

Items in Light Demand

Demand is practically absent for structural shapes, plates and the larger sizes of merchant steel bars. Mills are maintaining prices on these partly because there is no business and reducing prices would not create business, partly because they can put their steel into forms that are in more request, and partly because they have contracts on books at full prices, which they desire to protect. Structural shapes are not offered at less than 3.10c. so far as can be ascertained, by any of the independents, and this is $13 a ton above the Steel Corporation price of 2.45c. Plates are now commonly quoted at 3.25c. as several independent mills will make this quotation. Some mills are asking more, but their prices are simply nominal. The mills seem to have made 3.25c a sort of dead line, below which they will not go.

Duration of Business Readjustment

That business generally is in process of readjustment is admitted on all hands. The only divergence of opinion is as to the extent of the readjustment and the length of time that will be required before markets turn more active again. Some observers think there is to be merely a shortlived lull in business activity, while in other quarters the view is that it will be more than a year hence before business is really on the up grade again. There is agreement on this point, that lessened activity is needed to bring down commodity prices and the cost of labor, measuring the latter not necessarily in wage rates per hour or per day, but rather in the amount of work done for a given sum of money. Thus the question seems to resolve itself into one of how long the present momentum of business will carry things before there can be sufficient slackening to produce this readjustment. For the steel trade, the common prediction is that the industry in general, drawing inferences from the position of both producers and consumers, has enough steam up to run it not only through this year but into next year. According to this view the steel mills are going to run, with an occasional exception, at the best rate the physical conditions permit, at least, through this year and probably into early spring. In a few quarters, however, this view is considered altogether too sanguine, and the idea is expressed that it should not be surprising if the mills should be forced to curtail production sharply in November. As to steel prices, practically the unanimous opinion is that they will stay up until after the mills have had a period of relative idleness. The mills will stubbornly resist price declines and they have made so much money that they can well afford to be independent.

Pig iron is stagnant, with prices not quotably changed.

NEW YORK TOOL TRADE VERY QUIET

Various Views Taken on What is Liable to Happen There in Near Future

NEW YORK, Sept. 23.—Some in the machine tool trade describe conditions as "the quietest in years." Both inquiries and orders are few and far between, and with some machine tool manufacturers orders in the past month or so have been entirely offset by cancellations. It is surprising how quickly the machine tool trade has altered from unexampled prosperity to uncertainty. Even those machine tool plants whose order books are in the best of condition of any have scarcely more than three or four months business ahead, and unless there should be a buying movement by the first of the year, at the latest, a majority of the plants of the United States will find themselves at that time with scarcely any business ahead. Some companies are even now caught up on orders on some lines and either are making tools for stock or have curtailed their manufacturing operations.

Despite the present uncertainty as to the future of business in the near three to six months, there are some who do not view the situation pessimistically, but on the contrary look for a resumption of buying on a fairly good scale within the next 30 or 60 days; at any rate after the presidential election. Many manufacturing plants are extremely busy, but others are running on part

time and quite a number have let men go. The industrial situation is spotty, but not alarming.

Except for an inquiry from the Standard Oil Co. of New Jersey for a few machines, there is scarcely an inquiry in the market worthy of note. There are occasional orders for single machines, but even this business in the aggregate is not large.

MONTREAL NOTES

The new factory of the L. E. Waterman Company at St. Lambert was officially opened last week, when a number of notable men from England, New Zealand, United States and Canada, were guests of the company. H. L. Symonds, chairman of the London, England, Chamber of Commerce, officiated at the opening.

—

Henry Berry, vice-president and general manager of the Canadian Asbestos Company, died last week, after an illness of several months. Mr. Berry had been associated with the asbestos industry nearly all his life and his own personal efforts in this direction had done much to widen the field of usefulness of this great Canadian mineral. Mr. Berry was 55 years of age; he leaves a widow and three sons.

—

The Grand Trunk management has appointed Mrs. E. H. Gaudion as welfare superintendent of the female clerical staff at their head offices in Montreal. Mrs. Gaudion will devote her entire time and special training to the duties of this position, the desire of the management being to make the environment of office life as healthy and happy as possible. The Welfare Superintendent will have charge of the lunch room and rest rooms and will also extend her help to the homes of girls in cases of sickness.

—

Negotiations have been finally concluded for the erection of a mammoth 1,000 room hotel in Montreal. Frank A. Dudley, president of the United Hotels Company of America, and a number of prominent commercial and industrial men of the city have formed the Mount Royal Hotel Company, Limited of Montreal, with a capital of 10 million dollars. The site secured for the new hotel is the block bordered by Peel, Burnside, Metcalfe and St. Catherine streets. It is expected that an early start will be made on the construction work. The officers of the newly organized company will be: Frank A. Dudley, president; Hon. W. J. Shaughnessy, first vice-president; and W. J. Cluff, second vice-president.

Authorization has been given for the increase of the capital stock of the Atlas Construction Company, Ltd., from the sum of $100,000 to $500,000; such increase to consist of 4,000 shares of $100 each.

PIG IRON TRADE

There is not much general buying in the pig iron market, but shipments from furnaces are being readily taken up. Where automobile plants are suspending delivery, other plants are taking the iron they refuse. The reports from Philadelphia show that furnaces are well booked up, and are offering but little material. Steel works which are not very well provided for are still clamoring for delivery, particularly of basic grade. This grade is now selling at $50 furnace. There has been no change in foundry grades.

Chicago producers are well booked ahead, but the market is by no means weak though inquiry in pig iron is slack. Requests for shipment are being made by the smelters, as few have accumulated iron beyond their present needs. There is no demand for basic iron, owing to buyers waiting for orders from the railroads before buying.

New business in Cleveland is exceedingly small, owing to a continued fall in the market. Furnace shipments are continuing, however, on a higher scale and with the exception of automobile foundries, consumers are buying. Prevailing prices were $46 to $47 for next year, $47 to $48 for this year.

Boston reports that requirements for New England consumers are covered for this year. All the principal railroads are now open. Castings are in demand and foundries busy.

The market for pig iron in New York has been good. Sales for scattered lots amounted to several thousand tons for delivery this year at established prices. New inquiry has been light. Consumers are able to procure iron more easily owing to improved transportation. Eastern Pennsylvania iron has been sold at prices ranging from $50 to $51, for 1.75 to 2.25 silicon, to $53 to $54 for 2.25 to 2.75 silicon. Some southern foundry iron is selling at $42, furnace, for delivery this year and next.

Pittsburgh market for pig iron remains dull. The prices are firm owing to the orders on hand.

Buffalo. — There appears to be very little business in the market here. Enough has gone through, however, to establish $50 as the prevailing market price for No. 2 plain foundry iron. Bookings for 1921 are very small, buyers apparently hoping for something more favorable in the way of price.

Reports are made that business is almost at a standstill at St. Louis. The western and north-western sections, however, are better — prices quoted were from $42 to $45 for 1.75 to 2.25 silicon, for prompt and future delivery.

Southern markets are inactive, but the market is considered strong. No. 2 foundry is quoted on a basis of $42.

U.S. SCRAP METAL

Pittsburgh. — The market for open-hearth grades of scrap has softened, owing to the fact that deliveries are better and also to the withdrawal of one of the large steel companies. Some of the smaller dealers who had tonnages which they were unable to move because of shortage of cars are now getting permits for immediate transportation.

Boston.—The market here is strong despite the heavy advance in freight rates, and dealers are able to place fair sized tonnages for shipment to the steel mills.

New York.—There is a fair amount of inquiry for most grades. Prices of iron and steel scrap are firm, and while a firm tone still prevails no further advances have been reported. Cast scrap continues in chief demand and is scarce.

Philadelphia.—An eastern steel maker bought several thousand tons of cast iron borings during the past week. Some borings have been sold as high as $25, the highest level for this grade in 30 years. This is attributed to the increased freight rates, and the decreased production on the part of Detroit automobile builders.

Buffalo.—Steel is in greater demand than other grades. Dealers can sell almost any tonnage of turnings and borings. Most of material going forward is on old contracts. New orders placed are for prompt delivery, there being little business for future delivery.

Cleveland.—The market for iron and steel scrap is downward. Quotations have been marked down sharply during the past week.

Cincinnati. — The iron and steel scrap market in this district is firm, with large consumers buying. Higher prices are quoted for some foundry grades.

Chicago. — Prices of iron and steel scrap have continued to decline, owing to consumers having no interest in the market and the movement of scrap being negligible.

St. Louis.—The scrap market is very uncertain. The underlying trend seems to be toward lower prices. but as yet dealers' lists do not reflect this.

Much Coal Arriving.—A Hamilton report says:—Unless something very unexpected happens, the much-talked-of coal famine this winter will not be realized, according to local railwaymen. For the last two months thousands of tons of coal have been rushed into this province, and the railways are still busy moving shipments of coal from the mines and returning empties with all possible speed. On an average of 400 cars of coal a day is cleared at Niagara Falls on the G.T.R. The T. H. & B. and C. P. R. at this point also move a large number of cars each day. The record established by the G. T. R. several weeks ago, when they moved 900 cars of coal from the border has not yet been broken.

Inspectors and Car Foremen in Session

Large Gathering at Montreal Where Many Useful Matters Were Discussed—A Large Number of Firms Were Represented at the Gathering.

THE 20th Annual Convention of the Chief Interchange Inspectors and Car Foremen's Associations of America, which was held for three days last week at the Windsor Hotel in Montreal, was one of the most successful in the history of the organization. Over 300 delegates were present from all parts of the United States and Canada. The meeting was held in the large assembly hall of the hotel, and the rear portion was devoted to the mechanical appliances exhibit. In addition to the general business sessions several papers were presented followed by a considerable discussion. These papers included:—Lubrication of Freight and Passenger Equipment by M. J. O'Connor, special lubrication inspector of the N.Y.C.R. R.; Freight Claim Prevention, by T. A. Ward, chief clerk freight claim department of the N. Y. C. R. R.; Examination of Car Inspectors, by E. H. Hall, superintendent of car department of the Chicago Great Western R. R.; Best Means of Repairing Cars in Train Yard, by O. E. Sitterly, general car inspector of the Penn. R.R. The closing session was concluded with a considerable display of international amenities, when the majority of the members, being Americans, spoke of the freedom and hospitality they had enjoyed in Canada, and the Canadians replied with similar courtesies. The following officers were elected for the ensuing year:—President, Edward Pendleton, general car foreman, Chicago and Alton Ry., Peoria, Ill.; First Vice-President, A. Armstrong, chief joint car interchange inspector, Atlanta, Georgia; Second Vice-President, W. F. Westfall, special inspector of the New York Central Ry., Cleveland, Ohio; Secretary-Treasurer, W. R. Elliott, general car foreman, St. Louis, Mo., terminals. The following supply firms were represented:—American Brake and Shoe and Foundry Company, Chicago; Steel Foundries, Chicago; Bettendorf Company, Bettendorf, Ia.; Boss Lock Nut Company, of Canada, Limited, Montreal; Bradford Draft Gear Company, Chicago; Buckeye Steel Casting Company, Chicago; Camel Company, Chicago; Canada Grip Nut Company, Montreal; Canadian Car and Foundry Company, Montreal; Canadian Gold Car Heating Company, of New York; Canadian Johns-Manville Company, of Montreal; Canuck Supply Company, of Montreal; Chicago-Cleveland Car Roofing Company, of Chicago; Chicago Railway Equipment Company, of Chicago; Columbia Nut and Bolt Company, of Bridgeport, Conn.; Paul Dickinson Inc., of Chicago; Duff Manufacturing Company, of Pittsburg, Pa.; Galena-Signal Oil Company, of Canada, Montreal; Griffin Wheel Company, of Chicago; Holden Company, of Montreal; Independent Pneumatic Tool Company, of Montreal; Imperial Appliance Company, of Chicago; Imperial Belting Company, of Chicago; Liberty Tool Company, of Baltimore; Mahr Manufacturing Co., of Minneapolis; McCord and Company, of Chicago; W. H. Miner, of Chicago; National Malleable Castings, of Cleveland, Ohio; A. O. Norton, of Boston; Okweld Railway Service Company, of Chicago; Pyrene Manufacturing Company, of Montreal; Railway Review, of Chicago; Robinson Connector Company, of New York; Union Draft Gear Company, of Chicago; Westinghouse Air Brake Company, of Wilmerding, Pa.

The following is a list of those registered at the meeting of Chief Interchange Car Inspectors' and Car Foremen's Association:—

STEEL & IRON PRODUCTS OF EVERY DESCRIPTION

THE STEEL COMPANY OF CANADA LIMITED

HAMILTON **MONTREAL**

If interested tear out this page and place with letters to be be answered.

TRADE CAN BEST BE DEVELOPED APART FROM GOVERNMENT OFFICES

MR. LLOYD HARRIS, of Brantford, brought forward at the Congress of Chambers of Commerce of the British Empire one of the most plausible suggestions offered for the development of trade within the Empire, and the better understanding of the problems of all sections.

Mr. Harris' chief complaint is with the appointees of the various governments having to do with affairs of business, which, he claims, they do not understand, having had no practical training, and being bound around with conditions that keep them from developing.

After the signing of the armistice Mr. Harris was in London, England, for some months, as head of the Canadian Trade Mission there, and he had a splendid opportunity to see where the trouble was coming from in the development of more trade between the various parts of the British Empire. Mr. Harris cannot reconcile the idea of more trade and leaving the government trade organization as it is at present.

"The resources of the British Empire need co-ordination," stated Mr. Harris. "A government is not greater than public opinion, and there are times when it must be forced. A gathering such as this (the Chambers of Commerce) should have men with the vision and the knowledge to develop Empire trade as it should be developed."

Mr. Harris goes further. He believes that the body to take care of this work should be known as an Empire Trade Council, to be composed of three representatives from each outlying part of the Empire, the British Government also to appoint members. This should form a permanent trade council in London. The appointments to that body should not be made for political purposes. Those receiving the appointments should not be paid members. The idea of Mr. Harris is that there are enough men in the country who would tackle such a proposition with the sole idea of being able in this way to render some service to the country, and to bring the outlying parts of the Empire closer together. The appointments would be made for a term of three years, with new men coming in at intervals before all the older members dropped out, in this way carrying out the continuity of the programme.

The speaker was particularly plain in making the meaning clear, that on no account should the carrying out of such a scheme be left in the hands of any government officials.

FIRMS WANT TO ESTABLISH TRADE RELATIONS WITH CANADA

INFORMATION regarding the following lines can be obtained by communicating with this paper and mentioning key numbers.

1830. Engineers' and Shipbuilders' Supplies.—Firm in Scotland desire to receive catalogues and quotations from Canadian firms who are able to export anything of interest to the engineers', shipbuilders' and allied trades.

1831. Motor Trucks.—A firm of manufacturers' representatives of reliability desires to secure the agency for Canadian motor trucks—from three to five tons.

1832. Motor Cars.—A firm of commission merchants in Barbados would like to secure the agency for a Canadian motor car in Barbados, should be a five seater with all the latest improvements.

1852. Wire Rods. — A London firm wishes to hear from Canadian manufacturers of wire rods who can offer supplies for export.

1853. Nails. — A firm of travelling agents with branch offices in Jamaica, Demerara and Barbados desire to obtain a Canadian connection for nails and other small hardware.

1854. Steel Products. — Established trading corporation, with head office in Chicago, and branches throughout the world, ask to be placed in touch with Canadian manufacturers of iron and steel products, particularly structural iron, steel plates, pipes and pipe fittings of all kinds.

1855. Wire Rods.—Large ironworks in Scotland would be glad to receive quotations from Canadian producers who are in a position to export. The immediate requirements of this company are filled, owing to the arrival of a recent shipment from Canada, but they are regularly in the market.

1856. A Buenos Aires firm of general importers is interested in receiving quotations, c.i.f. for black, galvanized, oval high tension and barbed wire.

1857. A Buenos Aires firm of general importers is interested in receiving quotations, c.i.f. for iron and steel bars, beams, galvanized sheets and black sheets.

1858. A Buenos Aires firm of general importers is interested in receiving quotations, c.i.f. for tin plate.

1869. Brake-Shoes.—A Newfoundland commission agent, long in a position of trust with an important firm, wishes to be placed in communication with Canadian manufacturers of brake-shoes for trucks and sleds.

1588.—Machinery. A firm in Roumania desires to receive quotations and other particulars from Canadian firms in a position to export all kinds of electrical machines.

Annual Meeting.—The annual meeting of the shareholders of Canadian Locomotive Co., Ltd., was held in the general offices of the company, at Kingston, when a by-law providing for the adding of two directors was passed and the following board of directors elected: Aemilius Jarvis, Robert Hobson, Warren Y. Soper, John L. Whiting, K.C., James Carruthers, M. J. Haney, F. G. Wallace. At a subsequent meeting of the board of directors the executive officers for the coming year were appointed:—F. G. Wallace, president; Aemilius Jarvis chairman of the board; J. H. Birkett, treasurer; William Harty, Jr., and William Casey, were elected to the board and Mr. Casey appointed a vice-president and Mr. Harty secretary. The financial showing of the company for the past year is most gratifying, regardless of the fact that the works were closed during the first three months of the company's financial year owing to strikes. The company at the present time is working to full capacity with sufficient orders on hand to run it for several months.

Mr. J. H. Davey, who has been connected with the Brown & Sharpe Mfg. Co., of Providence, R.I., for about 25 years, has taken up the work of representing that firm in Canada. Mr. Davey has been in Glasgow as the Brown & Sharpe representative previous to coming here. He is now working with the Canadian Fairbanks-Morse Co., the sales representative of the Brown & Sharpe lines, and all sales will be made through this company as heretofore.

TRADE GOSSIP

New Catholic Union.—The National Catholic Union has established a new local in the plant of the Canadian Car & Foundry Company, Limited. According to an announcement made by Gerard Tremblay, General Secretary of the Montreal National Catholic Union, this new body is the result of the recent strike, which was followed by a shutdown of the company's plants. He stated that men, finding the company obdurate, appealed to Abbe Hebert, head of the National Union of Catholic Workers, to use his influence to bring about a termination of the trouble, with the ultimate result that the company reopened its plants. Abbe Hebert stated that the new union comprised several hundred men.

Secured Contracts.—The MacKinnon Steel Co., Ltd., Sherbrooke, Que., have contracts for the steel for Royal Bank of Canada, Bridgewater, N.S.; general contractor, Russel & McAuley, Halifax, N.S.; steel for News Boiler House Extension, Grinder Room, Sulphite Mill Boiler House, Brompton Pulp and Paper Co., East Angus, Que.; steel superstructure for bridge, 55 feet clear space, over River Pointe du Joui L'Assomption municipality at the site known as Point Jourdain, L'Assomption, Que.; general contractor, Alex. Venne, L'Assomption, Que.; steel for Wagon Shed for Imperial Oil Co., Halifax; general contractor, McDonald Construction Co., Halifax, N.S.; steel superstructure, 65 feet clear space bridge to be erected across outlet of Brome Lake, at Fulford, Que.; general contractor, C. J. Dryden Co., Ltd., Montreal, Que.; steel work for highway bridge, 60 feet long, in two spans, with 25 feet roadway and 5 feet sidewalk for City of Granby; steel for Royal Bank Lennoxville, Que.; general contractors, Newton Dakin Construction Co., Sherbrooke, Que.; steel for post office, Yarmouth, N.S.; Russel & MacAulay, general contractors, Halifax, N.S.; steel for store for L. WILLIAM CASEY JOINS THE BOARD

Vice-President and Manager of the Canadian Locomotive Plant Started There as Office Boy

William Casey was this week elected to the Board of Directors of the Canadian Locomotive Co., Kingston, and also appointed one of the vice-presidents.

WILLIAM CASEY

His promotion with this company has been a fine illustration of the possibilities of mechanical training and initiative.

He is a Kingston boy, being born there in October of 1887, so at present he is still a young man of 33. After completing his schooling he entered the employ of the Canadian Locomotive Co. as office boy. Leaving there he went to the machine shop where he served an apprenticeship, afterwards going to the drafting room. In 1907 came his first important promotion, when Mr. Casey was made machine shop foreman, remaining there until 1912 when he returned to the office to take charge of piece work and estimating. In 1914 he was made assistant to the vice-president and general manager (A. W. Wheatley) and following the latter's resignation early in 1916, Mr. Casey was appointed manager.

SIGNS OF PROGRESS

H. L. Hewson plans erection of cloth-weaving mill at cost of $50,000, at Amherst, N.S.

An extension of 126 by 85 feet, one storey high, will be made to the Kindel Bed Co., Stratford, Ont.

Buildings to the value of over one and three-quarter million dollars have been undertaken in Ottawa this year up to the end of August.

Building permits in Moose Jaw for the eight months of this year show an increase of almost a million dollars over the same period of 1919.

William Newlands and Son are architects for a first-class, modern hotel, costing $450,000 to be built at Kingston, Ont.

The Acme Sash and Door Co., Ltd., Winnipeg, have been awarded the mill work contract for a store costing $150,000 for Ramsay's, Ltd., Dauphin, Man.

Contracts have been awarded by the Technical School Commissioners, Hull, Que. The Dominion Bridge Co. secured the iron, and D. O. La Violette the stone work.

L. A. Amos, architect, 78 Crescent Street, Montreal, is preparing plans for a match factory to be erected in Quebec for Maguire, Paterson and Palmer, Ltd.

One and a half million dollars is to be expended on reconstructing the abattoir of the Pat Burns Co., Regina, Sask. The building will be of brick and concrete.

The value of building permits issued in Vancouver, B. C., the first eight months of the year is almost double the value of the permits issued during the same period of last year.

A motor truck industry, with head office in Indiana, will erect a Canadian plant at London, Ont. The incorporation of the Canadian company with a capitalization of approximately $5,000,000 is now being negotiated.

The general contract for erecting a hotel costing $1,000,000 for Benson-Hines Co., London Chambers of Commerce, has been awarded to Geo. A. Fuller Co., Ltd., 285 Beaver Hall Hill, Montreal.

Colthurst, Trace and Nichols, architects, of Windsor, are preparing plans for the construction of a huge cold storage plant, of reinforced concrete, three storeys in height. Windsor, Detroit, London and Toronto capital is behind the scheme, and construction is expected to start in the spring.

What the Manager Said :

"You'll have to get that order out by the 15th if you work the men overtime," said the manager to the machine shop superintendent. It's promised, and this firm has built up its business by keeping its promises. If your drills are not boring holes fast enough put a rush order through for some Morrow High Speed Forged Drills."

Morrow drills will bore more holes in a given time without regrinding than any other drills. They're harder, they're tougher, they're stronger. They save time, trouble and worry.

Test them. A competitive test in your own shop will prove it.

H. W. Welsh, former manager in Sherbrooke, Que., for the E. and T. Fairbanks Co., Limited, and latterly manager of the scale department of the Canadian Fairbanks-Morse Co., Montreal, Que., has joined the organization of the MacKinnon Steel Co., Limited, Sherbrooke, as manager and has already assumed his duties.

WOULD BE FOREMAN

Continued from page 290

it would have gone if it had been of greater capacity. We had all the tuyere doors open and then had iron clean to the top of the stack and coming down like rain in the yard, but we got there just the same. Next day the pulleys were replaced as they were in the beginning. After we got the castings out and found that they were good, the manager came to me and explained that he was well satisfied, but that it would now be necessary to get to work and make some money out of the place, so he proceeded to start operations on this money-making plan of his. Not interfering with me or my work he pointed at one corner of the shop and said: "We will call this No. 1 floor,—Alex. you take this." Next, he says: "This will be No. 2,—Herbert you take this." And so he numbered off each floor and put a man on each of them until the men were used up. After this he turned to me and informed me that he had engaged a core-maker, who had not yet arrived, but that in the meantime I was to make what cores were required, after which I was to mold some things which he had laid out for me. On the fourth day he came to me and told me that he would be out of town for a while but that I should mold some plow shares for which he showed me the patterns and gave me to understand that they would have to be cast with the face down. I suggested that there would have to be some getting ready done first, to which suggestion he replied in a very stern voice that there would be no more getting ready, but that getting the work out would be the only consideration. He then left me and I have never seen him since.

I wended my way back to Brantford that night and wrote to him advising him that we had parted company and that on pay day I would draw on them at the bank for my money. To this I received a rather waspy reply from the manager who seemed to be put out at my not liking his methods. True to my promise I drew on them at the bank but my draft was neither paid nor returned for over a week, when I learned that the directors had held a meeting and accepted my resignation and also asked the manager for his, so that they could both be accepted at the same time. This was done and we were both paid off—two birds killed with one stone—leaving two vacancies to be filled. Thus ended my first experience as a foundry foreman.

SOME OF THE THINGS TO BE FOUND IN THE ADVERTISING PAGES OF THIS ISSUE OF CANADIAN MACHINERY

How it is that some tool rooms cannot compete with others owing to lack of full equipment.

How it is cheaper and more satisfactory to take the machine to the job rather than the job to the machine.

Where it is possible to secure expert instruction in the care and use of grinding wheels.

Some advice to purchasers in regard to anticipating their requirements some distance ahead, owing to the shortage of raw material.

Where you can get a copy of a wrench book.

Why it is that a well made file will withstand friction and chemical reaction.

How one make of tool does in a short time work that formerly took hours.

Why it is advisable to have the clutch built for a particular purpose.

How one firm has solved the problem of making uniform abrasives.

How a well known article is only now coming onto the market since the war.

The difference between a solid tap and an adjustable one.

How the automatic milling machine is always working on the cutting surface.

How a small lathe will do work for which a heavier machine is often used.

Where to get a welding engineer to make an inspection of your plant free of cost.

How it is that a certain lathe will use less power and is faster in turning out certain classes of work.

The firm who claims that its experts are always ready to work out your problems.

Where the small shop operating on electrical power can get its compressed air.

One firm claims that it wants users to drive their machines hard.

How one miller attends to the straddle milling of "Spider" arms.

How a Canadian firm has a chain of stations to insure service from coast to coast.

WELDING BOILER SHELLS

Continued from page 289

ment, and carried out everything in connection with the welding, etc.

The extent of the new metal forming the weld between the sludge-hole and the front end-plate was approximately 21 inches in length circumferentially round the shell; 3 inches in width and ½ inch in thickness (average), the hole through the plate being completely filled up. The total cost of repairing the boiler by means of electric welding was £54. Although this may appear at first sight a large amount for a small repair yet much time was saved by adopting this means of making up the original wasted plate instead of fitting a new part altogether. Further, with regard to the tensile strength of an electrically-welded joint, this may be as much as 95 per cent. of that of the original unwelded metal, the average strength being frequently from 80 to 90 per cent.

Owen Sound.—Work will be started almost immediately upon the new dock on the east side of the Owen Sound harbor. It was authorized about a year ago, and an appropriation of $89,700 has been made for it. It will be of concrete, and will be nearly 1,000 feet long. The contract has been let to a Peterborough firm, and work should start at once. When completed all the water front owned by the Government will have concrete dockage.

DOMINION CHUCKS

STEEL OR CAST-IRON BODY
BUILT FOR HEAVY DUTY

All Screws Are Reversible

SCREWS are made of the best grade steel. Both ends are broached and are heat treated after machining. They are reversible, so that either end may be used, are large enough in diameter to stand the torsional strains applied by operator when setting up his work. They are made to give the best service—and may be depended upon to stand up under the hardest usage.

Blind Workers Prove *Efficient*

Cleveland Shops Have Opened Their Plants to the Blind and Sixty-nine Operations Are Successfully Accomplished by These Sightless Workers

By EVA B. PALMER*

"WE have in our employ a totally blind man who has been with us since Sept. 23, 1918, assembling compensator switches. This work is being done on piece work, and the fact that he is making his rate is proof positive that he is very efficient at this work. It is, I believe, a very severe test for a blind man. The fact that his work is perfect and that his speed is high enough so that he makes out on a piece work rate, which is the same as the rate for a man with all his faculties, is pretty good proof of the fact that he has been able to master a difficult job very satisfactorily. He also is a universal favorite, and I believe, is respected and loved more than any other man in the factory."

The above statement, signed by J. F. Lincoln, vice-president of the Lincoln Electric Co., is an indication of the value placed upon blind workmen by many Cleveland employers. This city was among the first in the country to see the possibilities in industry for blind artisans, and a start was made in February, 1913, when the Society for the Blind placed one man in the Lake Erie Bolt & Nut Co. He did hand nutting, and his pay ranged from 80c to $1.25 a day. He remained two years and left of his own accord, having given entire satisfaction.

The movement progressed slowly until war-time conditions created a shortage of labor, and since then many openings have been secured. To-day there are 81 blind men and women working in 40 different factories, and each placement makes the next one easier. The employer finds himself supplied with a dependable worker, for the blind man realizes that chances for him are not numerous, while the man without sight declares that he would far rather have a *man's* job than a blind man's job. The time-worn trades of chair caning, broom making and carpet weaving are still useful, but to the man who asks no odds of the world because of his affliction a regular man-size job is preferred.

The electrical field has so far revealed more practicable operations than any other, but the automobile industry, with its necessary machine shops, will undoubtedly take the lead in time, especially since machine operations have been proven feasible for blind workmen.

Nutting bolts is still being done in several shops, and W. B. Alexander, general superintendent of the National Screw & Tack Co., has this to say: "We have employed as many as ten blind men at a time, and now have very close to that number. They are employed in nutting bolts by machinery and hand, and we are well pleased with their work and production. I might also state that they are very prompt and lose very little time. During the winter months we had five of our blind employees form an orchestra, composed of piano, drum, violin and two saxaphones, for the benefit of our office help. It was very enjoyable, and furnished good music."

Regarding Accidents

Three questions are nearly always raised when the matter of employing blind labor is brought to a concern for the first time. One is the danger of accident. A large percentage of Cleveland factories carry State insurance, but many insuring with private companies are interested to experiment with blind workers. In 1919 the following modification was made in the Ohio law: "No agreement by an employee to waive his

*Executive Secretary Cleveland Society for the Blind.

rights to compensation under this act shall be valid, except that an employee who is blind may waive the compensation that may become due him for injury or disability in cases where such injury or disability may be directly caused by or due to his blindness. The Industrial Commission of Ohio may adopt and enforce rules governing the employment of such persons and the inspection of their places of employment."

It is interesting to note that only two concerns employing blind workers have availed themselves of this opportunity to escape paying compensation for possible injury. The blind man is easily the most careful in the entire plant, as loss of sight has doubled his caution, and as a result there have been no accidents so far. As employers become educated to consider a man according to what he has left rather than by what he has lost, people with handicaps will not find it so difficult to obtain work.

The second query raised is the one as to production. The person having the responsibility of fitting the blind man into his job must not only be familiar with labor conditions, but must know blindness, its splendid possibilities as well as its painful limitations. When the blind man's production is up to normal it is because most careful selection has been made, first of the job for the man and then of the man for the job. A general error of the uninformed public is to consider that blind people have traits in common, owing to a common handicap. When the employer realizes that their abilities are as varied as possible, and when he has been shown that lack of sight is no hindrance on certain operations, he is willing to try one worker after another until the right person is found. Much of the success of the Cleveland work is due to the skill and personality of the young demonstrator who is seen at work in one of the accompanying illustrations. He went blind in January, 1919, and had no factory experience whatever before losing his sight. He is thus able to meet every objection on the part of employers, as he has learned the use of tools since becoming blind and goes everywhere alone. He tried out 150 operations in 31 Cleveland factories during a period of three months, and proved nearly all of them practicable. In many instances he exceeded the average speed for sighted workers. This is not exceptional, as in several cases blind men are maintaining a higher speed rate than seeing people on the same jobs. In one large plant a blind man arranging carbon brushes on trays does almost twice as much as any one else, and is paid accordingly. In the same factory a blind man does all the work formerly performed by two sighted girls with perfect vision.

In each instance the blind worker conforms to the rules of the shop. If piece work is the rule, he receives the same rate as the other workers, while if day work is the rule he is paid in proportion to his production and receives his bonus if such is given to others in his shop.

E. G. Greene, superintendent of the Ferry Cap & Set Screw Co., made the following statement which shows the production of the blind men in his shop:

"In regard to the two blind men employed at our factory I will say that they have proved very satisfactory in every way. They are running drill presses and produce as much work as those who can see."

What About Transportation?

The third question raised is as to transportation. "But how in the world will he get here?" asks the skeptical employer. Here again the skill of the placement agent must be shown. Every effort is made to place the workers in shops accessible from their homes, and while most of the blind men and some of the women go to and from work alone, in some instances this is impracticable. There are several ways of handling this difficulty. Sometimes another member of the family is placed in the same shop, or search is made throughout the factory for an employee who lives near the blind person's home and can act as guide. In several cases the entire family has been moved near the factory.

The placement of blind women in Cleveland factories was undertaken at their own earnest request. Good news travels fast and the girls learned with

DRILLING OIL HOLES FOR SPRING BOLTS ON SINGLE SPINDLE DRILL PRESSES AT THE FERRY CAP & SET SCREW COMPANY.

STACKING COMMUTATORS AT PLANT OF RELIANCE ELECTRIC ENGINEERING CO.

astonishment of the high wages being earned by the blind men. Some of the operations now being done by women are: Counting by weight on balanced scales, taping small coils, assembling small parts of electrical apparatus and of sewing machines, running single spindle drill presses on small work, foiling mints, packing candy, stacking commutators and small laminations, setting up cartons and wrapping butter blocks.

The list given at the end of this article shows the large variety of operations which have been found entirely practicable for both blind men and women. Contrary to the expectation of many employers, the impression made by the blind worker on his fellow employees is good and one superintendent stated that the standard of promptness and also of neatness had been raised throughout the entire department as "Gus" was always on time, clean shaven and smiling. Gus is now earning $40 a week.

A good friend of the Society for the Blind, in its efforts to provide every employable blind person with a well-paid job, is C. L. Collens, president of the Reliance Electric & Engineering Co. He has promoted the undertaking among Cleveland electrical concerns and writes the following letter. "I am very glad to comment on the work of the blind employee in our plant. He is employed on the operation of stacking commutator segments, and we can speak very favorably of his accuracy and speed in this work. One noticeable feature is the steadiness with which he applies himself to his work, as there is no tendency to be distracted or interested by other work going on around him in the plant." The blind have long been an object of charity—and injustice. The new movement demands that the community do for the blind what it does for the seeing: judge each individual according to his merits and give him a fair chance to make good.

Operations Successfully Performed by Cleveland Blind

Arranging carbon brushes on trays.
Assembling:
- Ball-bearing cups for Ford cars.
- Chimneys for oil stoves.
- Compensator switches.
- Control levers.
- Controller slates.
- Door bell transformers.
- Drive flanges and shafts.
- Generators.
- Grease cups.
- Ground wire telephone clamps.
- Hot air boxes.
- Junction boxes.
- Kelly handle bars.
- Locks.
- Pittman rods.
- Plug, nut and bolt in oiler.
- Radiator parts.
- Steering gear.
- Tension studs and shuttles for sewing machines.
- Tools.
- Trolleys for electric cranes.
- Vacuum cleaner parts.
- Vibrator spark coils.
- Vacuum gas tanks.
- Wick raisers for oil stoves.
- Wire rope clamps.

Bench Work:
- Cleaning castings.
- Cleaning fire brick.
- Clamping wicks in metal rings.
- Counting by weight.
- Creasing boxes.
- Cutting and skinning cables.

Etching electric light bulbs.
Foiling mints.
Inspecting separators in storage battery cells.
Making hand-woven hats.
Nutting bolts by hand and machine.
Operating:
- Broaching machine.
- Centering and counter-sinking machine.
- Drill press.
- Grinding machine.
- Lathe for facing brake hubs.
- Milling machine, power and hand.
- Nut facing machine.
- Polishing machine.
- Porter-Cable lathe.
- Punch press.
- Single-spindle and multiple-spindle drill presses.
- Spot welding machine.
- Stamping machine.
- Tapping machine.

Honor Memory of the Late Hugh McCulloch, Sr.

Nurses' Home Opened at Galt—As a Memorial to Founder of One of the City's Best Industries—Building Complete and Furnished Throughout is Presented to the City.

As a memorial to the late Hugh McCulloch, Sr., one of the founders of the Goldie-McCulloch industry in Galt, a splendid nurses' home has been opened and presented to the city by Mr. R. O. McCulloch, one of the donors. The opening of the home, which is complete in every detail as to furnishings and equipment, was a notable occasion, being presided over by His Honor Lieutenant-Governor Clarke. Fitting reference was made to the career of the late Hugh McCulloch, and Mr. R. O. McCulloch in making the presentation gave some interesting facts in connection with the McCulloch family, and also a history of the steps leading up to the decision made by himself and Mrs. Shearson to erect a nurses' home, Mrs. Hugh McCulloch joining in the undertaking by furnishing the building throughout.

"My revered father," said Mr. R. O. McCulloch, "the late Hugh McCulloch, came to Canada from Scotland in 1850, arriving in Galt on August 24th of that year. With the exception of a few months spent in the neighboring village of Ayr, from which place he returned to Galt in 1851, his whole life until his death in 1910 was spent in this community. From 1851 until 1859 he was in the employ of James Crombie. In that year the firm of Goldie & McCulloch came into existence, when the late John Goldie and my father purchased their employer's business. In 1891 the present company was organized, and my father became its first president, which position he occupied until his death in 1910.

The Late HUGH McCULLOCH, Sr.,

To whose memory the new Nurses' Home was erected. He located in Galt in 1851, and in 1859, with the late John Goldie, purchased the Cromble foundry, establishing the firm of Goldie & McCulloch Co. The late Mr. McCulloch passed away on August 24, 1910.

"My late brother, my sister, Mrs. Charles A. Shearson, and I desired to erect a suitable memorial in affectionate remembrance of my father, and many plans and ideas were suggested and discussed, but no definite conclusion had been arrived at when the war broke out. Further consideration of the matter was, of course, postponed, and then my brother became very ill, and after a long illness died in 1917. When the war ended in 1918 the question was again taken up, and my sister-in-law wished to join with us in memory of her late husband. Different plans were canvassed, but none satisfied us until the needs of the hospital were brought to our attention. The appeal of physical suffering makes the strongest appeal to our common humanity. Hospitals were established to alleviate suffering and heal the sick; and trained nurses are the most necessary part of the equipment of a modern hospital. We learned that the accommodation for the nurses was entirely inadequate, and that consequently they were compelled to live in part of the main hospital. Everywhere there was expansion; increasing numbers of patients and more nurses required, but no accommodation for them. A residence or home for nurses appealed to us as the greatest need in the community, and we felt it would commend itself greatly to my father and brother, as they were both much interested in the hospital."

A Worthy Example

His Honor Lieut.-Governor Clarke, in opening the home, said in part:

"Mr. McCulloch was in more than one sense a real pioneer. He left his native Scotland before the old sailing vessels had been superseded by the steamer, and his passage was a long and rough one, not fewer than seventeen passengers dying during the voyage, which took about seven weeks to complete. He came, like many another pioneer in those days, specially well equipped for a successful career in Canada, which was then at the very beginning of its industrial history. He settled in Galt as far back as 1851, and with the late Mr. John Goldie gradually and surely developed the business associated with their names and known, not only throughout Canada and the United States, but in the Old Country as well. We are sometimes apt to forget the underlying principles on which national life is founded, but we have only to think a little—to look a little below the surface—in order to realize that without a well-developed, healthy and expanding industrial interest, no country can long stand, nor can the amenities of civilized life be enjoyed by its people. Therefore, it may be well to-day to think of the immense debt we owe to the contribution which the little parish of Sorn, Ayrshire, Scotland, made to Canada, when in 1850 it sent one of its sons in the person of Hugh McCulloch, a well-educated, robust and enterprising young man, then only twenty-four years of age, to this country. He very soon found his opportunity and in conjunction with Mr. Goldie, as I have said, organized the business which shares his name. The expansion of that business meant much to Galt, and beyond Galt it meant much to the Dominion, for the products of its industry not only furnished a needy market with the goods required but gave high-class, skilled labor a continually widening field. I mention this side of Mr. McCulloch's service to the country because I believe that a career such as his in this respect ought to be held in the highest esteem. An upright, honorable man, conducting business with enterprise and conscientious integrity is one of the greatest possible assets any country can have and certainly Mr. McCulloch was such a man. . . .

"One word more, I think, ought to

MR. R. O. McCULLOCH,

One of the donors of the Nurses' Home, erected to the memory of his father, who made the formal presentation of the building to the Galt Hospital Trust.

The beautiful Hugh McCulloch Memorial Nurses' Home, officially opened by His Honor, Mr. Lionel Clarke, Lieutenant-Governor of Ontario, and formally presented to the Hospital Trust by Mr. R. O. McCulloch, one of the donors. This view of the building is taken from the east side and shows some of the stalwart pines that surround it. —Photos courtesy Galt "Reporter."

be said and it is this: In erecting this home by Mrs. Shearson and Mr. McCulloch and in the furnishing of it so admirably by Mrs. Hugh McCulloch, this family has set an example to others in Galt and in other places, which would be for the public welfare were it followed, and I am sure that not only would the public welfare be advanced, but the givers themselves would have much joy in their gifts. The privilege of giving—of doing good—is one of which we can all, more or less, avail ourselves in our several ways, but those who exemplify their benevolence in such a way as we witness here to-day are specially fortunate and are to be envied in having afforded to them an opportunity to gratify the heartfelt desires with which they are so worthily inspired."

PLAY SAFE

During the week of October 10th to 16th, the Ontario Safety League will ask the public in Ontario to play safe. It will be known as Safety Week, and during this time an intensive drive will be made against accidents.

Similar large scale campaigns have been held in other cities and have been a notable success. The "Safety Week" held in St. Louis in the autumn of 1918 is the most conspiuous example, as fatal accidents in the corresponding week in 1917 were 24 and in "Safety Week" there was one fatality. Cleveland cut its fatalities in its "Week" last year from 15 in the same week of the previous year to 6 in "Safety Week." Pittsburgh cut its fatalities from 28 to 16. These facts are vital and experience has shown that the good effects of the safety propaganda have been continued month by month ever since. Similar intensive drives against accidents have been a success in industry and on the railroads, and the League looks forward with confidence to success.

During Safety Week, the various committees plan to teach accident and fire prevention to men, women and children in a spectacular educational campaign in which various forms of publicity will be used. The public will be reached by means of posters, bulletins, bill boards, street-car cards, letters, advertisements, meetings and safety shows and given a liberal education in Safety. The Safety Week idea has been approved by big industrial managers, by boards of trade, chambers of commerce, Canadian Manufacturers' Association, Toronto District Labor Council, Ontario Motor League, fire departments, police departments, boards of education, Empire Club, Rotary Club, Kiwanis Clubs, Canadian Clubs, and others.

Subcommittees of the League will cover such subjects as : Publicity, bulletins, motion pictures, schools for industrial safety, statistics, boy scouts, women, traffic, schools and colleges, etc., etc. The various days of the week have been specially designated—Safety Sunday, with special sermons in the churches; Monday is careful day for motorists; Tuesday will be careful day for street car men; Wednesday is set aside for school safety; Thursday will be at home day for safety; Friday is to be called careful day for pedestrians; and the slogan for Saturday will be "Safety for All, All for Safety."

To protect aluminum and aluminum alloys from corrosion, a German inventor has tried the experiment of browning the metal electrolytically. The aluminum is suspended in an electrolyte consisting of a sulphur compound of molybdenum, and zinc is used for the anode. The cell is maintained at a temperature of 60 deg. to 65 deg. Cent. The aluminum is soon covered with a dark brown coating. The metal may be bent or rolled without cracking the coating. A piece of aluminum thus coated is said to have been immersed in a salt solution for two months without showing the slightest trace of corrosion.

The Painting of Agricultural Implements

Painting Methods Differ Considerably Depending Upon the Nature of the Product—The Method of Mixing Paint is Described, Also Other Items Which Will Prove Valuable For Future Reference

By J. H. MOORE

IT is hardly necessary to state that practically all agricultural implements manufactured are noted for their bright and cheering appearance when leaving the factory.

True, they lead a varied life, on reaching their destination, for some farmers take care of their machines, while others allow them to lay out in some field, rain or shine, winter or summer, with the result that in a short time the cheerful look disappears to be superseded by a dilapidated appearance which is far from comforting.

This condition is, of course, up to the farmer himself. and yet, we could not commence with this article without giving our personal comment on the fact that if farmers could only see the pains spent in preparing and painting the machines they abuse, they would be more careful in future.

The Procedure Adopted

Taking it for granted that the various pieces have reached the manufacturing stage where the painting operation comes in natural sequence, we will first consider how the paint is prepared.

The various colors, of which there are quite a few, come to the factory in powder form, or in other words, in dry color form. Depending on the color to be mixed, the painter, or paint mill operator, as he is termed, takes the dry color and places it in an upper can above the grinding mill. He also places the oil which is to be mixed with the dry color in a adjoining pan. Should readers not be familiar with the appearance of a paint mill, we will ask them to consider in their mind's eye, two grindstones revolving slowly in a horizontal position.

FIG. 2—DIPPING McCORMACK MOWER FRAMES.

FIG. 1 NOTE THE TROLLEY AND HOOK ARRANGEMENT.

Imagine these stones grooved with grooves about 1-8-in. wide, and semicircular in form, each groove leading to the centre of the stones. The size of the stones depends entirely on the capacity of the paint mill.

Directly above the stones is a hopper in which is an agitator somewhat after the shape of a ship's propeller. This should give a fairly good mind picture, so let us proceed to the actual mixing of the paint.

The dry colors, and oils, are now allowed to run into the hopper, where the agitator mixes the two quite thoroughly. The paint, which is now of a thick creamy nature, passes through the grooves of the stones, into a pan placed for the purpose. The paint is thinned out at later stages to suit requirements. Briefly, this explains the method of preparing the different colors. Usually there are 12 grooves to each stone, but again

(Continued on page 306.)

Calculations and Analysis of Riveted Joints

This Article Instructs You How to Design a Riveted Joint of Any Required Efficiency—The Calculations Are by no Means Complex and Are Easily Followed.

By T. H. FENNER, Editor Power House

THE efficiency of a riveted point is expressed always as a percentage of the strength of a solid plate. When holes are drilled or punched out of a plate to allow of riveting, the plate is weakened by the amount of metal cut out. If we have a plate of one square inch section, and remove .25 square inches in drilling, the section remaining is only .75, and the resistance of the plate to stress will be only 75 per cent. of its original resistance. This would represent what is known as per cent. of plate strength to solid plate. This is only one factor. The second factor is the proportion that the strength of the rivets bears to the strength of the solid plate. This will depend on the diameter and number of rivets in the unit section of plate considered, and is also expressed as a percentage. We shall consider the means of arriving at these efficiencies shortly.

There are several styles of riveted joints, and two distinct classes. The lap type of joint is so called because it is made by lapping the edges of the plate over each other and riveting them together. The second type is known as a butt joint and is made by bringing together the edges of the plates to be joined and placing a broad plate over them, riveting all three plates together. In many cases two cover plates are used. These two types of joints are subject to various modifications. Thus a lap joint may be single, double, or treble riveted and the rivets may be placed in regular rows or in staggered rows, known as chain or zig-zag riveting. The butt strap joint amy be made with one or two straps, with equal or unequal straps, with double, treble or quadruple riveting. The type of joint selected will depend upon the pressure to be carried, cost of manufacture and rules of the province in which the boiler is to work. The cut here shown illustrates the type of joints mentioned above.

To Find Efficiency of Joint

The efficiency of a riveted joint varies with the diameter of rivets, pitch of rivets, number of rivets in a pitch, and the thickness of the plate. In considering riveted joint efficiency, the unit of plate area considered is always contained within a pitch or between the centre lines of two adjacent rivets. Where there is more than one row of rivets the pitch of the rivets in the outer row is taken. We will explain each type as we come to them. The most simple is of course the single riveted lap joint. Suppose we have a plate of 5-16 inch in thickness, and with ⅝ rivets pitch 2 inches. We have to consider the strength of the joint as compared to the solid plate. We will consider the plate to be of 60,000 lbs. tensile strength. We shall therefore have a section, before any drilling is done, of 2 x 5-16=⅝ square inches. This section will have a resistance of 60,000 x ⅝=37,500 lbs. Now, after drilling, the amount of metal removed will be in diameter just equal to the diameter of one rivet because in the section we are considering there will be just half a hole on each side. A glance at the sketch which shows the pitch of line passing through the centre of rivets will make this clear. Therefore the amount of metal removed will be equal to the diameter of one rivet multiplied by the thickness of the plate, or $\frac{5}{8} \times \frac{5}{16} = \frac{25}{128}$. This amount substracted from the original area will give the section remaining, and if this remainder be divided by the original section we will have a fraction representing the proportion of original section remaining. To express this as a percentage we multiply by 100. Now to follow out the procedure step by step.

Let P= pitch
d=diameter of rivet.
t=thickness of plate.

We have a plate section of pitch P, and thickness t, the area being Pt. The rivet area will be equal to dt, so that when the holes are drilled we shall have

$$Pt - dt = P - d$$

the t on each side cancelling out.

The proportion of plate section remaining is $\frac{P-d}{P}$ and the percentage of plate to solid plate is $\frac{P-d}{P} \times 100$. Substituting figures, we get

$$Pt = 2 \times \frac{5}{16}$$

$$dt = \frac{5}{8} \times \frac{5}{16}$$

$$Pt - dt = 2 \times \frac{5}{16} - \frac{5}{8} \times \frac{5}{16}$$

$$P - d = 2 - \frac{5}{8}$$

$$\frac{P-d}{P} = \frac{2 - \frac{5}{8}}{2}$$

$$\frac{P-d}{P} \times 100 = \frac{2 - \frac{5}{8}}{2} \times 100$$

$$= \frac{2 - .625}{2} \times 100$$

$$= \frac{1.375}{2} \times 100$$

$$= 68.75$$

So that the proportion of plate strength to solid plate is 68.75 per cent.

This formula is always used, and may be set down

$$\frac{P-d}{P} \times 100 = \text{per cent. of plate strength to solid plate.}$$

In the Ontario regulations the plate efficiency is symbolized by the letters Kt, so the formula is

$$\frac{P-d}{P} \times 100\,Kt$$

The next point to consider is the efficiency of the rivets in the joint. This is the proportion that the area of the rivet in the pitch limit bears to the unit section of plate. As rivets are not as strong in resisting shearing stresses as they are in resisting tensile stresses, an allowance must be made for this difference. The Ontario regulations use the constant C, and this is expressed

$$C = \frac{\text{Shearing strength of rivets}}{\text{Tensile strength of plate}}$$

C may be taken as
.85 for iron rivets in iron plates
.70 for steel rivets in steel plates.
.65 for iron rivets in steel plates.

In the joint we are considering there is but one rivet in the pitch, and as there are but two plates which the rivets pass through they are in single shear. We will then have an area of d×d×.7854, divided by the area of the unit section, which is P×t. This is expressed in the formula:

$$\frac{a \times n}{P \times t} \times C \times 100 = \text{per cent. of rivets' strength to solid plate.}$$

So we have

$$\frac{5 \times 5 \times .7854 \times 1 \times 16 \times C}{8 \times 8 \times 2 \times 5} \times 100 = Ks$$

This worked out becomes, if we take C as .85

$$\frac{5 \times .7854 \times 85}{8} = 41.72 \text{ per cent.}$$

If we neglected the constant C we would get about 40 per cent. This lowest percentage is the one used in calculating the working pressure of the boiler.

In the previous joint considered the plate strength was 68.75 while the rivet strength was only 41.72.

A single riveted lap joint should be about 50 per cent. strength, so that

there is evidently some factor that requires altering. As the plate strength is higher than the rivet strength, it is observed that the factor that is wrong is the pitch. This is arrived at by considering that the plate is of minimum thickness, and the rivet cannot be decreased in diameter. As the pitch is a divisor in the formula for finding rivet strength, it is plain that by decreasing this factor the rivet strength percentage will be brought up. How much must we alter it to get the required figure? We can find that out very easily.

The formula for rivet strength we have seen is:

$$\frac{a\times n}{p\times t}\times C\times 100 = \%\text{ of rivet strength}$$

Now, let us insert the quantities we know. We have 50 per cent. for rivet strength, the other factors, excepting p remaining the same, and it is p we want to find. So we have

$$\frac{5\times 5\times .7854\times 1\times .85\times 100\times 16}{8\times 8\times p\times 5} = 50$$

Then, P is the unknown quantity. We will work this out. First by cancellation we simplify the expression and get

$$\frac{5\times 5\times .7854\times .85}{p} = 50$$

Transferring we get

$$50p = 5\times 5\times .7854\times .85\times 5$$

$$p = \frac{5\times 5\times .7854\times .85\times 5}{50}$$

$$p = 1.66$$

The nearest fraction to this is 1⅝. Let us see how this works out on the plate strength. We have

$$\frac{p-d}{p}\times 100 = \%\text{ of plate strength}$$

Substituting figures we get

$$\frac{1\frac{5}{8}-\frac{5}{8}}{1\frac{5}{8}}\times 100 = \%$$

This is simpler expressed in decimals, thus

$$\frac{1.625-.625}{1.625}\times 100 = 61.53\%$$

This is about right, and we have a better balanced joint, with 61.5% plate and 50% rivet strength.

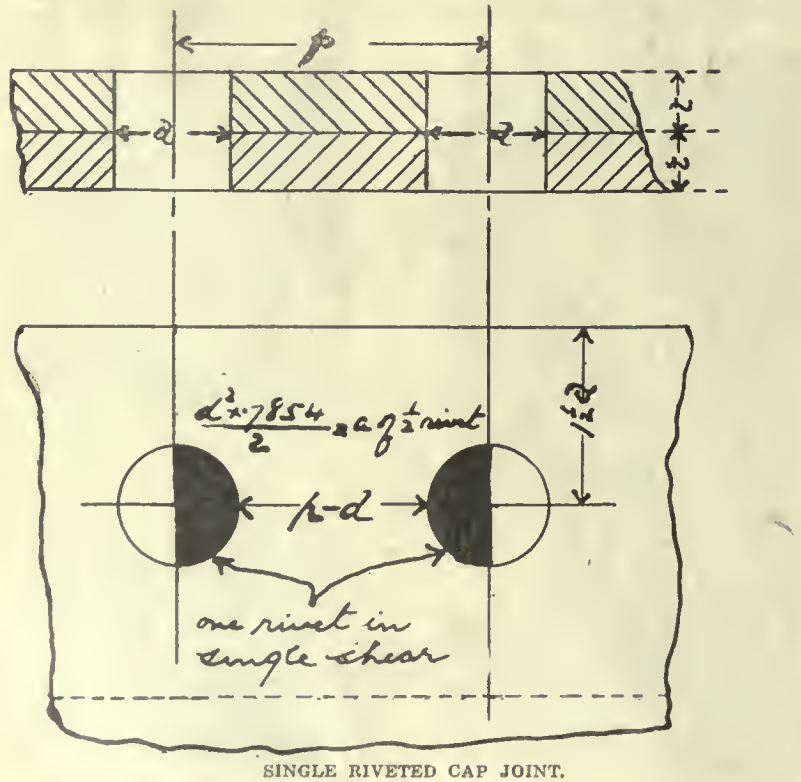
Analysis of Riveted Joints

In considering riveted joints, the various ways in which they may fail must be considered. The joint we are dealing with, being the most simple kind, has the least possible ways of failing. It can fail through the shearing of the rivets, and as there is only one rivet in the pitch limit the resistance of the joint to failing in that way will be the shearing strength of one rivet. It may fail by the plate tearing between the rivet holes, or it may fail by the plate crushing in front of the rivets.

First of all consider the strength of the solid plate. We have a pitch of 1.625 inches, with a thickness of 5-16 of an inch, and a tensile strength of 60,000 lbs. per square inch. The strength of the section will then be

$$p\times t\times 60{,}000$$
$$= 1.625\times .3125\times 60{,}000$$
$$= 30468.75 \text{ lbs.}$$

Then the strength of one rivet in single steel will be if tensile strength of rivet stub is 51,000 (.85 of plate strength) $\frac{5}{8}\times\frac{5}{8}\times .7854\times 51{,}000$.



SINGLE RIVETED CAP JOINT.

This worked out is 15,300 and the percentage to the solid plate is

$$\frac{15{,}300\times 100}{30{,}468.75} = 50.2\%$$

The resistance offered by the plate to tearing between the rivet holes will be

$$p-d\times t\times 60{,}000$$
$$\text{or } (1.625-.625)\times .3125\times 60{,}000$$
$$1\times .3125\times 60{,}000 = 18{,}750$$

and the percentage to the solid section will be:

$$\frac{18{,}750\times 100}{30468.75} = 61.53\%$$

This is in exact agreement with the previous result.

We must now consider the plate crushing in front of the rivet holes. We will have a section of plate equal to the diameter of one rivet and the thickness of the plate. The crushing strength of good boiler plate is about 90,000 lbs., so that we have

$$\frac{5}{8}\times 5\text{-}16\times 90{,}000 = 17571$$

This gives

$$\frac{17571\times 100}{30468.75} = 54.3\%$$

which is higher than the rivet stength percentage and may therefore be neglected.

We may say that a joint of this kind is practically never used in the longitudinal seams of a steam boiler, as its low percentage of strength would penalize every other part of the structure. However, they are sometimes met with on steam domes, where the small diameter in comparison to weight of plate elbows allows a low percentage joint to be used. In tank work, where the thickness of plate is much more than is necessary to resist the pressure, a single riveted lap joint is often used. For purely steam boiler work it is hardly to be considered. The next type of joint, and one very widely used, is the double riveted lap joint.

The Double Riveted Lap Joint

This joint has two rows of rivets, and two rivets in a pitch. It is usually designed for a strength of about 70 per cent. of the solid plate rivet strength and plate strength being approximately equal. The same formulae are used in making the calculations, but a new factor is a formula for determining the distance between the rows of rivets. The Ontario regulations prohibit chain riveting, all rows of rivets having to be staggered, or zig-zag.

Let us take a concrete example and work it out, which is the best way of explaining it. Let us assume we want a boiler built of ⅜ inch plate and having a double riveted lap joint of about 2 per cent. strength. We want to get the other dimensions. The diameter of rivet may be taken as ¾ inch, or double the thickness of the plate. Very often in practice the rivet hole will be 13-16 in this size of plate, and of course the rivet size after driving

will be the same as the diameter of the hole. Using the larger diameter in the calculations makes a slightly higher percentage of rivet strength and a slightly lower plate strength. However for our purpose we will consider the diameter as ¾. Now we want to find the pitch that will give the requisite strength with this diameter of rivet. We come back to the formula.

$$\frac{p-d}{p}\times 100 = \%\text{ of plate strength}$$

Substituting we get

$$\frac{p-d}{p}=.72$$

$$p-d=.72\ p$$

$$d=.28\ p$$

Then if d=.75 we get

$$.28\ p : p :: .75 : x$$

which gives

$$\frac{.75\ p}{.28\ p}=2.679 \text{ inches}$$

as the pitch we require. Knowing the diameter of rivet and thickness of plate, and number of rivets in a pitch, we could have found the pitch from the formula for rivet strength, as we did in the case of the single riveted joint. We will in this case, see how the pitch we have found works out for rivet strength. We have

$$\frac{a\times n}{p\times t}\times C\times 100 = \%\text{ rivet strength}$$

Substituting figures we have, using .70 as the constant C in this case, and 2 11-16 as the pitch

$$\frac{3\times 3\times .7854\times 2\times 70\times 16\times 8\times 100}{4\times 4\times 43\times 3\times 100}=\%$$

This worked out gives a percentage of 61.37, which is too low. We wish to make our joint about even, though if the plate strength is a little higher than the rivet strength it is all to the good, as the plate strength may deteriorate in time, through the corrosion or thinning of the plate, which will not likely occur with the rivet.

We can use still another method if we wish, and that is to equate the two strengths to each other, and thus arrive at a pitch that will satisfy both.

This means that if the strength is to be equal, the two formulas must be equal to each other. Let us state this in the form of an equation. We have

$$\frac{p-d}{p}\times 100 = \% \text{ and } \frac{a\times n\times C}{p\times t}\times 100 = \%$$

If these % are equal the other sides must be equal, so we have

$$\frac{p-d}{p}=\frac{a\times n\times C}{p\times t}$$

$$p-d=\frac{a\times n\times C\times p}{p\times t}$$

$$p=\frac{a\times n\times C}{t}+d$$

Here we have arrived at an expression for pitch which should satisfy us. Let us substitute figures and see

$$p=\frac{3\times 3\times .7584\times 2\times 8\times 70}{4\times 4\times 3\times 100}+\tfrac{3}{4}$$

$$p=2.39, \text{ say } 2.4$$

so we get 2.4 as a pitch. Let us try this again for our plate and rivet strength. First for plate percentage:

$$\frac{2.4-.75}{2.4}\times 100=68.75$$

Then for rivet strength

$$\frac{3\times 3\times .7854\times 2\times 5\times 8\times 70\times 100}{4\times 4\times 12\times 3\times 100}=68.72$$

Here we have got a perfectly evenly balanced joint, and though it is some 4% lower than we at first determined on, that is not a very serious matter.

Let us see now how this joint stands comparison in its resistance to failure at different points. It may fail by rupturing between two rivet holes in the outer row and shearing one rivet. It may fail by shearing two rivets, or by tearing between the rivets on the inner row. It can also fail by crushing in front of the rivets in the outer row, and shearing the inner rivet, or by shearing the rivets in the outer row and crushing in front of the rivets in the second row. Let us take these in order. First the unit section is $p\times t\times 60{,}000$

$$2.4\times .375\times 60000=54{,}000$$

If the plate tears between two rivets on the outer row, and shears the rivet in the inner row it will have to overcome a resistance of

$$60000\ (p-d)\ t+a\times .7\times 60000$$

That is, the plate has diameter of one rivet, plus the area of one rivet in single shear, whose resistance to shearing is .7 that of the plate tensile strength. Substituting figures we have

$$(2.4-.75)\times .375\times 60000+75\times .7854\times 42000$$

which gives 74.250 or more than the solid plate. If it fails by shearing two rivets we have

$$a\times 2\times 42000$$

$$=.75\times .75\times .7854\times 2\times 42000$$

$$=37102 \text{ lbs.})$$

$$\text{which is } \frac{37102\times 100}{54000}=68.7\%$$

of the solid

If it tears between two rivets on the inner row, we shall have again

$$\frac{(p-d)\times t\times 60000}{54000}=\frac{(2.4-.75)\times .375\times 60000}{54000}=68.7\%$$

If it crushes the plate in front of the rivets in the outer row and shears one rivet in the inner row we have then

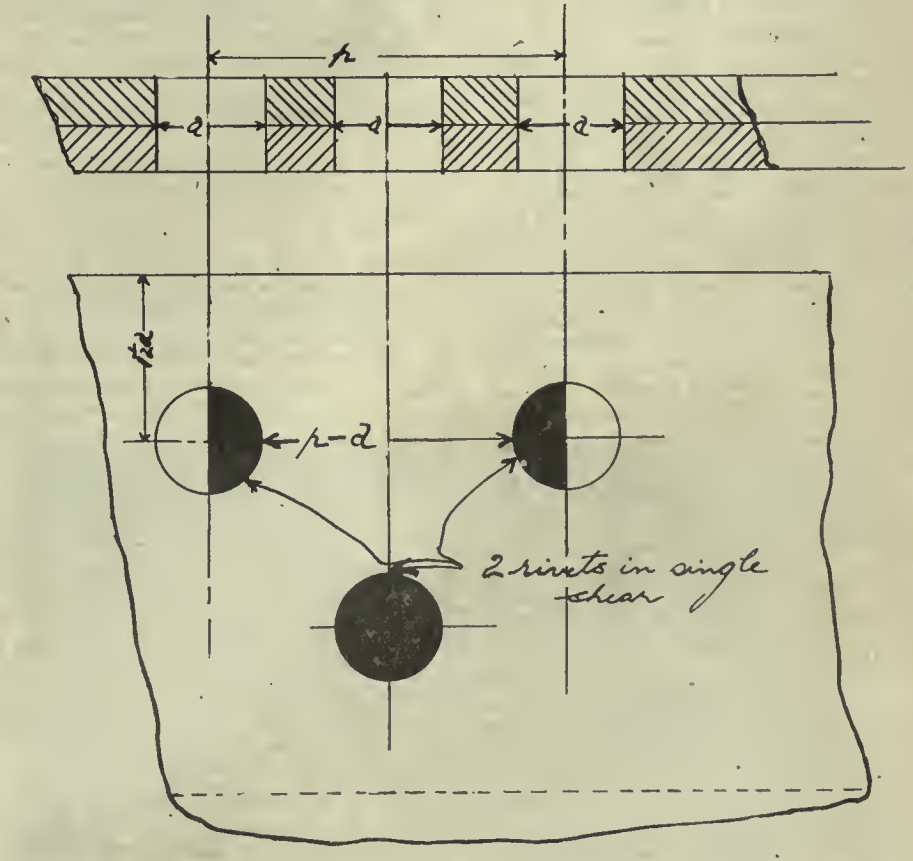
$$(d\times t\times 90000)+(a\times 42000)$$

$$(.75\times .375\times 90000)+(.75^2\times .7584$$

$$42000)=43872.3$$

$$\text{and } \frac{438723}{54000}\times 100=81.2\%$$

which is much higher than either the plate or rivet %. The last two cases are exactly the same as each other so we see that 68.7% is the strength of the joint. The minimum distance between



DOUBLE RIVETED CAP JOINT.

rows of rivets is found from the formula.

$$\frac{(11\frac{1}{2}+4\ d\ (p+4\ d)=\text{minimum distance}}{10}$$

The treble riveted lap joint shown in the sketch is not very much used, as there is not much advantage in employing it. The percentage obtainable is not much greater than with the double riveted joint, and the cost of manufacture is increased. The calculations are made exactly in the same way as for a double riveted joint, excepting that there are three rivets in single shear instead of two. It may fail by the plate breaking between the outer rivets and shearing two rivets. It may crush the plate in front of one rivet and shear two rivets. It may shear three rivets. The plate may break between the rivets in the centre row and shear one rivet in the inner row. It may fail between the rivets in the inner row, and this of course is the weakest part, so that $\frac{p-d}{p}$ is the governing factor.

The calculations would be as follows:

1st case — $(p-d)\ t\times 60000+a\times 2\times 42000$.

2nd case—$d\times t\times 90000+a\times 2\times 42000$.

3rd case—$a\times 3\times 42000$.

4th case — $(p\times d)t\times 60000+a\times 42000$. 42000.

5th case—$(p-d)\ t\times 60000$.

In the next article we will take up butt joints.

STEEL TREATERS

J. H. Moore

The writer had the pleasure of attending the recent convention of Steel Treaters in Philadelphia and brings back pleasant memories of the event. The advance notices predicted were lived up to in every respect, and the various exhibits were both neatly and efficiently displayed. The floor space was arranged in ideal style, and those attending had a splendid opportunity to view each exhibit without confusion. To speak of any particular exhibit is unnecessary, as we printed in a previous issue the firms who were to be represented. Enough to say that every concern showed good taste in their display and ideas of considerable educational value were to be found at the various booths.

The meetings in the lecture room were of vital importance, over seventy papers being presented. Some of these were presented by the authors themselves, others by title. We intend issuing through our columns some of these papers, so that readers will get the next best thing to an actual visit. A glance over our list previously printed will show the subjects covered in these papers and will emphasize the treat in store.

The amalgamation of the Steel Treaters Research Society and the American Steel Treaters Society took place on the T[illegible]day morning, Sept. 14th, and the new body is now known as the American Society for Steel Treating. The joining of these two bodies makes the society even a more important one than before. To go into all the details is impossible at this time, but as soon as the official proceedings are issued, we will give more particulars.

PAINTING IMPLEMENTS

(Continued from page 302.)

that depends on the stone, and the paint being milled.

The various methods of painting are many, varying from the hand to the dip method. In some cases the nature of the pieces necessitate the painting by hand, in order to protect some other portion, for in many cases the parts are painted after partial, or even complete assembly.

Special trucks are used where painting by hand is necessary, these trucks being so constructed that the workman can get at all parts of the piece without any trouble. The number of coats given the piece depends entirely on its duty, and exposure to weather when in use. As a general rule the pieces are varnished in addition to being painted.

Wherever possible the work is handled by air hoists, this speeding up the operation considerably. All work is carefully routed, for a delay in any one portion would more than likely hold back subsequent operations.

A good method of handling their product is shown at Fig. 1. In this case the hooks are of individual nature running on a single trolley line as shown. The work being performed is that of varnishing mower frames, and the manner of suspension is self-apparent. By this means the workmen can easily reach all parts to be varnished without undue effort.

The method shown at Fig. 2 is known as the dipping process, and the work being dipped is one of the McCormack Mower Frames. This portion gets two coats of paint and one of varnish, and as can be noted an air hoist is used for handling purposes. The paint in these dip tanks is kept in constant motion, some by screw agitators and others by the use of air, thus ensuring a thoroughly mixed paint.

Ideal ventilation is provided throughout the entire paint building, and every convenience for the workmen has been provided.

Galvanizing, What it is and How it is Done

Describing and Illustrating the Process as It is Practised in One of Canada's Leading Industries, together with a Short Story of Its Origin.

By F. H. BELL, Editor Canadian Foundryman

THE subject of galvanizing is one which will be read with interest by many foundrymen, and being a comparatively simple process, and in many respects a part of the foundry business, I will endeavor to describe in a brief way how it is accomplished.

There are two processes by which galvanizing is performed. The original method, and the one from which the art derived its name, is that of an electro-galvanic battery operating on a bath in which zinc anodes are placed along with the articles to be galvanized, and is in many respects similar to electro-plating of any kind. The battery which has since been succeeded by the electric dynamo was originally the work of Aloysius Galvani, an Italian electrician, who was born at Bologna, Italy, in 1737, and died in his native town in 1798. Galvani did not discover the art of galvanizing, but one, Febroni, observing that the zinc in batteries became oxidized in contact with the acidulated water, and adhered to copper or whatever metal it came in contact with, adopted the name of galvanize. Electro-galvanizing is still practised on some classes of work, but it is not on this process that we will dwell on this occasion.

While the word "galvanize" rightfully belongs to the genus "electrique," it has become so associated with the process of zinc plating that its original meaning has been forgotten. As a matter of fact it never rightfully belonged to the original process for the reason that Galvani's discoveries and inventions never reached the stage where the zinc pole was used, but his successes gave his contemporary, Alessandro Volta, a foundation upon which to build, and which led up to the discovery of the zinc and copper positive and negative poles, known as the "Voltaic Pile," but usually referred to as the "Galvanic Battery."

The process of galvanizing which I will attempt to describe on this occasion is that of immersing the article to be treated in a vessel of molten zinc. While this may appear to be simply a mechanical process it is in reality a chemical process, although perhaps unbeknown to the mechanic who performs the operation. In chemistry there are two elements to be considered, one the metallic and the other the acid. Different acids act differently in contact with different metals, but we will not go into the chemical aspect of the subject, suffice it to say that the acid and the heat generated by the electric current caused the two metals to adhere to each other in the former process, while the acid and the heat generated by fire cause the two to adhere to each other in the process about to be described.

In the illustration will be seen a typical galvanizing plant, being that of the Goold, Shapley and Muir Co., Limited, Brantford, Ont. This company manufactures a line of windmills, pumps and sundry other specialties which require galvanizing, and incidentally do an enormous amount of the custom galvanizing which is done throughout Canada. At the extreme right of the illustration and behind the workman is a large wooden vat, a portion of which is shown. This vat is approximately 20 feet long, six feet wide and two feet deep, and contains diluted sulphuric acid. It is connected up to steam pipes for the purpose of heating the acid, not by radiation, but by the direct action of the steam being forced into the acid. The vat, as we have seen, is of wood. The acid would dissolve an iron one, but strange as it may seem, does not affect the wood.

Next to this and in front of the workman is another vat containing muriatic acid.

To the front of the picture and behind the pile of pipes will be seen the end of another vat containing water.

Beyond this will be seen one of the kettles in which the molten zinc is contained, and at the rear left corner of the room will be seen another of the kettles.

At the rear, to the right, will be seen the open doors of the hot air ovens. Thus we have the equipment of a modern galvanizing plant.

The kettles are of electrically welded steel, one and three-quarter inches in thickness on the sides, slightly thicker on the bottom, and flanged at the top. These kettles are built into furnaces with fire doors the entire length. Soft coke is the fuel used and the metal is kept melted continuously. One of these kettles is long and shallow, being in dimensions 21 feet long, 22 inches wide and 30 inches deep, and with a capacity of approximately 20 tons of melted metal. The other kettle is 5½ feet by 8 feet by 22 inches, and holds approximately 16 tons of metal.

By having two kettles of such different dimensions it is quite possible to galvanize almost any piece which could be offered.

When material is brought to be galvanized, if it is a casting with sand burned into it, the sand should be removed by means of an emery block or file, and if necessary, by the application of hydrofluoric acid, which will dissolve the silica even though burned into glass. A plant where much of this would require to be done would have a vat of hydrofluoric acid, but where the bulk of the work to be done is on sheet metal this is not necessary.

For the regular run of work such as is done at this establishment, the articles to be galvanized are put into the sulphuric acid, where they may remain all night if the acid is not boiled. In the day-time steam is turned into it, keeping the acid in a boiling state. This hastens the action and several lots may be done in one day. When the article shows that all scale has been loosened, it is removed from the acid in a slimy state (from the action of the acid) and is taken to the water vat and washed. From this it is taken to the muriatic acid vat and allowed to remain in this for a short time, when every vestige of the first acid will be removed and the article will be perfectly clean metal with a thin film of chloride of iron on the surface. Muriatic acid is a combination

Some Interesting Examples of Gauge Making

Making Gauges is at Any Time a Ticklish Proposition, as Accuracy is the Main Consideration—Herein is Described, from Practical Engineer, How Various Gauges Were Completed.

By A. G. ROBSON, A.M.I.Mech.E.

AN internal cylindrical gauge is referred to in Fig. 1 as a plug gauge. After the steel is cut from a bar it should be annealed and then turned in the lathe, the diameter being made 0.010 in. larger than the finished size of the plug. The surface should be fairly smooth without any irregularities. The plug is made "dead" hard by uniformly heating to a very bright red and suddenly cooling in water; it will then be found to have increased in diameter by 0.002 in. to 0.003 in. A grinding arrangement is now secured in the slide rest of a high-speed lathe, while the plug is placed between the centres. In Fig. 1 the plug is indicated by the letter P, and the emery wheel by EW. H is the holder, FP the fixed pulley, and B the bearings. An additional countershaft is required for driving the emery wheel. The arrows indicate that the directions of rotation of plug and emery wheel are opposite. The bearings must be very carefully fitted and should be examined from time to time. The grinding is done by moving the hand slide rest whilst the plug and wheel rotate, and should be continued until the plug is .001 in. larger than the finished size.

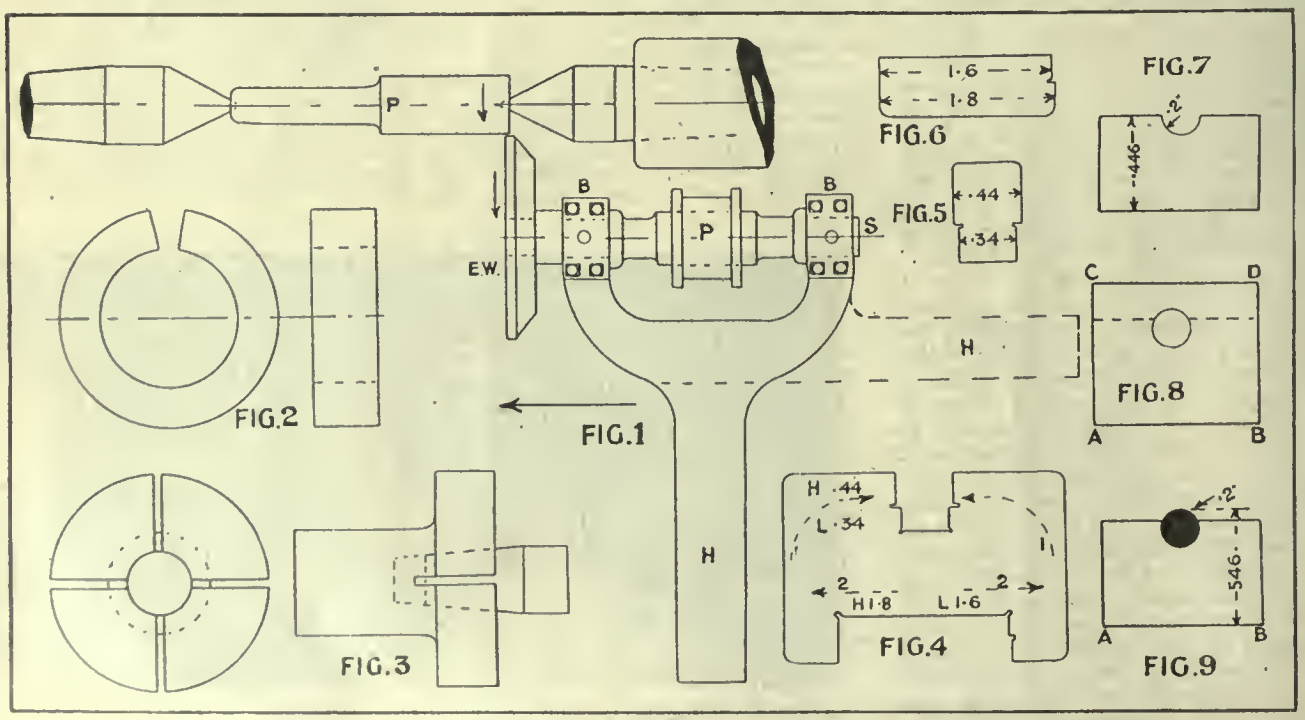
Lapping

The excess of .001 in. on the plug is removed by lapping off, a process which will remove any unevenness which can only be detected by applying the micrometer, and at the same time will produce a smooth, shiny surface. The lap consists of a lead ring (Fig. 2), which is bored to fit just over the plug, but with a portion removed as shown. The lathe being started, the plug rotates whilst the lead ring is held stationary by hand, and oil and fine emery powder are placed in the slot in the ring. The ring will exert a pressure upon the plug and the emery powder and oil will be sucked in around it. The powder tends to become fixed in the lead surface, and consequently the lapping is more effectual. The plug should be tested by the micrometer to see that it is parallel.

A plug of lead is used for lapping the hole, and about .001 in. would be allowed for this operation after grinding. (It is advisable in this case to allow slightly more than 0.010 in. for grinding. In the case of the internal gauge above described any increase on the diameter due to hardening is an advantage, but any increase on the diameter of an external gauge will result in there being less to grind out of the hole.) The lead plug would be turned to fit the hole and the smaller diameter in Fig. 3 would be secured in the lathe chuck. The lathe is started, and whilst the lead plug revolves the ring gauge is held over the plug to prevent rotation. The ring is gently moved to and fro to secure even lapping. Oil and fine emery powder are placed on the plug, and as the lapping proceeds the powder tends to "pin in" the lead surface. If a large number of holes require lapping provision must be made to compensate for the wear on the lead plug. It is therefore sawn in four places and a conical hole made in the end. As the plug wears a slight tapping of a steel pin shown in Fig. 3 will spring the lead and increase the diameter.

Plate Gauges

There are many varieties of plate gauges. A very common one is shown in Fig. 4. If a number of these were required, cast steel blanks would first be cut from ⅛ in. plate. After being roughly milled the faces and sides would be cleaned up and the particulars of the gauge stamped upon the face. The letters H and L refer to the high and low sizes respectively. The next operation consists of making "working checks" (working check gauges), which will appear as shown in Figs. 5 and 6. The making of working checks is of great importance. The pieces of plate are filed and scraped until about 0.001 in. larger than their sizes, after which they are case-hardened by ferro-cyanide of potassium being placed on the faces and edges when heated, and they are then plunged into water. By washing the gauge in water the powder will easily be removed. The checks should now be lapped. A piece of copper about ⅛ in. or 3-16 in. diameter has two flat surfaces filed on one end. Fine emery powder and oil are then mixed together and the copper lap is placed in the mixture and rubbed on



THIS VIEW INCLUDES FIGS. 1 TO 9.

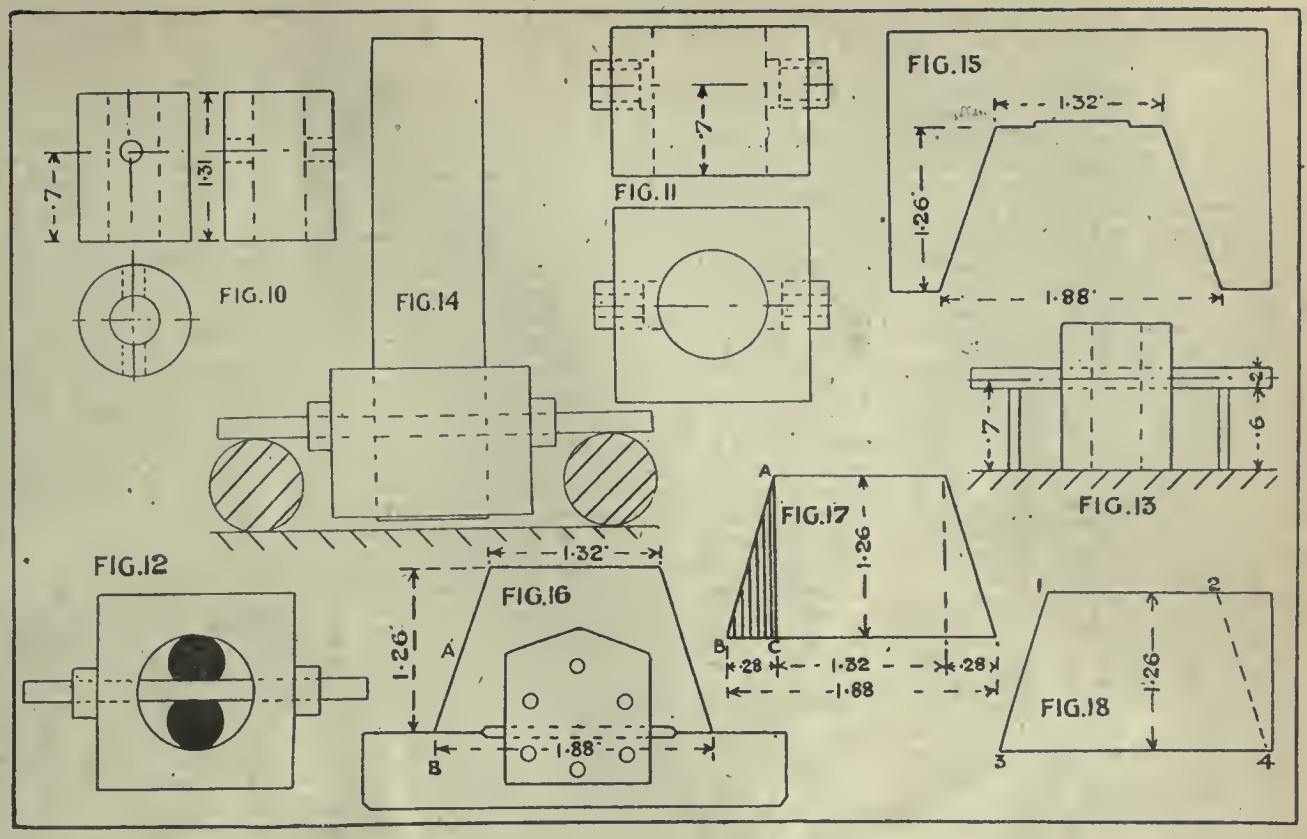


FIG. 10 TO FIG. 18 INCLUSIVE.

the finished faces of the checks. This gives a bright surface and a remarkably good finish. The checks should be occasionally tested by the micrometer during the process of lapping, and a small straight-edge applied to the faces.

Working Limits

Working limits are usually allowed on gauges, so the checks must also be made within these limits. The high measurement is given as 1.8 in. If 0.0003 in. were allowed on this high size then the size of the check should be the mean of this added to 1.8 in.; that is, 1.80015 in., or one and a half ten-thousandths larger than 1.8. The check would also be correct if it were made 1.8003 in., but then it would have to fit tightly in the gauge, as this measurement is the high limit to the high size of the gauge.

In the case of the low measurement, 1.6 in., assuming the same allowances were permitted, this part of the check should be the mean of 0.003 in. deducted from 1.6 in.; that is, 1.59985 in., which is one and a half ten-thousandths less than 1.6 in.

Fitting of Checks

The gauges should now have the checks fitted to them. The first step is to obtain a true surface on one side of the openings shown in Fig. 4 and then work the other faces to suit the checks. It is well to make the checks tight-fitting at this stage prior to case-hardening. Gauges will behave in a very peculiar manner during the process of case-hardening, but it is found that by heating them to the least temperature sufficient to fuse the case-hardening powder there is very little change in size after the gauge is immersed in water. Overheating will prevent the gauge from contracting to its original size and it remains larger than the check gauge. The amount may be as much as 0.002 in. When this is the case and the gauge has to be closed in to fit the check it is hammered in the direction of arrows, 1, Fig. 4. Care must be taken that the high measurements of the gauge are not increased also. Should the gap in a gauge be too small and require enlarging the metal face should be hammered lightly in the direction of arrows 2, Fig. 4, commencing from the centre. Having now made the gauges nearly to fit the checks, the surfaces of the gauges must be lapped by the copper lap until the checks fit easily by hand. Care should be taken to prevent the checks becoming affected by the heat from the hand or by holding them too near the light. Gauges may be made a "proper" fit to a check gauge in the warm atmosphere of the workshop at night, but in the low temperature of the following morning they will be found to have altered. In working to the ten-thousandth part of an inch due regard must be paid to the temperature of the room, and to assist in this direction micrometers should be mounted on wood or metal stands.

External Semi-Circular Gauge

In Fig. 7 an external semi-circular plate gauge is shown. The important parts of this gauge are the size of the hole and the semi-circle. In Fig. 8 a piece of ¼ in. plate A B C D is shown. The face A B C D should first be trued up by a grinding machine. This face should now be placed upon the face of a magnetic chuck, secured to the table of the grinding machine, whilst the opposite face is ground. The position of the hole in the plate is not very important. In Fig. 8 the hole is drilled as shown. As the finished size of the semi-circle is 0.2 in., then the hole in Fig. 8 should be about 0.003 in. smaller than the diameter, 0.4 in. The hole is enlarged so as to be 0.001 in. less than 0.4 in. This 0.001 in. is removed by lapping the hole. The size of the hole is finally determined by a lapped plug tightly fitting in. The plate is then sawn through along the dotted line.

It will be observed that this line is above the centre of the hole. Now the surface A B of the plate is made true by applying a straight-edge to it and removing the high places by an oil stone. When completed this lower surface, the plug is then inserted as shown in Fig. 9. The micrometer is then applied to ascertain the measurement from this surface to the top of the plug. In Fig. 9 this is shown to be 0.546 in. In order to have a semi-circle in the plate the distance from the centre of the plug to the base will be 0.546 in.—0.1 in. (the radius of the plug) = 0.446 in. The upper face is then filed and finally lapped until the measurement, 0.446 in., is obtained as shown in Fig. 7.

Cross-Hole Gauge

A cross-hole gauge is seen in Fig. 10. It consists of a piece of circular cast steel with a central hole. Two other holes (one on each side) are at right angles to the central hole and also in the same plane. The central hole would

first be drilled and lapped to the correct size; the gauges would then be turned on the outside by fitting a mandrel in the hole. A drill block is then made as shown in Fig. 11. It is a rectangular piece of steel, bored out to suit the outside diameter of the gauges. Two holes are drilled and these are then bushed. In order to test whether these holes are at right angles a rod resting on two smoothly turned pins of the same diameter is passed through the bushes (see Fig. 14). Another rod, with a hole through it to permit the first rod passing through, is placed in the block as shown. A square tried each side of the rod will show whether the holes are at right angles. To test the alignment of the holes a round pin has a tapered face filed on it, and by trying this pin as shown in Fig. 12 and measuring the distance it projects through the other side for each position the holes are checked for being in line with each other.

After the cross holes are drilled they should be finished by a rimer, which can also be used for rectifying the holes should they not be in the same plane or at right angles to each other. To finally determine the distance 0.7 in. two "slips" should be made. If the cross hole is 0.2 in. then the distance 0.7 in. is determined as shown in Fig. 13. A tight-fitting 0.2 in. pin is placed through the holes, and the two slips, which should be made 0.6 in., must just touch the pin easily.

A type of gauge introducing a little calculation is seen in Fig. 15. It is a simple plane surface gauge and the small undercut on the inner face is only clearance. It is at once apparent that the check will be to the shape and sizes shown in Fig. 16. It consists of two pieces A and B held together on a back plate by small screws. The piece B requires its upper face to be lapped true. Difficulty with the check will be experienced in making the piece A, as the micrometer cannot be used to determine the measurement 1.32 in. The easiest and most reliable means will be to find what the angle A B C in Fig. 17 measures. If this angle is accurately determined the measurement 1.88 could be measured by the micrometer, and then the 1.32 in. should agree when the height is 1.26 in. Looking at the shaded right-angled triangle A B C the base B C is found to be 0.28 in.

$$\text{Now the tangent of angle A B C} = \frac{\text{A C}}{\text{B C}}$$

$$= \frac{1.26}{0.28} = 4.5.$$

Looking at a table of tangents of angles, it will be seen that 4.5 is between the tangent of 77 deg. and 78 deg. The tangents are as follows:

Tan 78 deg. = 4.7046
Tan 77 deg. = 4.3315
∴ Difference for 1 deg. = 0.3731

Now the angle between 77 deg. and 78 deg. must be found. Let this angle be called 77.x deg.

Then Tan 77.x deg. = 4.5
and Tan 77 deg. = 4.3315

∴ Difference for 0.x deg. = .1685
but 0.3731 is difference for 1 deg.

$$\therefore 0.1685 \text{ is difference for } \frac{0.1685}{0.3731} = 0.45$$

∴ 77.x deg. = 77.45 deg.,

which is the angle A B C. The standard protractor in the workshop should be carefully set to this number of degrees. A piece of metal is next obtained and the two opposite faces rubbed down and lapped until they are 1.26 in. apart. The angle on one end, as shown in Fig. 18, should now be obtained by filing, rubbing down, and lapping. When the angle 1 3 4 agrees with the protractor the distance 3 4 should be made a few thousandths of an inch greater than 1.88 in.; then the angle 2 4 3 is obtained by the protractor. The whole face 2 4 should now be rubbed down and lapped until the distance 3 4 is 1.88 in. Care must be taken in checking the angle whilst this is being done, as unevenly distributed pressure upon the plate will cause it to alter. It will facilitate adjustment, and ensure the two faces of the check coming together if each face is undercut as shown in Fig. 16. The back plate is now drilled, and after the holes are marked off upon the two parts of the check these may be drilled. The check must be light-tight to the gauges, and whether this is so can be observed by holding the check and gauge upon a piece of glass up to the light.

GALVANIZING

(Continued from page 307.)

of chlorine and hydrogen, sometimes referred to as hydrochloric acid. This acid not only cleans the surface of the iron but eats into it, and the chlorine combines with the iron, forming the coating referred to. The article is taken in this condition and placed in the oven and dried with this coating on it. When thoroughly dry and preferably when still warm, it is immersed in the melted zinc. When dipping anything long like a pipe or even a flat plate it should be put into the zinc very carefully, one end first, and should be taken from the tank with equal care.

When the melted zinc comes in contact with the chloride of iron it becomes impregnated and the zinc is actually alloyed with the iron through the influence of the chlorine rather than adhering to the surface. The acid, while assisting in the work of securing the zinc to the iron, also attacks the melted zinc as well as the article being galvanized and also to a certain extent the tank in which the metal is melted. Oxidation also takes place and the effect of these various influences is to form a sort of dross or crystallized zinc, and, unlike zinc oxide or iron oxide which would float on the surface, this dross settles to the bottom, and if allowed to remain there would soon cause the ruination of the kettle. To avoid this lead is introduced, and the lead being heavier than the zinc or dross settles down to the bottom and as the dross settles it remains between the zinc and the lead, and is scooped out with a perforated ladle and pounded into iron molds, from which it is taken and shipped back to the refinery where it is again converted into good zinc.

As we have said a certain amount of oxidation takes place and that some of the oxide was in the dross which settled to the bottom, but as a matter of fact the percentage of oxygen in that material would be small. The bulk of the oxidized zinc gathers on the top and is skimmed off. Some of this will be seen in the pile in front of the tank. This would be much more in evidence were it not for the use of flux in the metal. The flux removes the oxygen from the metal and at the same time forms a covering on the melted metal which to some extent prevents it from further oxidation. The zinc is only exposed by skimming when a piece is to be dipped, and only at such a portion as is necessary to allow the dipping to take place. The flux used consists of sal-ammoniac and sawdust, and in some cases glycerine and sawdust. The pile of skimmings seen in the illustration contains a certain amount of good zinc which can be recovered.

As might be imagined, coats are not required in this department. The fellow with the coat on is only a visitor. The gentleman next to him is Mr. Wm. Lusby, who for the last 20 years has been superintendent of this department and knows the galvanizing business from A to Z.

This galvanizing room is but one department of the Goold, Shapley and Muir Co.'s works, and the windmills, etc., which require to be galvanized form only part of the output of this plant. Gas, gasoline and oil engines, stationary and portable, are among their products. They also manufacture a line of pumps, from the smallest kitchen pump to the largest of mining pumps. But the windmill which they have manufactured in unlimited numbers and which was their earliest venture, has gained such a hold on the public mind that the plant is commonly known as "The Windmill."

The company, in their various departments, employ some 300 hands, and were among the first to undertake the art of galvanizing in Canada.

In conclusion I would say that while galvanizing is a comparatively simple art, it represents quite an outlay. The electrically welded steel kettles constitute a big item, and the 30 odd tons of zinc at 18c. per pound, which is the prevailing price, is no small item. This being kept in a molten state year in and year out would consume a considerable quantity of fuel. But such is business.

RAIL BENDING PRESS

The Hydraulic Press Mfg. Co., Mount Gilead, Ohio, have placed on the market a hydraulic rail-bending press which has a capacity of 35 tons. It is of the horizontal type, and mounted on wheels so that it can be readily be moved into the position where it is to be used.

Temperatures for Heat Treating Carbon Steels

It is Well Known the Lowest Temperature Which Will Give the Best Results is the Best Temperature, But What is the Lowest Temperature?—This Question Has Puzzled Many.

By F. L. MOISTER

THE lowest temperature which will give the desired results is the best temperature. This leaves open the question—which is the lowest temperature.

Heat treatment begins with the ingot. The size of the ingot grain is in direct ratio to the rapidity in freezing. Rapid freezing means small grain, slow freezing means larger grain. In practice the ingot is stripped as soon as the walls have solidified enough to permit handling without danger of bleeding and immediately charged into the soaking pit. If the pit temperature is right the heat equalizes and freezing is normal. If too hot, as sometimes occurs, freezing is delayed. The writer is of the opinion that the wide variation in physical properties of steel of same melt and same product is due more to variations in size of ingot grain than to any other cause.

High temperatures and delayed cooling in rolling or forging mean large grain. Low temperature and normal cooling mean fine grain.

Some authorities claim that the lowest temperatures for annealing and hardening are always above recalescence. This is true for annealing, but even in that operation the lowest temperature above recalescence is best, for low annealing temperature with longer time is infinitely better than higher temperature. The low temperature annealed steel will be finer grained and superior in ductility and elasticity.

Consider forgings, both open and die; few forge shops pay much attention to the forging temperature; what they aim at is a soaking heat, the steel highly plastic, so hammer work is reduced to a minimum. The finishing work is often at such high temperatures that the grain grows in cooling and frequently the hot forgings are piled and cooling delayed. Delayed or interrupted cooling from high finishing temperatures induces grain growth.

A glaring instance of this occurred in a shop using their own make of smith's hand tools. A 4 in. flatter broke off at the base before it had been in use one hour. The fractured surface was very coarse grained and showed pronounced evidence of what might be termed "Acute Detail Fracture." The smiths, to a man, called it burned steel. The writer held it to be a case of slow cooling from a high finishing temperature.

The flatter was forged from a 2 in. x 2 in. bar of flatter steel, carbon .82, the bar was cut into lengths, handle hole punched, tapered to enter die, reheated a bright orange and flashed in the die with three blows of a trip hammer. They were piled while very hot and cooling delayed. Such tools were issued to the shop without further treatment.

The shank of the broken tool was quartered longitudinally and two diagonal pieces broken transversely by pressure. The fractures were very coarse crystalline, of pronounced fiery lustre, and there were no signs of bending before occurred.

The other two pieces were heated to 1,450 deg. F, held for some time to allow for lag, and cooled in the air. They were broken in the same manner. The fractures were fine grained, no fiery lustre, and the pieces had bent considerably before rupture occurred. This test proved the writer's contention, that the steel had been injured, not by burning, but by delaying cooling from a high finishing temperature.

Two flatters were taken from the same lot, heated 1,450 deg. F, cooled in the air. Then heated to 1,400 deg. F, and quenched in water. One was drawn to 900 deg. F, and the other to 850 deg. F, and both put on same work as the broken one. The first was in constant use for 26 days, had mushroomed to 3½ in. across the hammer end with but one slight crack showing. The second was in use for nine weeks, had curled down at hammer end, no chips had broken from it and it was good for many more weeks' service. An excellent tool.

In forging a cold chisel of carbon steel, the smith will heat the steel cherry red, forge it into shape with light blows and quench in water when the color is a dull red. It will be hard as a diamond but brittle, and drawing back to a straw color will make it tough and hard. A good tool. Had he quenched in water at cherry red the steel would be full of shrinkage cracks and the tool useless. He selected the lowest temperatures for his purposes.

The effect of quenching in water from too high temperatures can be seen by etching the face of most any make of machinists' hammers. The etched surface will show a network of fine shrinkage cracks which cause the steel to spall off in use. Some years ago the writer investigated such hammers which were causing injury to workmen by chips flying from them. Several makes were selected for the test and all but one make, when etched, showed the network of shrinkage cracks. Under an intensified work test—striking the face of an anvil with a full arm blow—some hammers spalled at less than 20 blows, and none showing cracks stood 50 blows. The ones that did not show cracks stood over 100 blows without spalling.

In heat treating locomotive forgings to a specification which called for:

Carbon	.40	.55
Manganese	.40	.70
Silicon	.10	.30
Phosphorus		.05 Max.
Sulphur		.05 "
Chronium		.30 "
Nickel		.40 "

55000 lb. Elastic Limit in forgings up to 4 in. dia. or 2 in. wall,

90000 lb. Tensile Strength in forgings up to 4 in. dia. or 2 in. wall,

50000 lb. Elastic Limit in forgings over 4 in. dia. or 3½ in. wall,

85000 lb. Tensile Strength in forgings over 4 in. dia. or 3½ in. wall.

20.5 per cent. min., elongation in 2 in. F. hold for heat to be equalized, and allow for lag, cool in air, with forgings separated so as not to delay cooling. out the steel in excellent condition for heat treating. The forgings were made by several smiths, observation showed widely varying finishing temperatures, and therefore the annealing temperature had to be held long enough to correct the grain in the hottest finished ones.

Heat slowly to 1450 deg. F., hold at that point till thoroughly heated, and quench in freely circulating water. Draw 950 deg. F. to 1000 deg. F. if 55000 lbs. Elastic Limit is required,

1000 deg. F. to 1050 deg. F. if 50000 lbs. Elastic Limit is required.

Temperature varying for carbon content and section of forging.

Tests made from such forgings gave perfect results. All forgings were accepted. The elongation and reductions were in excess of requirements and the fractures were fine, dense gray lipped.

Forgings quenched in oil from higher temperatures, when tested, did not have as fine grain, high elasticity or ductility. The fractures were not as regular and did not have the clear silky appearance of the water quenched.

A fairly wide range of quenching temperatures is possible, if tensile qualities only are desired, and the steel can be made reasonably uniform by varying the draw. But if tensile and shock resisting qualities are desired, the quench should be as low as possible so the grain will be fine and the draw low. The steel will have equal ductility, greater elasticity and thus superior shock resisting qualities.

Grain change above recalescence is not instantaneous. Time is as important as temperature. There is a definite grain for a definite temperature. Assuming a 1700 deg. F. grain steel; it will take more time to refine such a grain down to a 1450 deg. F. grain than to a 1600 deg. F. grain.

This brings us back to the original premises: The lowest possible temperature is the best temperature.

In all cases the grain mentioned is the MACROGRAIN.

WHAT OUR READERS THINK AND DO

SOME HANDY HINTS

By Fred Horner

The first scheme is that depicted at A. The illustration shows the use of a dog on an arbor, and this idea is very useful under certain conditions, such as where the work is too delicate to stand hard forcing, or the bore is a trifle too large to give a good driving fit on the arbor. Provided the work has arms or holes through which the tail of a dog may be passed, the latter can be gripped on to the mandrel (with strips of brass or copper for protection) and applied to carry the work round as depicted.

Spot Marking

The second hint is shown at B. This illustrates the marking of spots on opposite sides of round work.

There are many ways of getting locations at exact opposite sides of a shaft. The marking may be done with vee blocks and surface-gauge, or in the lathe, or with one of the special double centering punches. As an emergency dodge, in the absence of all these facilities, it is possible to secure indications by means of a toolmaker's clamp, gripping it lightly upon the shaft and moving it through, with a slight motion sufficient to make bright spots that may be centerpopped. Chalk or whiting can be applied to the shaft first if preferred. The same method may be pursued with a slide gauge, or even a pair of ordinary calipers if passed over the shaft carefully.

The Third Idea

The last idea, shown at C, is a dodge for setting and maintaining a thin washer square on an ordinary arbor. A toolmaker's clamp is gripped on the arbor behind the washer, as seen in the face view, so that it can be noted whether the washer is square across. The clamp backs up and sustains the washer against the pressure of the facing tool. This hint is necessary, because the bore of a thin washer is too short to ensure locating the work square upon the arbor.

THE MACHINING ALLOWANCE

By G. Blake

In these days of mass production and the consequent cutting down of all unnecessary expense, some firms are inclined to err on the allowance for machining on castings, stampings, forgings, etc. In many cases there is not sufficient metal left for machining up, with the result that the saving in weight and cost of metal is very small compared with the cost and upkeep of tools. For instance, the cost of tool grinding is far higher than it should be on account of the scanty amount of metal taken off in the machining. As the tool is only taking off the black skin it very soon puts a dull edge on the best high-speed steel tools. When the allowance is increased, i.e., more metal left on to be machined, the tool stands up better, requires less grinding, and lasts longer, and above all makes a better finish.

Of course where there is a pickling and sand blasting plant the allowance can be cut down somewhat, but the difference is so small that it is of no account in the final cost of the job. The pickling and sand blasting plant saves trouble in the way of tools, and it is a matter of wonder to the writer why so few firms are in possession of such an outfit.

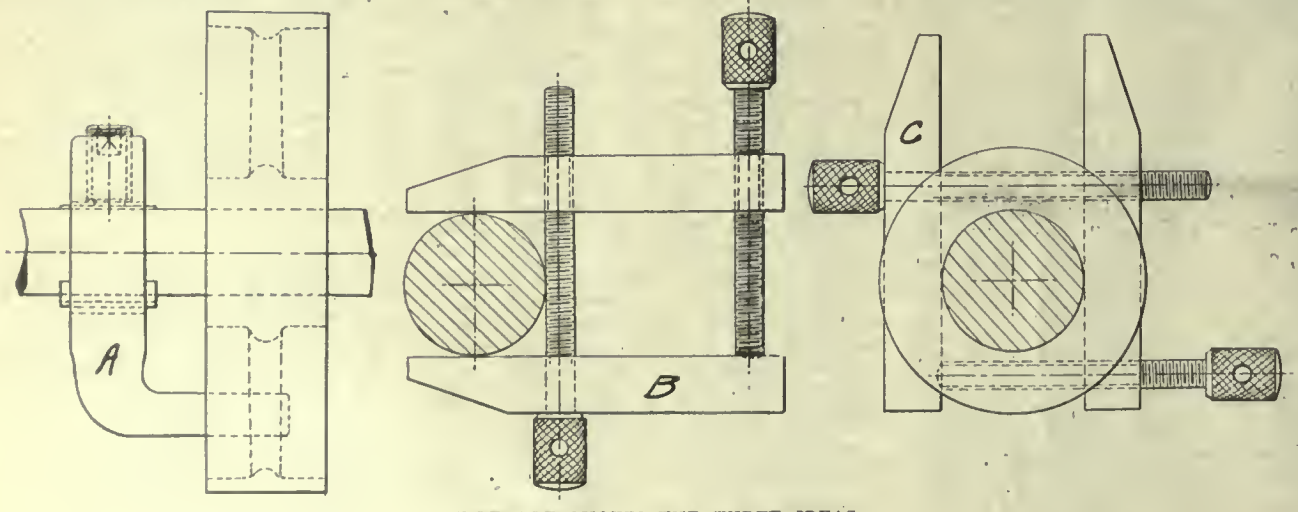
Another point brought before the writer's notice some time ago in the motor trade was the number of small forgings, castings, and hot stampings having cored holes which might well have been left solid as it cost more to open the holes out to size than if they had been solid. This was on account of extra drill and cutter grinding involved.

Another point is the normalizing and annealing of all castings, forgings, stampings, etc. Much can be done in this way to overcome machining costs. Of course this applies more to the small firms as most of the large concerns have their own foundry, forges and drop-stamping department. With small firms it is very essential to insist that all castings, forgings, and stampings supplied from outside makes be thoroughly annealed. In some cases a Brinell test is misleading as very often hard spots are encountered in the machining.

KEEPING THE PLANER BUSY

By Donald H. Hampson.

Machine shops that have planers over thirty-inch frequently find that it is hard to keep them busy more than a quarter of the time. These shops know the facilities of the other shops in the region and they know the requirements of the manufacturing plants in the same territory from this knowledge, they can see no way to keep the planer busier than it is. To stand idle three-fourths of the time is to have



HERE ARE SHOWN THE THREE IDEAS

so much capital idle — not to speak of the room the planer takes up. An idle planer invariably becomes the target of all the odds and ends conceivable, so that when a job does come along it takes a machinist and the floor boy about an hour to dig away the debris.

The printing industry offers work for idle planers in all well populated districts. Printers do not go around hunting machinists to do planer work — the machinists have got to solicit the work, in fact, they have got to call the printers' attention to the need of having the work done. Once the need is shown, the printer will consent quickly enough. There was a time when printers were the most forlorn and run down business people on the list—and this accounts for the presence of vast quantities of second-hand machinery in their plants that needs repairs. But thanks to the Standard Cost System and the Ben Franklin Clubs, the printing industry is on a well paying basis to-day and printers' credit is good at the banks. When it comes to figuring costs on a job, printers are ten years in advance of most machine shops—their "Taylor-White" systems go right down to the two-man establishments and show them everything exactly to a penny.

Returning to planer work. Job presses, also called "platen presses," have two cast iron plates flat on one side and ribbed on the other like a surface plate. Between these two flat surfaces the printing is done. In time the surfaces get worn so that to get an even impression on the "low" spots, the pressman must stop and paper up by trial amounts to turn out good work. The amount of time he spends in a week on such tinkering would pay for the re-planing of the two castings.

The same is true of cylinder presses. Oftentimes the re-planing of the bed of a cylinder press, including a cut over the ways, will make an old press do work almost as good as a new one. These castings may be as large as 40 in. x 60 in. and weigh a thousand pounds, whereas the job press castings are found as small as 10 in. x 12 in., and of only 50 pounds weight.

Paper cutting machines also depend upon the planer work for the accuracy of the product they turn out. The table of the machine is a flat casting with light ribs beneath; it gets some wear and the seasoning of time coupled with standing on uneven floors frequently get them an eighth of an inch out. There is a slot about an inch wide and the full length which guides what is known as the "back gauge" (a part corresponding to the gauge on a sheet metal squaring shears.) This slot gets badly worn; in that condition it is safe to say that it costs the average printer a dollar a week for spoiled work and time spent in dickering with it. Several other parts subject to wear are planer parts.

Then the proof presses come in for a share of attention. These are of two types—one in which a cylinder travels (rolls) along a track at a fixed distance from a planed flat cast iron plate and the other, the old-fashioned Washington hand press, which has two plates similar to a job press and which are caused to approach each other by hand operation, giving the impression in that way. Both types of proof presses are used in some cases for actual printing of commercial work as well as for proving (testing) cuts, advertising matter, set up pages, etc. The proof press must be more accurate than the power presses or their test of the work is void. The worn or bruised plates require a light cut over them to become as good as new.

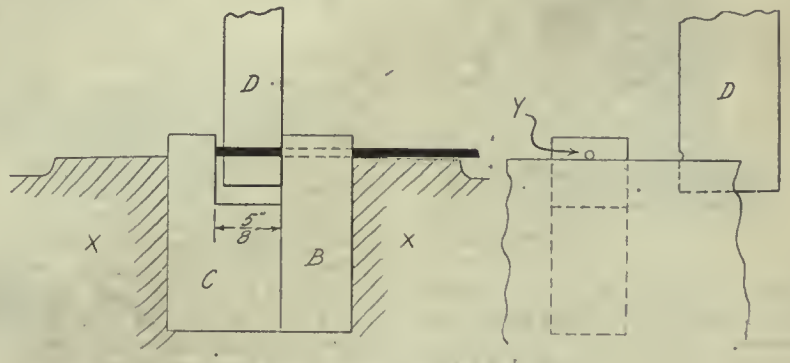
The above mentioned are the most common examples of planer work to be secured in printing offices. Others might be mentioned according to the extent of the equipment. In many cases there is other work that must be done along with the planer cutting, in others the newly planed surface with a little adjusting will suffice. It is doubtful if any printer would refuse to have such repairs made after his attention had been called to their need and to the shop's facilities for handling the work.

A visit to the shop of any manufacturer of presses or folders or cutters or other printers' equipment will show at once the pre-eminence of the planer as a machine tool on such work, and if any shop with idle planers is within reasonable distance of one of these plants, they have only to qualify to obtain plenty of extra work, for with planers at $8,000 and up, they are scarce even with the shops that have ample capital.

SIMPLE PIN CUTTER

By Tyke

Having received an order for one thousand small pins ⅝ of an inch long and .068 inch in diameter, to be made of drill rod, the question as to how these were to be cut off accurately, quickly, and with reasonably square ends, was gone into. After a little consideration the following method was adopted, which gave every satisfaction as to accuracy, and proved to be exceedingly cheap and rapid. The accompanying sketch is virtually self-explanatory, XX being the jaws of the shaper vise, B a tool steel block drilled a few thousandths larger than the drill rod used, and hardened at the drilled end only. C is a machine steel block with a step ⅝ x ⅝ inch milled at one end. D is a tool steel tool grooved as shown in order to eliminate producing a flat on one side of the wire when shearing. This tool was given the merest suggestion of clearance and suitably hardened. The entire device was now ready to use; C and B were firmly held in the shaper vise, as shown, and the tool properly located in the caliper box, barely touching the tool steel block B. A length of drill rod was inserted in the hole at Y and advanced untitl it touched the opposite face of the piece C. The stroke was set at 3 inches and the speed about 60 per minute. The whole thousand pins were cut off in twenty minutes and the tool was good for several thousand more. This simple method more than paid for itself, and with slight modifications could be made adjustable, such as a screw stop in C and different size holes in B, thus taking care of larger or smaller pins of varying lengths.



GENERAL VIEW OF THE PIN CUTTER.

HINTS ON USING NEW TOOLS

By G. Blake

To my mind these are precautions which should be observed in using new tools such as drills, reamers, broaches, etc. Many tools are broken through the operator's ignorance and neglect. A new drill, reamer or broach has been drawn from the tool store and smashed in a few seconds, especially in cold weather. Most tools give best results when slightly warmed.

Say in the case of a new drill, the operator will fix it in the socket, start up the machine, and put the feed on right away. The result is that the sudden shock on the new drill causes the drill to break. When using new drills over ½ inch diameter, reamers or broaches, the writer recommends that they be warmed by dipping in hot oil. In the case of drills, you should use a light feed for the first few holes.

The same applies to broaches, which, if treated in the above manner, will amply repay the trouble and time spent. Of course this is not necessary in very hot weather, but it is essential in cold climates and during frosts. It has been observed during very severe frosts that machine tools, etc, are very easily broken.

DEVELOPMENTS IN SHOP EQUIPMENT

COAL OIL LAMPS

The Standard Meter Co., Ltd., 10 Morrow Ave., Toronto, Canada, have placed on the market a very interesting line of lamps which are described herewith. At Fig. 1 is shown what is known as the Monitor high power coal oil brazing lamp. This lamp is used for brazing

FIG. 1—SHOWING BRAZING LAMP.

and work of similar nature on a large scale and can be used in any position. It is said to be both portable and powerful. They are made in 2, 4, and 5 pint sizes.

The next type of lamp shown at Fig. 2 is known as the Monitor high power coal oil blow lamp. This style of lamp is both wind and rain proof and is used extensively by millrights, plumbers,

FIG. 2—SHOWING BLOW LAMP.

electricians and hot water engineers. This lamp is made in 2-3 pint, 1 pint, and 2 pint sizes.

Another type of lamp carried by this concern is known as the Petropark high power inverted incandescent coal oil lamp. The latter style lamp is used as portable light for country railroad stations, farm buildings, fair grounds, large workshops, wharves and other innumerable places where portable lights are desired.

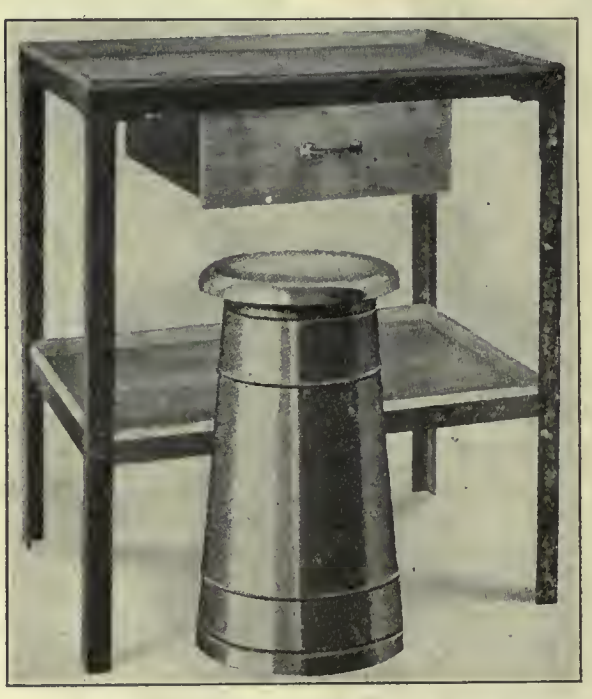
TOOL STANDS, RACKS AND STOOLS

The old days when a manager would discharge a man for sitting down to his work have passed. It has been proved that for certain classes of work the workman can become more effective by sitting, and the same holds good insomuch that men are no longer allowed to waste time running all over the shop to find tools. Nowadays tool stands, drawers and benches are always handy to the various machines, or at least such is the case in the real up-to-the-minute plants.

The National Engineering Co., Ltd., Sarnia, Canada, are firm believers in all the above statements and to follow out their belief have placed on the market a varied line of time savers. These include tool stands of various nature and sizes, some being supplied with drawers and some without. They also market an all steel storage rack which can be built in any number of sections and combinations for use against a wall, or placed back to back. Such racks are especially useful in warehouses, or in the cut off department.

In addition to the above mentioned lines they make a shop stool of novel design. This stool is depicted in the illustration standing alongside one of the tool stands as made by this concern. The stool is so simple, yet efficient, that it requires no explanation except that it is made in three heights, 24-ins., 27-ins. and 30-ins.

The A. R. Williams Machinery Co., Toronto, are handling this line and will be pleased to give all information regarding the same upon application.



VIEW OF THE STOOL AND THE TOOL STAND.

METAL CUTTING MACHINE

The Yoder Co., Cleveland, Ohio, have issued a machine for use in cutting sheet metal into strips suitable for various purposes. It is claimed that this equipment provides a rapid means of performing the operation and that the work is done in a way that insures parallelism of the edges. Machines of this type

are made in several sizes to accommodate various widths and thicknesses of metal.

TURRET CHUCK

The Scully-Jones & Co., 647 Railway Exchange Building, Chicago, Ill., have placed on the market what is known as a "Wear-ever" turret chuck. This chuck is of the same general construction as other chucks of this company's manufacture, but is designed to hold square-end tap shanks or other tools with shanks of the same form. Various sizes of chucks are made to fit different diameters of tap shanks, and standard bushings to be furnished to allow a chuck to be used in large turret holes.

SHEET TINNING MACHINE

The Aetna Foundry & Machine Co., Warren, Ohio, have placed on the market a machine designed for use in tinning heavy sheets used in the manufacture of milk-can bodies. There are three pairs of rolls, the lower pair acting as feed-rolls, the second pair, which run in a bath of tin, acting as spreaders, and the upper pair of rolls, which run in an oil bath, removing the excess tin, and leaving the sheets with the desired coating and finish.

AIR OPERATED CHUCKS

The Logansport Machine Co., Logansport, Inc., have issued a new line of air chucks with a duplex control mechanism which allows them to be used on double spindle turret lathes built by the Jones & Lamson Machine Co., of Springfield, Vt. Frank G. Payson Co., 9 S. Clinton St., Chicago, Ill., is the selling agent.

PORTABLE PROJECTOR

The Graphoscope Development Co., 50 E. 42nd St., New York City, have issued a moving picture apparatus especially designed for the use of salesmen. This complete unit, ready for operation, is packed in a case of about the same size as an ordinary suitcase. It is equipped with a motor drive and is of simple construction. The machine uses standard films and will project a picture 10 feet square at a distance of 35 feet.

U. S. SUB-PRESS

The U.S. Tool Company, of Newark, N.J., are now manufacturing sub-presses for various classes of stamped work. Stock sizes with platens of 2 by 3 inches and 6 x 8 inches are carried, and special sizes for particular work may be obtained.

STANDARDIZATION OF MATERIALS

For the first time in Australia, systematic and comprehensive steps are being taken for the standardization of various materials used in industry. This question was taken up some time ago, quotes the "Commonwealth Engineer," by the Institute of Science and Industry, and the first Australian standard specification for the Commonwealth, relating to steel, used for structural purposes such as angles, tees, beams and channels, has now been published. This is the first of a number of Australian standard specifications which will be issued by the institute, which has already brought into line the views of both manufacturers and users as to uniform standards for not only structural steel, but also of railway rails and fishplates and tramway rails and fishplates. Standard specifications for the two latter will be published by the institute shortly.

AIR PLANER

The Turbine Air Tool Co., 710 Huron Road, Cleveland, Ohio, have placed on the market a line of air planers which are adapted for such uses as shaving telegraph poles, telephone poles, etc., etc. They are also used for railroad tie making, pile peeling, removing bark from logs for foundation building, and general dock, wharf, and dam building. There are of course many other uses for such a type of tool but let us go into a description of the same.

As can be noted light weight has been considered. The device has only thirteen primary parts, and has no reciprocal parts. The only wearing portions are the ball bearings and the only parts requiring replacement are the knives and ball bearings. The work of making these replacements is exceedingly simple.

The power used is compressed air, and the speed is from nothing to 12,000 r.p.m. at the knife. The model P

FIG. 1—SHOWING MODEL P PLANER.

shown at Fig. 1 should be operated from an air compressor with 100 pounds pressure, giving 45 cubic feet of free air per minute.

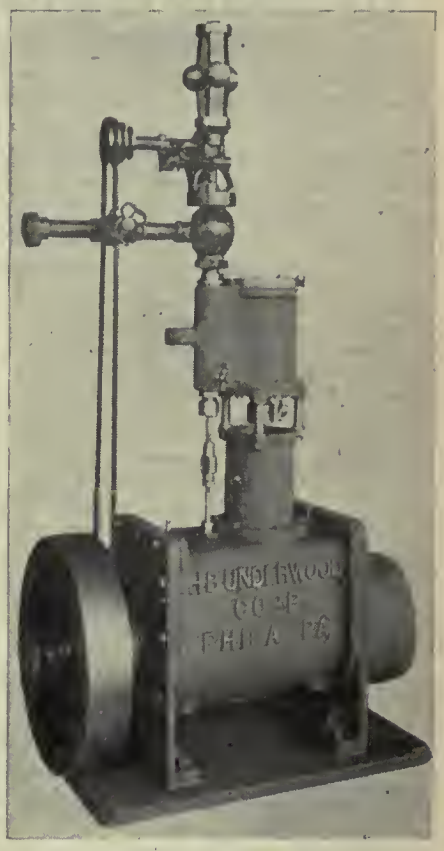
The cost of maintenance is said to be

FIG. 2—ILLUSTRATING MODEL D.

negligible and the machine is easily kept in working order. The model D shown at Fig. 2 is similar to Fig. 1, with the exception that it is designed primarily for work on flat surfaces.

AIR OR STEAM ENGINE

The H. B. Underwood & Co., 1015-1025 Hamilton Street, Philadelphia, Pa., have placed on the market what are



GENERAL VIEW OF THE ENGINE.

known as their 3 and 5 h.p. steam or air engines. These engines are built in the two sizes above mentioned, and the illustration herewith gives one a good idea of their general appearance. They are used and designed for driving portable tools such as boring bars, valve seat rotary planers, drilling machines, etc., and are constructed to use either compressed air or steam.

All working parts are enclosed in an oil tight case, which is formed in the base of the engine, making it dust proof, and reducing wear to a minimum. The cylinder of the 3 h.p. engine is 3½-inches diameter and of the 5 h.p., 4½-inches diameter, both engines having 3 1-2-inch stroke. The design of the piston valve used is said to reduce friction and wear to a minimum.

The crankshaft is a solid forging-finished 1½-inches diameter. The engine is well balanced, uses 70 to 125 pound pressure, and runs at 250 r.p.m. This engine should particularly interest railroad shops.

The floor space required is 12-in.x 21-inches, and the height from base to extreme top of governor 46 inches. The net weight is 270 pounds.

Steel Market Still High

THE premium market may crack, but the steel market in general is not on the skids.

The premium market is a peculiar sort of a creation. If you desire you can refer to the operators in it as a lot of gougers, but if you take the trouble to sit back and think it over a bit, you may find that the frenzied bidding that was done by some lines of industry for available material had much to do with the creation and the upkeep of the premium market.

The automobile business has done more than any other line to build up a premium market in sheets. There were stove makers who, months ago, parted with their stocks of sheets, letting car builders have them at prices that were larger than the profits that would have been made by putting these sheets into stoves.

When any man has a group of buyers around him bidding for something he has for sale, the chances are ten to one that the price is going to go up. The buyers made the premium market in the first place, and the mills are showing no tendency to let the profitable thing die on their hands as long as they can pulmotor an ounce of steam into its system.

The Canadian trade stands to benefit by a better supply of steel coming from the mills of United States. Stocks are low, as buying has been done on a very limited scale.

Buyers may get some relief shortly. It is coming to them that any reduction shall be passed on to them at once, for most of them have been buying from the premium mills and paying the long price.

Heat Treating of Steel

THE convention and exhibition of Steel Treaters held during the week of Sept. 14 to 18 at Philadelphia marks an important step in metallurgical progress. It is only a matter of two years since this organization came into being, yet in that short time they have obtained a membership in the neighborhood of 4,000, and local chapters are now to be found in practically all cities interested in the treatment of steel.

The need of development in the steel treating industry has been felt for some time, and the society is doing a splendid work in this regard. The demand for quality steel is now a common one, and steel treatment is well known to bring out the best qualities in the steel.

The heat treatment of steel is no longer considered a fad. It is a recognized science. The eye is not sufficient these days to judge or guess at the correct heat. Up-to-the-minute apparatus is employed, such as optical pyrometers and testing equipment of all kinds. The age of scientific steel treatment is here to stay.

Toronto has so far the honor of being the only Canadian Chapter, but in the next few years we will, no doubt, see other Canadian branches arising.

The Strike of Iron Workers

THE argument has been put forward many times that union workmen are out for the benefit of all the workers.

The strength of concerted action is supposed to help the little man who otherwise would have a hard time going up against some of the large combinations of capital and talent.

Just now iron workers in Toronto are striking for recognition of their union and $1 per hour as their rate of wages. They have left several large jobs, and are already tieing up the work.

The secretary of the Building Trades Council has this remark:—

> "The serious feature of it is that the roofs of many structures will not be on by the time winter sets in if the strike is allowed to continue. No inside work could be done during the winter."

That is plain enough. The strike of the steel workers for an increased wage and recognition of their own union may mean that tradesmen in half a dozen other lines shall be kept from securing employment on these buildings during the winter months.

This is a point where unions have failed to show the consideration for others that one might reasonably expect.

Do Boilers in Sinking Ships Explode?

DID you ever read about the boilers in a sinking ship exploding? The average man has neither been shipwrecked, nor has he been gazing on the boilers of a sinking ship to see just what does happen. And further, most people who happen to have gone down, lingering in the vicinity of the boiler in a sinking ship, have not returned to make out a report on what really did happen.

Mr. T. H. Fenner, editor of Power House, and a close student of such matters, claims the old theory is all wrong. In a recent issue of his paper he says:—

"In a newspaper report of a recent disaster on the Great Lakes, the statement is made that as the vessel was sinking, the boiler exploded. This is not an unusual statement, but we venture to say it has little but the reporter's imagination to back it up. Is there any good reason why a boiler should explode on a sinking ship? The thoughtless individual usually jumps to the hard-worked explanation of the sudden contraction and lets it go at that. What, then, does this sudden contraction perform? Does the shell contract so much that the pressure is increased beyond the resisting strength of the metal? Most assuredly not. The sudden contraction theory does not hold water. The fact is that the boilers do not explode when the ship is sinking. If they did, it would be of little use trying to salvage sunken steamers, as they would be damaged to such an extent that salvage would be impossible. Of all the steamers sunk by mine and torpedo during the war, were there any cases of boiler explosions unless the boiler shell was actually ruptured by a piece of shell, or other projectile? As a matter of fact, the boilers on steamers sunk and afterwards salvaged are usually found intact and fit for use again. This idea of the boilers on a sinking ship exploding is one that has been fostered by non-technical writers in the daily press, and accepted without question by men who should know better, and who would recognize the error of the statement if they gave the matter a little thought."

Price Tendencies Much Discussed This Week

WHEN the announcement was made from Detroit a few days ago that the Ford Company had cut deeply into the price of cars, the question at once came up: What will the makers of cars in Canada do to meet this?

It creates a very real situation. For some months past the automobile industry in Canada has been doing the great bulk of the buying in the machine tool market. They have been speeding up production, and there has been a market for their cars. There has been a lot of money in the country, and makers were able to pass on increasing costs to the consumer.

To-day the makers of motor cars are not speeding up production. They are making what cars they can sell in the present market. Were they to do otherwise they would be ruined. All that would be necessary to accomplish this would be to go ahead and fill up warehouses and agency branches with high cost cars, and then sell them in a declining market. One automobile maker, discussing the matter with Canadian Machinery this week, stated:

"The move of Henry Ford certainly puts it up to us in such a way that there is no use trying to dodge the issue. We will have to face it. I have no doubt but that our salesmen in the farthest corners of the country were asked that question the first morning the Ford cut was announced: What is your firm going to do about it? You can take it for granted that the makers of cars did not put up prices this year because they wanted to. The buying public were expecting a move in the opposite direction and there is nothing that would have been better for the automobile business. But what happened? We were in a very high market for everything that went into a car, and when we announced an increase in price we did the very same thing that other makers did, acted because our cost sheets pointed the way we must take. It was either a case of lower the cost of the car or get more for it. When this condition came about there was only one thing to do, viz., keep production well in hand with immediate sales.

"Now then, for the lowering of costs in Canada. That is your question, and my reply would be off-hand that if selling prices go down then everything must crack: the steel market, the wages, the dividends, and general commodities. There will undoubtedly be an announcement made in this matter soon, but the bolt—and it is a real bolt—came so suddenly that the situation cannot be figured out in a day or so."

The Implement Manufacturers

Another of the fields that is already feeling the demand for a lower price is the plow shops. As a general thing these places are working a year in advance. That is, they are buying now for what they will make in the last part of 1921 and the first of 1922. Several of these firms have warehouses pretty well filled up with high-cost product, and they are anxious naturally to speed up their sales in order to get the stock out before a lower price becomes recognized by the trade. The implement business recognizes that the rupture that has taken place in the price equilibrium of the automobile market is bound to have an effect on the whole metal working field, especially since Ford has cut into the price of tractors as well as touring cars.

Welcomes the Move

Here is another idea of the president of a firm doing particularly fine work in the mechanical field:

"The move that is taking place now and which was started by Henry Ford, is right. It should have been made a long time ago, and I hope it will spread all through our industrial life. I am not afraid of it in the least, for fundamentally we are sound. The trouble is we have been joking ourselves too long. There are actually people who believe that all that is necessary to have good times is to keep on printing paper money. I sat in at a conference of manufacturers and bankers two days after the signing of the armistice, and we discussed this very thing for hours. At that time I wanted a readjustment and I have never seen anything since to make me change my views. For two years now we have been fooling ourselves. We have been like the squirrel in the cage that chases his tail. It has been higher prices, higher wages, higher prices, higher wages until we have got to the point where there is no stability in anything. We are paying out a lot of money to men and when they go out in the markets to buy they find they have not so very much after all.

"So what have we? On one hand we have the workers and the wage-earners calling for more money, we have the men selling raw materials to us calling for more money, we have the men who are going to build a factory addition calling for more money, and every person who does anything is calling for more money, and in most cases getting it. On the other hand, we have the bankers, who are trying their best to save the credit of the country, working in the opposite direction, trying to keep down credits, and make the amount of business conform to the amount of money we had in circulation. There are too many fine adjustments in connection with economics and finance that we have overlooked, or if we have not overlooked them we have not had the courage to face them. As a result of all this we have the man in business having to get in touch with about two and a half times as much money as he did in 1914 to finance a given volume of trade and to take care of the decreased output of the men in the shop. The thing cannot go on as it is.

"When the war was over we should have done generally what Henry Ford has now set out to do. People were expecting something to happen then. We all knew we had been living on war tension. Men knew they were making war wages, and they expected that they would drop with the close of the war. Men who had put money into war ventures made big returns, and they never expected them to continue after the war. Commodity prices never had a good reason for staying up except for the artificial bolstering that has been put under them. I contended right after the war was the time to take our bumps, and I have never seen anything since then that has caused me to change my mind. I could get the backing of only two men at the conference I mentioned before to such a course. The rest were afraid of that thing they call unrest, and feared the consequences of an effort to let things take their own natural course in the process of readjustment. We were expecting something to happen right after the war, and right after the war was the time when this something should have happened that they are trying to bring about to-day.

"Now it is here, at least to my mind there is nothing more certain than that prices are going to crack. When we get some of the big leaders setting the pace in that direction the movement is on, no matter if it is in United States, because the markets here directly reflect any influence that is set in motion there. As I said before, our firm does not fear the bust, the crack, the explosion, or whatever else you care to call it. It will simply mean that we can get more money, that the money we get will finance more business, and we will be nearer our proper position having regard to the gold standard, and the value of our money in the foreign markets."

MARKET DEVELOPMENTS

Prices Not Tumbling in Steel or Tools

Business Being Placed at To-day's Prices for Six Months to Come —New York Reports That Machine Market There Does Not Look for Improvement Before First of the Year.

TALK of price cutting in the iron, steel and machine tool market finds no reflection in fact. It is safe to presume that the premium steel market is due for a setback, and this may be brought about by the attitude of buyers themselves rather than by any desire on the part of the mills to have cheaper steel. Buyers, by their persistence in bidding for material, have had much to do with keeping the premium mills busy. This is particularly true of the sheet mills.

A pretty good indication of what dealers think of the chances for lower prices can be secured from the attitude of the warehouses. One firm this week, in the face of price lowering talk, placed an order for tonnage that will take care of his business for the next six months; this was in bar iron, which is to-day selling at 5.75 per pound, a record price for this district. This dealer cannot see easier steel prices for some time, and he is willing to back his opinion with his own money.

Machine tool dealers have nothing on which they can announce a lower price. Makers speak of increasing transportation costs of labor increases, and they see no relief in all the things they put into their machines. Some of the schedules are still some weeks behind. The buyers of tools figure that there is more real selling going on now than for months past and from past experience they believe lower prices may come. Dealers say nothing to encourage this view.

The scrap metal market is very dull.. The large buyers are not in the market yet, and until they come trading is going to be confined to small lots.

MACHINE TOOL BUSINESS BELOW NORMAL IN MONTREAL MARKET

Special to CANADIAN MACHINERY.

MONTREAL, Que., Sept. 27—Business appears to be reaching another stage in its history when uncertainty will be the ruling factor, and this will result in a further policy of conservatism in the buying attitude of consumers. This feature has been more or less pronounced during the past year, but the belief that the present is an opportune time for a determined start to be made in peace time adjustment seems to be taking hold of many of those directly associated with industrial enterprises. This trend of thought has been developed in seclusion and will likely be gradually impressed in a more concrete form from now on.

Steel Market Unsteady

While there is no visible evidence to substantiate the statement, the early trend of prices in many steel commodities will probably be in a downward direction. Dealers here are not looking forward to any drastic reduction in prices, but there are very few but what believe that before the close of another month the conditions will warrant a decline on existing quotations. Observations by dealers' representatives, who have been in the States recently, state that the mill congestion is much less marked at present, owing to the better facilities of the railroads and the improved movement of freight of every description. This condition has enabled producers to operate to increased advantage and the greater output will, no doubt, be felt in trade circles in the near future. The sheet situation is far from normal, but the lessening activity of the motor industry has created an increased supply of sheets that has materially assisted in bringing relief in other directions, notably to stove and car manufacturers. Consumers, apparently, are better pleased with the way material is coming to hand, and dealers are being freed from the necessity of urging heavier shipments from the mills. This may be due to several causes, among which may be mentioned a visible decline of general industrial activity, and the fact that builders and manufacturers are assuming a waiting attitude in the expectation that prices are coming down. Such a situation may develop, but there is little to support a belief that any such movement will affect, to any great extent, the present prevailing prices. It is true that production is on the increase, but this is primarily due to the more regular operation of the mills, the cost of producing being generally maintained by the high character of wages.

Machine Tools Quieter

Despite the occasional announcement that machine tool business is good, the general impression gathered from reports from dealers is to the effect that present activity, while showing slight improvement over that of the midsummer months, is, nevertheless, below the normal for this period of the year. No one branch of industry seems to be responsible for this condition as orders are widely distributed and general in character. The aggregate business, however, is reasonably well maintained by the steady supply business that is practically unaffected by the noticeable trend to industrial curtailment. Even here, however, the buying is of a conservative nature and it would not be surprising to see lighter buying in the near future.

Metals Unsteady

The metal market has not been featured by any outstanding development but has been subject to slight fluctuations in price quotations. Coppers have been moving normally with prices well maintained, conditions tending to weaker quotations. Tin has shown a little unsteadiness owing to the uncertain industrial conditions in England, but apart from disturbing the even tone of the local market, the English situation has influenced prices here but slightly. Present quotations are on the nominal basis of 54 cents per lb. Spelter is steady at 10¾ cents, while lead is easier at 9

cents per lb. Antimony is in good demand at 9½ cents per lb.

Scrap Continues Quiet

"We are here for the sake of appearances. Trade is very quiet and the buying policy of the consumer is not a stimulant to greater business. The market is not strong, neither is it weak, but it is very quiet. Price is little inducement in making sales. Material is bought only when it is needed." This statement outlines the old material situation and is a good indication of the dull state of the situation generally. Foundry iron and steel scraps are the heaviest movers.

CAN SEE NO CRACK IN PRICES HERE

Some Steel Dealers Are Buying at Today's Prices For Six Months to Come

TORONTO.—The talk of price cutting is something that one hears much of in the markets to-day, but signs to show where it has actually visited the steel, iron and machinery market are lacking. It might be expected that steel warehouses that carry on a merchant business would be first to respond to price reductions, were any seriously in sight. No evidence of such a move can be found.

Machinery dealers claim that they have heard nothing from their principals, and until they do there is absolutely no chance of them making any reductions, as they for the most part simply sell the machines at a fixed rate of profit.

Some of the dealers in the city have sold a lot of machine tools during the past week. There are no large orders in the market, but a number of smaller deals have been put through. The trade does not expect much from the automobile industry just now, realizing that they are not likely to go ahead with much rapidity in face of the recent price slashing in certain makes of cars.

"Our deliveries are coming through very well," said one dealer, "but we are still some weeks behind in many lines. I can't see where prices are going to crack, although I will admit there is more or less of a demand for such a move on the part of the buyers. I do not see any reduction yet in iron, steel or wages, nor yet in transportation costs. The material the makers are working out now is all high price stuff, and I cannot see, unless something very unexpected happens, why or how we can have cheaper machine tools for some time to come."

Other dealers hold views along this line. They all admit that it would be a nice thing to be authorized to announce a 10 or 20 per cent. reduction, but they are all equally emphatic in stating that they do not see how it can come about yet.

POINTS IN WEEK'S MARKETING NOTES

Some of the independent steel producers in the Pittsburgh district admit that they expect their prices to fall.

—

It is claimed that most of the U.S. automobiles that have been placed on the market at high prices have been manufactured from steel that was bought at the March 21, 1919, War Board schedule, and that the prices paid for the steel did not warrant the prices asked for cars.

—

There is very little buying being done in the United States steel markets. Deliveries have been quite rapid in the last few weeks and the amount of steel piled at the mills has been rapidly decreasing.

—

The talk of price cutting in the steel, iron or machine tool markets finds no reflection in actual reduction. Dealers in Toronto say they have no word from their principals in regard to price changes.

—

One Toronto warehousing firm this week placed orders at present prices for their supply of bar iron for the next six months, showing that they do not anticipate any reduction in price during that period.

—

The scrap metal market in Canada is a still and uninteresting affair. Larger buyers such as the steel mills are not in the market and little improvement is looked for until there is something definite done in the way of stabilizing the prices.

The Steel Market

Here is the opinion of one of the leading steel merchants in Toronto, and it covers the case pretty well:

'We look to see some of the premium prices taken off first, and at the same time it is likely that prices of the Steel Corporation will go up. Of course I have no knowledge of the affairs of the Steel Corporation, but I have been through the steel country lately and that seems to be the generally accepted opinion there. Now we are not looking for a drop in prices of steel for some months. We may be wrong, but I have gone pretty carefully over the situation, looking to such things as the supply of coal and iron ore, and the closing in of the shipping situation on the lakes. These are all factors that have a great deal to do with the output for the coming six months or a year for that matter. I cannot see anything to make me believe that the prices of steel are going to come down."

Backing His Beliefs

"Have you enough confidence in that prediction to buy for some months to come?" we asked.

"I have, and only this week we placed orders for a large tonnage of bars from a Canadian mill, covering deliveries for the next six months. The price paid is the price right now, and it means that we will still have to sell bar iron and steel at 5.75c per pound, which is the highest figure that we have ever experienced in a good many years of business in this city. We are willing to take a chance on our guess being right. If the market cracks, as people say, we will have an interesting time of it, but the only thing that can crack it is an over-production, and do you see it coming? What is more, it does not pay us to pay too much attention to every little price flurry. We are dealing in the most requisite thing possible, steel, and it will not be possible in years to get steel at anything like the prices that were prevailing before the war."

There is a fair tonnage of premium mills sheets in some of the warehouses. These were taken in at a high price, but there is no intention on the part of the warehouses to reduce the price. "Were we to start that we would at once defeat our own object, and what is more we are not going to trim the price. We paid a lot of money for them and we must sell on the basis of cost. The market is empty of these lines and we have no fear about getting rid of them."

A Weak Market

The scrap metal market is decidedly weak. The interests relied on to keep up the buying in large quantities are not in the market, nor do they show any inclination to come in. Copper is not moving in any degree. "Until prices get down to something definite we do not look for an improvement," is the way one dealer sized up the situation.

NO IMPROVEMENT LOOKED FOR IN 1920

New York Machine Tool Market Is Quiet and Nothing Is in Sight to Revive It

Special to CANADIAN MACHINERY.

NEW YORK, Sept. 30—There has been no change in the machine-tool situation. There is very little inquiry and orders are few. Except for a fair amount of railroad buying at Chicago, the demand for machine shop equipment over the entire United States is quieter than it has been since 1913-14. Some plants are letting men go and are reducing operations.

It is apparent that there will be no general resumption of machine-tool buying until industrial conditions are on a more stable basis. The deflation of prices, which has been in progress for some months in certain lines, and which within the past week has hit the automobile industry, must progress to a

point where buyers will have more confidence.

The announcement of the Ford Motor Co. of a reduction of automobile prices to the pre-war basis is the most far-reaching single item in the present industrial situation. This reduction has been followed by similar cuts by the Franklin and Crow-Elkhart companies and undoubtedly others will follow suit soon. It was the activity in the automobile trade which brought about general business prosperity in 1919, and it was the slump in automobile demand, caused largely by tight money, which has brought about the present inactive conditions. This is particularly true with relation to machine tools. When a considerable number of automobile manufacturers have reduced their prices the way may be paved for a resumption of automobile buying, followed by the same business boom which resulted from the automobile buying fever last year.

Many automobile manufacturers had plans in mind for further expansion, and a few new plants were in course of construction, when the slump hit the automobile trade. Wholesale cancellations of machine tools, which followed this slump, have hit the machine-tool industry hard. It is quite possible that resumption of automobile activity, together with increasing railroad buying, will restore prosperous conditions to the tool industry next year. Few expect better business conditions before January 1.

PREMIUM MILLS MAY COME DOWN BUT NO GREAT REDUCTION IN SIGHT

Special to CANADIAN MACHINERY.

PITTSBURGH, September 30.—Independent steel producers make considerably less effort than formerly to conceal the fact that they expect steel prices to decline. A common prediction now is that prices will not go below the Steel Corporation level. As no one had predicted that they would the statement is not particularly important, except as a definite admission of an abandonment of the hopes independents had entertained from time to time that the Steel Corporation would advance its prices. The main question now is one of time, when it will be that the independent steel prices will drop. Thus far they have not declined to any really noticeable extent, for the decrease in premiums for particularly prompt shipment that has been in progress at intervals for three months or more does not represent a general market decline. Naturally, in keeping with traditions, the aim of independent mills is to hold their prices up as long as they have much contract business on their books, as to reduce prices would be to encourage cancellations and suspensions of shipment.

The Automobile Declines

Up to date, Ford, Franklin and Crow-Elkhart have announced reductions in the prices of their cars, from 15 to 30 per cent. In some quarters these reductions, doubtless to be followed by other automobile makers, are regarded as containing a challenge to the steel industry to reduce its prices. The steel industry, however, shows some indisposition to admit that any challenge of this sort is necessarily implied. They point out that during the past nine months, or say since the first of the year, the automobile makers have received steel at a very wide range of prices. In the aggregate, by far the major part was at the Industrial Board prices, and a relatively small part was at very fancy prices. It is asserted that automobile prices of late have been in relation with the highest priced steel, constituting the smallest tonnage, rather than in relation with the lowest priced steel, constituting by far the bulk of the tonnage. The fanciest prices were made by the automobile industry, seeking additional tonnages to supplement deliveries due on contract, and practically disappeared when that particular trade stopped buying.

In view of the fact that the sharp price advances in steel products early this year were due in great part to the eager and extravagant bidding of the automobile industry, and were recognized at the time as being caused chiefly by that industry, when other consumers who wanted steel were unable or unwilling to bid fancy prices, it might be considered natural enough that now the automobile industry should be able to exert an influence in the opposite direction, and produce low prices as it formerly produced high prices. One difficulty, however, is that the automobile industry does not really take any large part of the steel output, and another is that the trade has been so sudden in its recent cancellations of orders and instructions to suspend shipments that its contracts cannot well be set at a high valuation, excepting, of course, one or more large makers who are good in living up to contracts.

Heavy Deliveries of Steel

The great increase in steel deliveries that has occurred in the past few weeks does not seem to be rated as high as it deserves to be in constituting a market factor. The stagnation in new buying is properly attributable chiefly to this increase in deliveries. It should be noted, first, that the production of steel in August was seven per cent. more than the production in July, while the production August 1 to date has been well in excess of output in the same length of time prior to August 1. Next it must be noted that up to about August 1, and beginning in April, the steel mills were stocking steel, on account of car shortage. Since about the beginning of August they have been moving their stocks, and the highest estimate is that one-third of the stocks remain, while the lowest estimate is that practically nothing remains of the stocks. Thus the stocks have been moved at a much greater rate than that by which they accumulated, and the production itself, also moved, has been greater than formerly. Obviously the tonnages of steel received by jobbers and manufacturing consumers have been much greater in the past few weeks than in July and preceding months. This change would in itself be amply sufficient to account for the stagnant market.

It is the common view, however, that there is a decrease in consumption of steel, with further decreases in prospect, and thus no one seems to expect the market to recover. The common view is that prices will have to go through a course of liquidation, so that the only questions are when the readjustment will occur and how far prices will drop.

As to decreases in consumption, there is the automobile industry, which is consuming less than one-half as much steel as it did at the top point, and then there is the showing made by the fabricating shops, the report of the Bridge Builders' and Structural Society showing bookings of fabricated steel contracts in August equal to 40 per cent. of the fabricating capacity, against 50 per cent. for July and an average of 72 per cent. for the first six months of the year. Again, there is the case of the railroads, which are buying but little now, and are hardly likely to be in the market again in the near future. In the first eight months of the year about 65,000 freight cars were ordered by the railroads and industrial concerns, but there is no likelihood that the last four months of the year will add much more business.

Steel Prices

The independent plate market is quotable at about 3.25c. There are rumors of lower prices being done, but these lack positive confirmation. Merchant steel bars can generally be bought at 3c by buyers with regular mill connections, and mills that are quoting higher prices, up to 3.50c or more are probably getting little, if any, business. Shapes are 3.10c, but with scarcely any buying. Black and galvanized sheets show a declining tendency, but are very difficult to obtain for early delivery at any price. A fair average of the independent sheet market is 7c to 7.50c for black, 8.75c for galvanized, 5.25c for 5.50c for the heavier gauges of blue annealed, say 12 and heavier, with 5.75c base for 16 gauge.

The Steel Corporation prices, which are going to be more and more in evidence, are: Bars, 2.35c; shapes, 2.45c; plates, 2.65; blue annealed sheets, 3.55c; black sheets, 4.35c; galvanized sheets,

5.70c. These apply only to the domestic market.

Pig Iron

The local pig iron market is quotable unchanged simply because nothing has occurred, and the "market" must be given at the levels at which business was last done, $50 for foundry and malleable, and $48.50 for Bessemer and basic, f.o.b. valley furnaces. Lower prices might be quoted even now if there were any inquiry, but there is none. Pittsburgh foundries do not even buy southern iron, which can be had at $2.36 less, delivered Pittsburgh, than valley iron.

PIG IRON TRADE

The pig iron market continues firm. Orders on producers books equal five months' output of furnaces. Shipments are moving freely. Resale iron is more plentiful on the market at Philadelphia owing to better railroad conditions. Enough basic has been sold to establish the price at $50 eastern Pennsylvania, or around $52.50 delivered. More than 1,000 tons of malleable was bought under $52, which appears exceptional as malleable has been strong and scarce.

The market is very quiet in Chicago. Cancellation of automobile castings has affected the melters in Michigan and Indiana, who are booked up with automobile business.

Sales of pig iron at Boston have been small, mostly limited to prompt shipment. The price for 1.75 to 2.25 per cent. silicon iron is quoted at $51; $52.25 for 2.25 to 2.75 silicon, and $55 for 2.24 to 3.25 silicon. One Tennessee furnace was closed down during the week on account of lack of coke.

New York reports shipments of pig iron have increased owing to improved railroad conditions. In this connection, Buffalo foundry iron at $48 Buffalo for the 1.75 to 2.25 silicon grade. Some Central Pennsylvania foundry has been sold for prompt shipment during the past week at $50 furnace for 2.25 to 2.75 silicon.

The market at Pittsburgh is extremely dull, consumers showing practically no interest. Furnaces are well booked for the remainder of the year. Better car supply and larger deliveries of fuel have increased the pig iron output somewhat and the Carnegie Steel Co. is operating 41 of its 59 furnaces, which is an increase of one stack over last week.

Basic is quoted at $50 on the Buffalo market. All the sales last week were for last half delivery.

The tone of the pig iron market at St. Louis is less favorable than recently. In the past few weeks a considerable tonnage has accumulated in the yards of the southern furnaces. Prices have not changed excepting that several makers who had been quoting $45 for No. 2 southern (1.75 to 2.25 silicon) have gone to $42, there being plenty of iron offered at that figure.

U.S. SCRAP METAL

CHICAGO reports that the decline in quotations on iron and steel scrap continues steadily on the market. Consumers are avoiding purchases as long as possible to reduce their reserves to the lowest point and avoid losses by further decline.

On the whole the market in New York is quiet. There has been a slightly improved demand and as a result an advance of .50 cents in turnings, clean cast borings, and wrought pipe of special dimensions.

Considerable scrap has been sold at Philadelphia following the purchase by one firm of 5,000 tons at $27 delivered about ten days ago. There is a scarcity of rerolling rails.

The American Steel & Wire Co., Worcester, Mass., has come into the market again at Boston, for heavy melting steel. As high as $23 at shipping point is being offered for sizable lots of heavy melting steel.

The market at Pittsburgh is very quiet, with no inquiries or new business. Heavy melting and No. 2 railroad wrought is somewhat firmer.

The demand for all kinds of scrap is heavy for delivery in from one to two months, at Buffalo. There is a strong demand for machine shop turnings and cast iron borings, as well as heavy melting steel. Railroad conditions are much better.

The recent buying movement in the Detroit market has subsided. Much scrap is available, but the higher prices developed by the movement continue to prevail.

Prices of scrap iron and steel have declined from 50 cents to 2.50 per ton during the past week at St. Louis. All dealers want to sell at once. Melters are taking advantage of this state of affairs.

HYDRAULIC NEVER TO REPLACE COAL

Interesting Figures Brought Out by Authority in United States Field

Dr. Charles P. Steinmetz, chief consulting engineer of the General Electric Company, New York, warns against a too general belief that the power of our water may ever completely replace the use of coal and oil for power purposes.

The maximum possible hydraulic energy of the nation, he estimates at the tremendous figure of 370,000,000 horsepower, which is little more than the total energy which we now produce from coal, and is about equal to the present total energy consumption of the country, including all forms of energy.

"This is rather startling," said Dr. Steinmetz. "It means that the idea that when coal once begins to fail we may use the water power of the country as the source of energy, is, and must, remain a dream, because if all our potential waterpowers were developed and every raindrop used, it would not supply our present energy demand.

"Thus hydraulic power may and should supplement that of coal, but can never entirely replace it as a source of energy. This probably is the strongest argument for efforts to increase the efficiency of our methods of burning coal.

"Obviously, of course, we can never hope to develop more than a part of the maximum potential energy of the water, and I merely cite these figures to show that our water power resources, if developed, to theoretical perfection, would still fall short of meeting the energy demands of the country to-day."

The total present developed water power in the United States exceeds 7,000,000 horsepower with 19,000,000 still undeveloped, and potential water power capable of development amounting to 31,000,000 horsepower.

The present use of water power saves the country from upward of 33,000,000 tons of coal annually.

BRANTFORD NEEDS MORE POWER NOW

But the Chances of Getting the Supply Seem to Be Very Limited

The shortage of coal, the scarcity of wood in the civic yards there were augmented when the Brantford city council was informed by the local Hydro-Electric Commission that this city was now carrying a load of 200 more horsepower than it was getting, and that the situation would get worse instead of better with the approach of winter, with lessened supply and greater demand. The only ray of hope was shed when the Gas Committee reported that with new fields opening up and available because of increased prices, the Dominion Natural Gas Company would be in a position to give assurance that a greater supply of better quality gas would be available for Brantford this winter.

Sell Forging Plant.—It is understood from a reliable source that the offer received by Canada Forgings for the Delaney plant at Buffalo will put the company in a strong position financially. A meeting of the shareholders has been called for Sept. 28th at the head office in Brockville to deal with the offer, which is said to be made by a syndicate. The operations of the company are stated to be running along smoothly and satisfactorily, and it was asserted by one of the directors that James Smart Manufacturing Co., one of the three component parts of the company, is alone earning enough to pay the common dividend.

Looking After a Big Family of Freight Cars

A Great Amount of System and Supervision Necessary to Avoid Endless Complications—How the C.P.R. Look After the Handling of Reports in the Car Record Office.

IN the early days of railroading, car records were not much in vogue for the reason that cars usually were confined to service on the rails of the owner. Shipments moving from one road to another were transferred at the junction point to cars of the receiving road. This condition obtained for many years, but with the expansion of industrial activities came through rates and through routes, and these aided by that all important factor—competition—gradually compelled all roads to permit their equipment to be loaded to points on other roads, with the understanding that the car and the contents would move through to destination without breaking bulk.

As cars commenced to move from one road to another, always subject to possible delays and diversions, it became necessary for car owners to keep a close tab on the movements of both home and foreign equipment. The same conditions made it necessary for the roads to get together and formulate rules and regulations to cover the interchange of equipment and to protect the accounting of car hire.

Prior to July 1, 1902, the mileage system of remuneration for the use of freight cars was in vogue, but on this date the Per Diem Rules became effective, and the latter are now in general use on all Canadian and American roads. Under the old system the owner of the car seldom received full return from the foreign roads for the use of the cars, but with Per Diem the road receiving a car must account for it to the car owner at the current per diem rate from the date of its receipt up to the date it is delivered to the owner or to another road, or in the case of a destroyed car, up to the date it is reported as a "destroyed" car to the owner, in accordance with the per diem rules.

Give all Information

Generally speaking, car records are maintained at all stations and contain everything there is to know in connection with the handling of the car contents, including the charges assessed or collected while in the terminal. Apart from the accounting features these records show the following information: Initials and number of car, kind of car, date and time of arrival, train reference, point of shipment and kind of commodity if a loaded car, date and time of notification to consignee of arrival of his shipment, date and time of placement, date and time of release, date and time car is forwarded, train reference, and, if car is loaded, kind of commodity and destination.

At stations where a great number of cars are handled there is also maintained a daily on-hand report, usually referred to as a yard check. This report shows the initials and number of the car, kind of car, on what track located and whether loaded or empty, and if held, for what purpose.

At stations where cars are interchanged with other roads, an interchange report is maintained which shows the initials and number of the car, kind of car. name of road to which car is delivered, date and time of interchange, name of billing station, name of destination station and kind of contents.

The movements of all cars on any part of the road and on foreign roads are re-

*Compiled by J. H. Rodgers, from Canadian Pacific Car Service office records, and the paper, "Car Records and Their Relation to Transportation and Car Accounting," read before the September meeting of the Canadian Railway Club, by J. D. Altimas, Asst. Gen. Supt. Car Service, C.P.R.

A GENERAL VIEW OF THE ACCOUNTING OFFICE. CAR SERVICE DEPARTMENT, C.P.R.

corded in the books of the Car Accountant, whose office is usually at headquarters. The basis of these records is the agents' interchange report, the conductors' freight or mixed train report and the foreign roads' junction report.

The interchange report now in use on all roads is authorized by the American Railroad Association and is known as the reciprocal form of report. The agent of the delivery road prepares the report in quadruplicate showing information for all cars delivered, and passes the completed report to the agent of the receiving road who checks the information shown thereon, and if he finds it correct, signs all four sheets, certifying to the receipt of the cars. He retains one copy of the report for his station record, sends one copy to his car accountant, and returns two copies to the agent of the delivering road. The latter keeps one copy for his station record and forwards one copy to his car accountant.

Under American Railroad Association rules where a railroad delivers a foreign car to a connection, not the owner of the car, he is obligated to advise the car owner the name of the road the car was delivered to and the date of the movement and to show whether the car was loaded or empty. This is called the junction report. Roads which use the cut up system preserve the interchange slips for foreign cars delivered and send them to the car owners as the junction report. This saves the delivering road considerable work and gives the car owner a first hand record, avoiding all errors due to transcribing.

The Interchange Report

Practically all of the larger roads now use the cut up or self transcribing system for conductors' train report and the agents' interchange report. Under this system the conductors' train report consists of one wide form giving all the information required, including an extra column for the date of the movement, also one narrow form, which is a duplicate of the wide form in so far as it refers to the initials and number of the car, number of station car is taken at and left at and date of movement. This narrow form has small holes punched in the margin between the lines to the left of the "initials" column for the use of the sorting clerks. These two forms are made at the one time by the use of carbon paper. In making entries on the narrow form it is not permitted to use ditto marks, as each slip, being separated from the rest, must show the complete information covering the car referred to.

The agents' interchange report consists of four wide forms giving all the information required, also two narrow forms which are duplicates of the wide forms in so far as they refer to the initials and numbers of the cars, name of road delivered by and name of road delivered to, name of station at which delivery is effected and date of delivery. The narrow forms have small holes between the lines to the left of the initials column for use of the sorting clerks. The narrow forms are of different colors—one pink for the use of the delivering road and one canary for the use of the receiving road. The pink indicates a delivered record, the canary a received record. The original and five copies of this report are made in one operation by the use of carbon paper. The information called for is shown on the section of the form, Fig. 2. For reasons before mentioned "ditto" marks must not be used on the narrow portion. These forms, when completed by the agents and conductors are forwarded promptly to the Car Accountant's office where they are entered into the car record books.

The handling of these reports in the car record office is a systematic and interesting operation. As soon as the mail is opened the reports are passed from the mail desk to the examining clerks who see that all information called for by the form is properly entered, after which the narrow forms are separated from the wide forms. The wide forms of the conductors' train reports

are immediately turned over to the Statistical Department for their use, while the wide forms of the interchange reports are filed for ready reference. The narrow forms are then sorted and arranged according to the number of the car entries on the form. The forms are then piled into packages having about 200 or 300 in each package, the forms showing the smallest number of car entries being placed on top. This is done to enable the cutter to dispose of the blank slips as they come from the machine and thus eliminate the unnecessary handling of blank slips by the sorting clerks. Interchange reports are given preferred handling.

Working by Weight

When the narrow forms reach the cutter they are put through the machine, and as the slips leave the machine the cutter separates the blank slips from the record slips, throwing the blanks aside, and placing the record slips into small boxes enclosed on three sides only, these boxes having their tare weight (equivalent number of record slips) stencilled on them so as to facilitate the weighing. These tare weights are checked occasionally to see that there is no variation. The cutting is accomplished by a machine of the advance lever type and when the reports are of uniform size with spacing and holes also uniform there is little chance for mutilation of the slips. The reports are printed on paper of uniform weight and when cut up weigh approximately 272 per ounce. They are weighed after cutting into slips and also at the close of the day, so that each sorting and entry clerk is credited with the correct number of slips worked. An ordinary druggist's scale is used and gives every satisfaction.

Sorting the Slips

The sorting table is usually a high desk, with its top surface on an incline, and fitted with two rows of spindles one inch apart, one row being about seven inches behind the other. The spindles are 4 3-4 inches high with a shoulder or collar about 3-4 of an inch from the bottom. The part below the collar fits into holes bored in the top of the desk. One or more spindles are alloted for each record and sufficient spindles to accommodate all records are looked after by one sorting clerk. The spindles are a little less in diameter than the holes in the slips so that the sorters can slip them on the spindles very rapidly. Lists are prepared which show what records are alloted to each spindle, and these are located in a suitable position on the sorting table. When sorting the slips are held in the right hand and sorted with the left, otherwise the car initials would be covered and the handling would be much slower. Sorting clerks generally handle about 26 to 30 slips per minute. The original sorting is done to suit individual requirements. Usually the first sorting is done in book form and the second in page order. The latter is not always economical.

The junction records when received on the standard junction report form are transcribed by typewriter to the cut-up form and are passed through the machine in the same manner as other forms and are then passed on to the sorters. Junction records received on the cut-up forms are at once turned over to the sorters for handling. At regular periods during the day the record clerks obtain the slips from the sorting desk and proceed to enter them in the books. By this method a record clerk does not have to handle any records except those that are to be entered in his book. The record books are of the loose leaf type and usually about 18 inches long by 17 inches wide. The home car record sheets are ruled about as follows: See Fig. 3.

One column about one inch wide for car number, then 31 columns 3-8 of an inch wide for the days of the month and one column about one inch wide at the extreme right for mileage as per diem purposes. Each page holds fifty cars and a book usually includes 5,000 cars in numerical order. The home car record usually is made up to take care of two months' records in order to avoid the necessary transferring of the records from one book to another.

The foreign car record sheets are ruled as follows: See Fig. 4. One column about 3-4 of an inch wide for the last account, another of the same width for initials, another for the car number, 1-4 inch columns for, kind of car, per diem days earned, checking, for each day of the month, and three or four 3-8 of an inch wide for mileage purposes. Each page holds fifty cars and each book has space for about 6,000 cars of which from 1,500 to 1,800 are actually in service at any one time. These books are made up to show cars in alphabetical road order and in numerical order and are indexed for ready reference.

Watching Interchanges

When a clerk is ready to enter records he first finds the space alloted to the car and then enters in the block which represents the date of the movement, the number of the station at which the car was taken and the number of the station at which the car was left. Usually the number of the station at which the car is taken already appears in the block and it is only necessary to enter the number of the station at which the car is left and a check mark drawn after the number of the station at which the car is left indicates that the record is complete. When a car moves empty the pencil line drawn above the number of the station at which the car is left shows the record is complete.

In the case of interchange records, a receipt from the connecting road is entered by showing the symbol representing the road in the upper left hand cor-

THE PICTURE TO THE LEFT SHOWING THE FOUR SORTING CLERKS, ILLUSTRATES THE FIRST SORTING AFTER THE FORMS ARE CUT INTO SLIPS. TO THE RIGHT—SORTING THE SLIPS INTO PAGE ORDER.

ner of the book immediately followed by the number of the station. To indicate a delivery to a connecting road the symbol of the road is entered in the lower right hand corner of the block preceded by the station number. In practically all cases the number of the station appears in the record and it is only necessary to enter the symbol. Home record clerks average about 300 entries per hour, whereas foreign record clerks average about 225 entries per hour.

Roads which do not use the cut-up form of reports simply take the interchange reports, conductors' train reports and the junction reports from the mail desk, place them in suitable packages for handling and pass them around to the several record clerks who enter the movements direct from the reports to the books. Under this method each clerk must examine every car shown in the report in order to pick out the records which are to be entered in his book. This takes considerable time and labor.

With a record of every movement made by cars on his own rails, with the interchange record of cars delivered to and received from connections and with the junction record of his cars furnished by foreign roads, a car owner has a complete record of every one of his cars during each month of each year. This enables him to keep a close check on the handling of his cars by foreign roads and to check the earnings of his cars under any and all circumstances. He is also in a position to know what other owners' cars are doing on his rails.

Car records properly maintained and kept up-to-date are of great benefit and serve many purposes of the Transportation Department in addition to being the basis of the accounting for car hire. The following are some of the uses to which car records are constantly put:—

To furnish records to the public in connection with shipments in which they are interested.

To furnish records to the Transportation Department to assist in tracing freight urgently required at destination or which may have been unduly delayed in transit or which may be required to be diverted in transit.

To furnish location of special class equipment, such as refrigerator, tank, potato, Eastman heaters, palace horse, special grain cars, etc., to enable the Car Service Department to keep them in the special service to which they are allotted, or to move them to points where they are required, also to see that such cars are used to full advantage.

To furnish car movements, loaded and empty, to the Transportation Department to assist in tracing delays and placing responsibility and to the Claims Department to assist in locating overs and shorts and disposing of claims.

To check the handling of cars on foreign roads and thus overcome unnecessary delays and diversions.

To furnish weekly or monthly statements of the distribution of all classes of equipment by districts or divisions.

To furnish records of car loads transhipped in transit.

To furnish mileage, loaded and empty, made by special class cars or cars of any class.

To check the record of foreign equipment to see they are not unduly delayed or used contrary to Car Service Rules.

To check repair bills as to location.

A record clerk works on the average about six hours a day in entering records and about two hours a day in furnishing locations, movements and other information.

The car record is the basis of the car hire accounting system and the car records of foreign equipment handled are usually turned over to the Accounting Department about the tenth day following the close of the month. The first duty of the clerks on accounts is to ascertain what records are incomplete, i. e., what cars are short on interchange receipt or delivery and to check back against the interchange reports to see if such records were skipped by the record clerks. The second operation is to extend the number of days each car was on the rails, and where there is an incomplete record, to list the initials and the numbers of the cars so as to aid the correction staff in completing the records.

Where a missing delivery is involved per diem is usually allowed up to the date the car is last reported moving. In the case of a missing receipt per diem is allowed from the date car first moved. When the record has been completed, the balance of the per diem, if any due, is allowed in a subsequent month's report.

After the per diem days have been extended, a per diem report is prepared for each road, showing the car number and the number of days earned and same is forwarded to the car owner, within forty days from the last day of the month in which the per diem was earned. On the receipt of the per diem report by the car owner he enters in the record opposite each car the number of days per diem allowed by each road, and after all the per diem reports have been carried, if his records indicate a shortage, he has the privilege of making claim against the road which, according to his records, has short-paid the per diem. Such claims to be valid must be handled in accordance with the rules.

In addition to preparing reports for per diem earned currently, reports are also prepared to cover errors and omissions in per diem reports of previous months, to cover switching reclaims, to cover rule 14 reclaims, namely, cars held by one road on account of inability

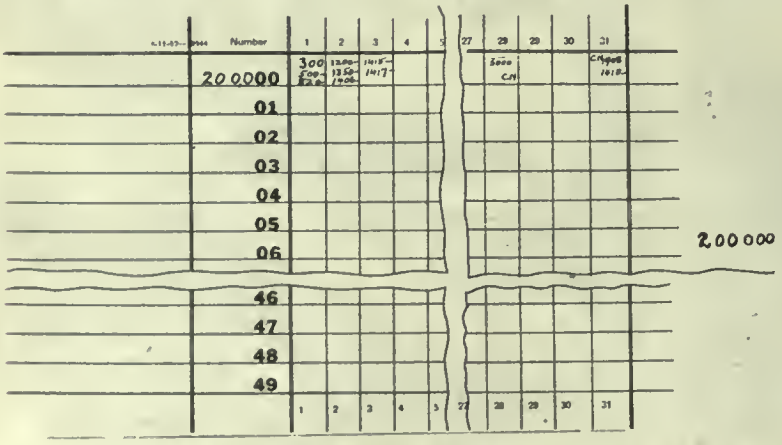

FIG. 3—HOME CAR RECORD SHEET. SPACE ON EITHER PAGE, OR SIDE OF THE SHEET, FOR TEN MONTHS' MOVEMENT OF ANY OR ALL CARS IN THE SERIES.

of another road to receive and to cover reclaims due to special conditions.

Under Per Diem Rules, per diem must be paid by a road using a car to the owner for each and every day car is in service on that road, but where a road handles a car in terminal switching service for another road it is entitled to an arbitrary reclaim from the carrier road of an agreed number of days not to exceed five for each car handled in such service. Per Diem Rule, 15 also provides that where a road holds cars on account of another road to receive them, the holding road is entitled to reclaim from the road on whose account the cars were held the full amount of per diem involved, always provided that due notice is given in accordance with the rules.

The Per Diem Rule Agreement, to which practically all American and Canadian roads subscribe, is promulgated by the American Railroad Association and lays down rules to govern every phase of per diem accounting. These rules in their original form were adopted and made effective on July 1, 1902. Since that date there have been changes from time to time in the rate to take care of the increased cost of owning and operating a car. At the present time the rate is 90 cents per day. The main objection to the rules in their original form was that no penalty was provided for the non-payment of per diem earned

and as a result the car owner was put to considerable expense to collect what rightly belonged to him. On July 1, 1913, a penalty of 5 cents per car per day was made effective when per diem was not paid to the car owner within six months from the last day of the month in which the per diem was earned.

than anything else to force the railroads to keep proper car records. While it may be true that the cost of accounting for car hire under per diem rules is much greater than under the mileage plan, there is little question that the extra saving more than balances the additional cost. Under the per diem car system a car owner knows exactly what his cars earn and methods are provided for accurate accounting, whereas, under the mileage plan the car owner had no means whatever of checking the earnings of his equipment on foreign roads and had virtually to accept whatever was allowed. In the old mileage days many cases of deliberate dishonesty in accounting were developed and the conditions helped a great deal in the agitation that was carried on in favor of the adoption of the per diem system.

Car records to be of value must be properly maintained and kept up-to-date. This can only be accomplished by the hearty co-operation of all concerned in the preparation and handling of the reports and the records. In the Car Accountant's office surprise checks are used to a great extent and with good results to ascertain if the correct and complete information is being recorded in the books. With this system the clerks soon realize that they must do their work properly or make way for others who will. The secret of the whole transaction is system and supervision.

Nine Examples of Jig and Fixture Practice

Various Principles Are Discussed Such as the Snapper, Universal Chuck, Turnover and Slide Stop Motion. Each Jig Depicted Has Proved to Be the Best for Its Own Particular Work.

By J. H. MOORE

TAKING it for granted that everyone realizes the advantages of efficient jigs and fixtures, we will proceed to describe seven interesting examples of fixtures which have proved real producers for The International Harvester Co., Hamilton, Canada.

The first of these depicted at Fig. 1 is what is known as a snapper jig. It is so-called because it snaps into place quickly and holds the work very firmly. Referring to the illustration we see that A is a solid cast iron base, while B shows one of three jaws very similar to those used on an ordinary lathe chuck. These jaws are adjustable and come in at the same rate of speed towards the centre, receiving their motion from the action of handle shown to right of the letter A. They, of course, slide in the Tee shaped slides C. This feature means that the work E, which is a portion of a manure spreader, is always centred before the top portion of jig comes down on it.

Having centred the work, the handle F is released which brings down the cup shaped brush D on top of the boss on the work E. The pin H acts as a guide, and underneath this pin at each side of jig is fastened a strong spring. The action is apparent. The spring pulls the top down with considerable pressure, the lever G being part of the movement. This type of jig is widely used at the plant we speak of and can handle a large variety and range of work. The operation in this particular case is the drilling of a 1 1-4-in. hole through the centre of the work E. The casting as shown is approximately 16-in. diameter, but the jaws of jig can come in to take a much smaller piece if necessary.

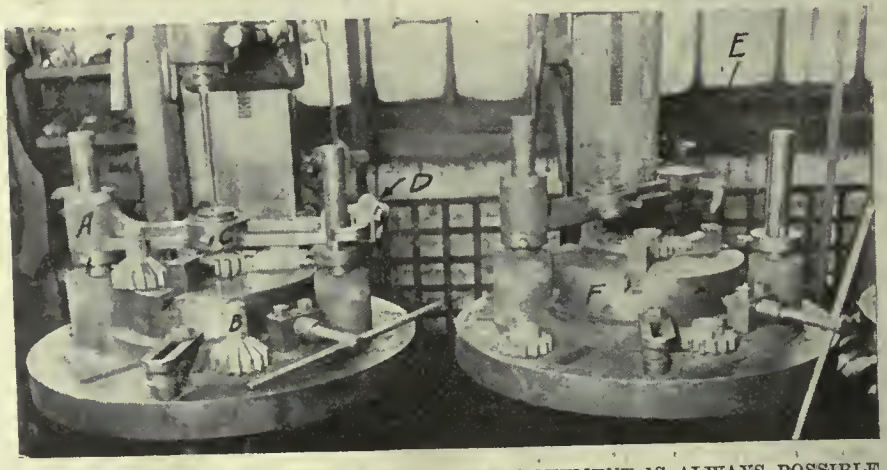

FIG. 2—THIS STYLE OF JIG PROVES THAT IMPROVEMENT IS ALWAYS POSSIBLE.

An Improved Type

The jig as described at Fig. 1 was the original snapper type, and hundreds of the same have been made with splendid success. There is a saying that no matter how good a thing is, it can always be improved upon, and this holds good in the present case as Fig. 2 will illustrate.

The fixtures shown in this view are really improved offshoots of the snapper jig, but are termed the universal chuck type, owing to their having an ordinary universal chuck as the holding unit.

It will be noted that a universal chuck is placed directly in the centre of the jig base, and that two bosses are placed on each side of the aforementioned base. In these bosses are fastened two guide pins. The swinging member A has a cup shaped bush in the centre boss C. The quick action clamp D grips the other guide rod, and by referring to E you can see the clamp released. In action you loosen a purled knot a quarter turn which brings the clamp to the position shown at E allowing you to swing the top members of jig out of the way. B illustrates the work in one case, and the other view shows a still different type of gear being drilled.

The great advantage of this type of jig over the one depicted at Fig. 1 is the fact that by changing the bushings at C to suit the nature of the work, you can use the fixture for an almost endless variety. Of course it is only adapted to parts of round shape, parts which can be gripped in the chuck. Since installing the improved design, the former shown at Fig. 1 have taken a back seat, although for certain classes of work they are still ideal.

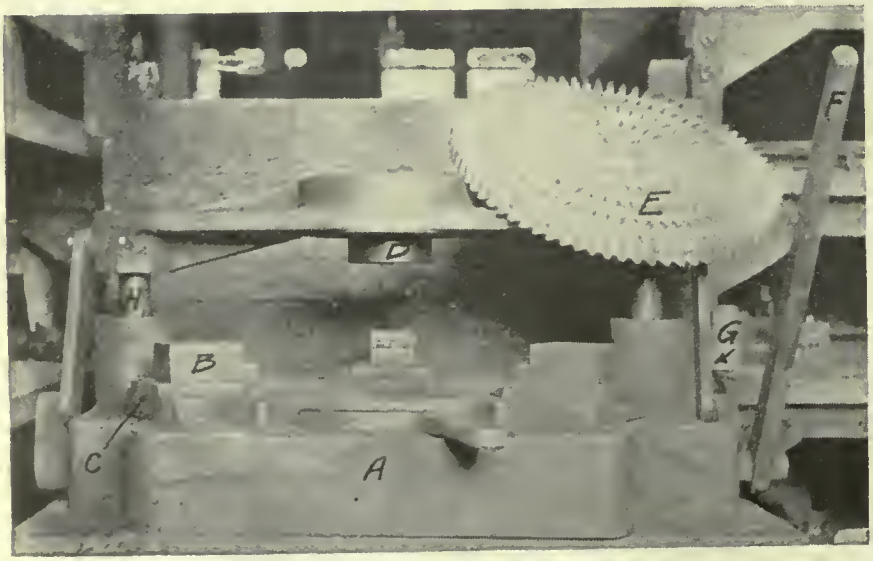

FIG. 1—THIS STYLE JIG IS KNOWN AS A SNAPPER JIG.

Reaming Jigs

The next two examples are shown at Fig. 3. Both jigs are used on the same piece, and we will take them up in order starting with the one shown to the left. The work being performed is that of reaming from the cored hole a 2 3-8-in. hole. Note the action of the clamp A. On inserting the piece in the jig, the shaper wedge B is driven in, this in turn raising the back end of clamp A, and pressing the point of the same down firmly on to the work. The swivel screw C is next brought into action, this guaranteeing that the work goes up into correct position.

To the right is shown the reaming of

FIG. 3—TWO EXAMPLES OF REAMING JIGS. NOTE THE METHODS OF HOLDING.

the second hole, 1 5-8 in. diameter. The work is gauged from the former hole reamed by means of the pin D, and is held in position by both the small screw shown at top of jig, and the taper wedge E. The view at F. illustrates clearly the details of the piece for which these jigs were made.

Turnover Jigs

Fig. 4 illustrates two other jigs known by the term turnover jigs. The fixture to the left is used to drill two holes in the piece A at the points shown by cross marks in chalk. The method of obtaining these two positions is very simple. Note the slot C at lower portion of the fixture. It is cut at the correct radius, and of sufficient length to allow the correct distance of travel. Two bushings, which are hidden from view by the work in the jig, guide the drills to their proper positions. In action the operator merely places the work on the circular shaped portion of jig, fastens it by the taper key B, drills one hole at one extremity of the slot, and one at the other. The pin which is inserted in the slot acts as a positive stop. This type fixture is easily made and is very efficient.

The second jig, that to the right, is used to drill the tongue for a whiffletree shown at D. Note the two chalk cross marks. This denotes where the holes are drilled. There are four holes drilled, two on either side of the casting.

The method of procedure is as follows: The work is placed in position and held by the taper key shown. The two holes are drilled on one side of the casting, then the moveable portion of the jig is pulled out of a slot in the stationary member, and revolved 180 degrees, then pushed back into locking position once more. The collar F prevents the moveable portion being pulled out too far. The remaining two holes are now drilled, and of course they cannot be anything else than opposite the other two, owing to the safe method of locating.

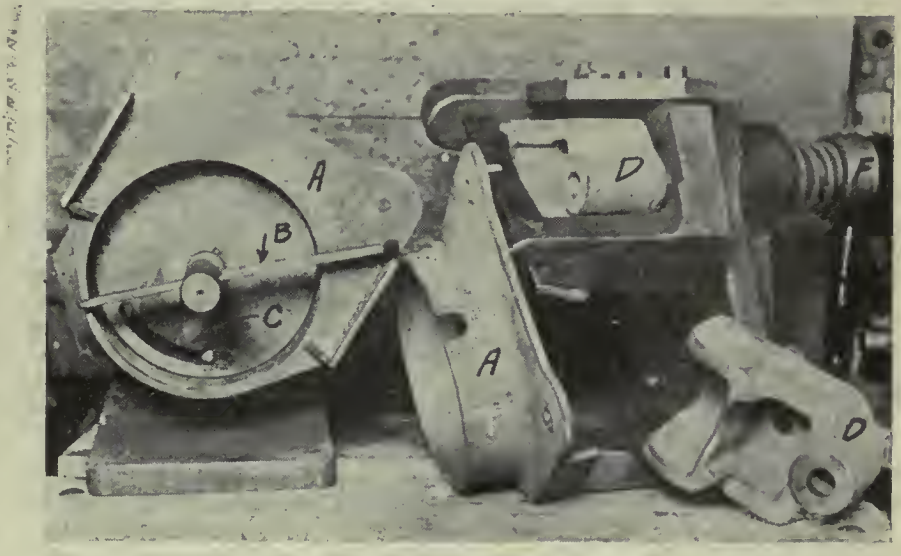

FIG. 4—TWO JIGS THAT EMPLOY THE TURNOVER PRINCIPLE

This turnover principle is used to great advantage in the plant we speak of, hundreds of various style turnover fixtures being used.

Three Varied Jigs

The last photo, Fig. 5, illustrates three distinct types of jigs. Starting from the left we find as follows: The fixture to the left is used to drill the two top holes on the part A which is a portion of a fertilizer. These holes are on a radius, and here is how they are drilled. The work is placed on the moveable portion B, over the centre rod, then fastened in position by means of the taper key shown. This portion B slides on a guide slot about 4-ins wide, and of the correct radius to accommodate the holes. Two bushings are placed in correct position at top of piece B. First one hole is drilled at extremity of slot partially shown in stationary member, then the other is drilled at opposite position. To allow for adjustment, an adjustable screw with lock nut is placed at either end of the radius shaped slot, and any adjustment necessary can be accomplished very easily.

The jig shown at the centre is simply a pin jig to drill the pin D as shown, but the ejector used is worthy of note. The work is placed in Vee block E and drilled through a bushing in the regular manner. On being completed, the operator merely touches with the palm of his hand the collar at end of F and the spring accomplishes the rest. It shoots the pin out of the jig, and of course springs back into gauging position as soon as the hand leaves the collar F. The output on this particular piece has greatly increased since installing this style of ejector

The last fixture to be discussed is used to drill the four holes in piece G. Four bushings H are placed in correct location and work fits into jig up against stop pin shown, and held in position by screw with handle.

This portion of the jig moves in a radius similar to fixture shown on the left, but in a horizontal position. A radius shaped slot in the base of jig limits the travel.

From the foregoing examples of jig practice readers will no doubt get ideas for the adoption of similar principles to their work, for after all it is the fundamental principle underlying the making of any jig that really counts.

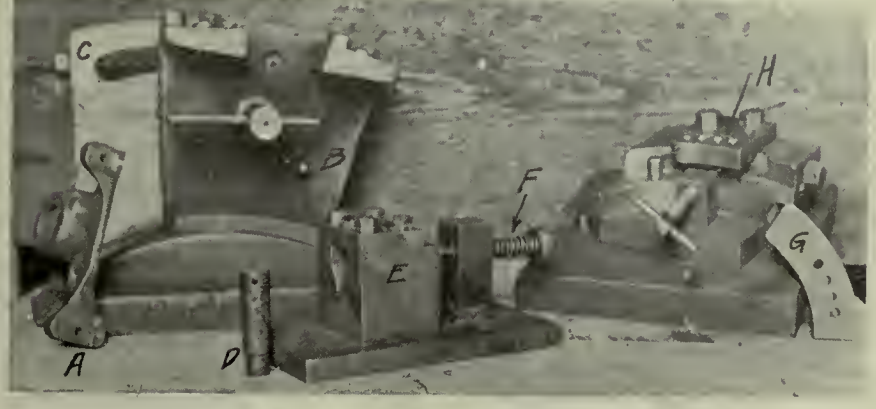

FIG. 5—THREE JIGS, EACH WITH ITS OWN PRINCIPLE.

The Heat Treatment of Locomotive Forgings

The Article Deals Not Only With Locomotive Forgings, But Similar Parts as Well—The Author Presented This Matter Before the Buffalo Chapter of American Society for Steel Treating.

By LAWFORD H. FRY

THIS paper presents some notes on the theory and practice of the heat-treatment of steel forgings with particular attention to larger forgings such as locomotive driving axles and similar parts. In dealing with the theory my idea is to give only a general outline of the metallurgical theories of hardening and to compare these theories with what we see every day in practical work in the treating plant.

The term "heat treatment" is a somewhat loose one. It may properly be used to describe many processes, and some critics assert that it has been used to cover a multitude of sins. In the present paper the term is used to cover quenching from a temperature above the critical range, followed by a drawing at a temperature below the critical range.

Theory of Heat Treatment

The practice of heat treatment as defined above is based on the fact that the quench produces great hardness and brittleness, while the draw reduces the hardness and restores ductility, in proportion to the temperature reached.

It is not too much to say that our present civilization—based as it is on engineering—is dependent on the simple fact that steel hardens on being quenched. In spite, however, of the great importance of the process, and of the amount of research work that has been done on it, there is still room for doubt as to the exact nature of the reactions which produce hardening, and some of the most eminent metallurgists hold divergent opinions on the subject.

We know well enough how the physical properties of the steel are affected by quenching and the microscope has carefully followed and recorded the visible changes in the interior structure of the steel. It is true, however, that the scientific explanation of the hardness produced by quenching still remains no more than a theory, and as yet the most eminent metallurgists are not unanimous in their choice of a theory. The changes in structure as revealed by the microscope can be summed up in a few words. As it comes from the forge the steel has a coarse irregular structure with comparatively large grains of pearlite inclosed in a network of ferrite. On being heated up through the critical range the carbon, to which the pearlite structure is due, dissolves in the surrounding iron so that at temperatures above the critical points the steel becomes a uniform homogeneous solid solution of carbon in iron. By rapid quenching this structure can be preserved into the cold state, and the resulting steel will be extremely hard. If slow cooling is allowed, the carbon comes out of solution as the critical range is passed, pearlite and ferrite re-form and the steel reverts to its former condition except that the grain is refined. The steel is then as soft as or softer than before. An intermediate rate of cooling produces an intermediate structure and an intermediate hardness.

Theories of Hardening

To explain these possible changes in hardness many theories have been offered. Those backed by the best known metallurgists may be collected into three groups and designated:

(1) Allotropic iron theory.
(2) Carbonist theory.
(3) Strain hardening theory.

Osmond in developing his theory of the first group assumed that iron occurred in three forms, or allotropic states, through which it passed with a change in temperature. He concluded that the change from one form to another required time, so that a rapid cooling prevented the iron being transformed to its usual low temperature form, and trapped some of the intermediate form which was hard and brittle at ordinary temperatures.

Arnold attributes hardening to a direct action of the carbon in the steel. He supposes the existence of a carbide of iron called hardanite, which is very hard, and which by being retained on quenching imparts hardness to the steel. It has even been suggested by other exponents of the carbon hardening theory that the sudden compression of the metal on quenching transforms the carbon into minute diamonds which produce the hardness.

In the more modern theories, hardening is held to be produced by the strains set up on quenching. We are all familiar with the fact that if a piece of steel be strained beyond its elastic limit it will be hardened. This has been explained by Beilby by his theory of amorphous vitreous cement. He showed that when the surface of a metal is polished, the pressure used transforms the outer layer from a crystalline structure into a glassy amorphous film which is very much harder than the crystalline material. Recent experiments with balls for ball bearings have shown that the polished skin on the balls adds 30 per cent. to their strength. This hard amorphous material accounts for the increase in strength and hardness produced by cold working. When a piece of steel is stretched or compressed beyond its elastic limit the crystals throughout the metal slip over each other, at each slippage surface a film of hard amorphous vitreous material is produced. The films are too thin to be visible even under the microscope, but are numerous enough to harden the metal throughout. Beilby further noted that the amorphous material reverted to the crystalline condition on being heated. As Carpenter has pointed out the change from the crystalline to the amorphous condition can be effected by work but not by heat, while the change in the reverse direction from amorphous to crystalline can be produced by heat only and not by work.

Beilby's theory having been found to fit all the conditions of cold hardening, was proposed in 1914 by three different groups of scientists as an explanation of the phenomena of hardening by quenching. The form in which the theory was proposed by Edwards and Carpenter appeals to the writer as giving the simplest explanation of the observed facts. An account of this theory is given in the paper on the Hardening of Steel by Carpenter, read before the Royal Institution, March 7, 1919, and reprinted in Engineering, March 21, 1919. It is pointed out there that during the quenching of the steel severe internal strains are set up—

(1) By the shrinking of the outer skin;.

(2) By the suppression of the critical change.

These strains develop intercrystalline films of hard amorphous material just as do the strains produced in cold working. The heat in the steel would tend to recrystallize the films, but if the quenching is sufficiently rapid the temperature at which the films are stable is reached before they have time to revert and the metal is hardened. The greater hardness with high carbon is accounted for by the greater strains set up in the suppression of the critical change.

To the practical steel treater it is interesting to have the hardness at which he is aiming thus linked up with the quenching strains which are the source of the difficulties and dangers of the process. If the strain hardening theory is accepted, the process of heat treatment is seen as the art of producing and controlling strains. The first step in the study of the practical application of heat treatment is an examination of the strains produced by quenching.

As mentioned above, Carpenter point-

*Standard Steel Works Co., Burnham, Pa.

ed out that the strains producing hardening might be produced in two ways:

(1) By the shrinking of the outer skin.

(2) By the suppression of the critical change.

I do not know that any attempt has been made to separate the effect of the two classes of strains, or to compare the part played by each. A general consideration of the matter leads to the belief that the strains from skin shrinkage are of secondary importance in producing hardness, but have a primary part in producing troubles. It is to be noted that the strains from skin shrinkage distribute themselves unequally through the pieces, being greatest at the surface and decreasing toward the center. The strains from suppression of the critical change on the other hand have their origin in the interior of each grain and can, therefore, be uniformly distributed throughout the piece. Further these intragrain strains can be produced without distortion of the piece as a whole. It follows, therefore, that the ideal condition in quenching would be reached if it were possible to produce the critical change strains without the skin shrinking strains. Unfortunately this is, from the nature of things, impossible. When the piece is plunged into the bath the skin is chilled first. The skin contracts and is thus put into tension while the interior is in compression. The more rapid the cooling of the skin the greater are the stresses set up, and in the case of a large cylindrical forging such as a locomotive driving axle it is possible by too rapid a quench to split the piece longitudinally. As the piece cools a second danger develops. The outer skin cools and contracts while the core remains hot and expended. To accommodate itself to the core without cracking the skin must stretch. In this stretched condition it becomes rigid, while the core still has a considerable amount of contraction to carry out. Hence in the final stage of cooling the core is pulling away from the skin and if this final cooling is too rapid the core may be ruptured.

Let us now examine the action of the quenching medium on the hot steel. Each particle that is effective in quenching comes in contact with the hot piece, moves along its surface taking up heat for a time, and then is swept away by the convection or other currents in the medium. The amount of heat taken from the piece in a given time will depend on the number of particles brought into contact in that time and on the amount of heat each particle can take up. Hence a light oil quenches quicker than a heavy oil because being more fluid the convection currents bring more particles per minute into contact. Water quenches more rapidly than light oil both because it is more fluid and because each particle can take up more heat. It also follows that a given medium will quench more rapidly if the convection currents are supplemented by a forced circulation. This is illustrated by the figures given below. They are obtained from two similar locomotive axles made from the same steel, quenched from the same temperature in the same medium, a solution of one part cutting compound to three parts water and drawn at the same temperature. For axle A the quenching medium was circulated only by its natural convection, while for axle B vigorous circulation of the medium was obtained by stirring with an air jet. The time of cooling through the interval 1450 degs. F. to 700 degs. F. was decreased from 16 to 9 minutes by this stirring. The physical results were:

Axle	Circulation	Time to Cool from 1450° F. to 700° F. Min.	Elastic Limit Lb. Sq. In.	Tensile Strength Lb. Sq. In.	Elon. in 2" Per Cent.	Red. of Area Per Cent.
A	Natural	16	49,500	95,000	20.5	43.0
B	Forced	9	69,000	105,000	21.0	42.0

Comparative figures for the quenching speed of different media are given in Table I. These are obtained from experiments made with locomotive axles, and while they are perhaps not universally applicable, they serve as a basis for illustrating the difference in cooling rates, and the differences in stresses set up by quenching in the different media. To see the effect on the stresses produced consider a section of the piece quenched having the face A A A A in contact with the medium, while the face B B B B is towards the hot interior of the piece. The cooled face A will contract while the face B is kept hot and expanded. This strains the material. The strain which we can measure most conveniently by the stress it sets up will depend on the difference in temperature between the faces A and B, or, more strictly speaking, on the temperature gradient between the two faces. The faster the heat is taken away from the face A the greater the temperature gradient and the greater the stress. The tables show the calculated figures for temperature gradient and stress for the various rates of cooling.

The effect of the size of the piece must now be considered. The time required to cool a piece of steel through the critical range depends on the rate at which heat is taken out per unit of surface and also on the amount of metal back of each unit of surface from which heat has to be extracted. For example, a bar 1 inch in diameter has 0.25 cu. in. of metal for each square inch of surface, while a 10 inch. bar has 2.5 cu. in. of metal per square inch of surface, that is, 10 times as much metal to be cooled through each square inch of cooling area. Therefore, cooled in the same medium the 10 inch bar would take something like ten times as long to cool through the critical range as would the 1 in. bar. This effect of size is clearly shown in the difference in physical properties between large and small parts when both are given the same treatment. Table 2 gives the results of an experiment to illustrate this point. From two locomotive axles test pieces were cut with a hollow drill before treatment. These pieces about 1¼ in. in diameter by 5 in. long were put back into the hole from which they were cut and the axles heated for quenching. Just before quenching the pieces were taken out of their holes and quenched independently of the axles, but at the same time and in the same medium. They were then put back into place and the axles drawn back. The physical properties of the test pieces and axles are shown in the table. It will be seen that the test pieces are considerably harder than the axles. As a further example of the effect of size Tables 3 and 4 have been compiled showing the physical properties of large and small axles quenched in oil and of small test pieces quenched respectively in air, oil and water.

The property most affected is the elastic limit which is about 50,000 pounds per square inch for the 12 in. locomotive axles and 57,000 to 59,000 pounds per square inch for the five and six inch trolley axles. Test piece No. 6, which was 1½ in. in diamter, quenched in the same oil as the axles, gave 93,500 pounds per square inch elastic limit. The steel in all cases is a carbon steel with about 0.50 per cent. carbon.

Column 4 gives the approximate time taken to cool from 1450 deg. F. to 850 deg. F. The elastic limit (hardness) in-

creases steadily as the time of cooling is reduced. Test piece No. 5, which was cooled in air, cooled more rapidly than the quenched axles and is consequently harder. Micro-photographs of the three test pieces quenched respectively in air, oil and water show a fineness of grain in proportion to the rapidity of cooling, but this is an accompaniment of the hardness and not its cause.

Coming now to the application of the principles we have considered, let me present some notes on the practice of the works with which I am connected. Before the war our heat treating experiences covered locomotive forgings.

With the entrance of this country into the war we were requested by the Government with all the force of a command to undertake the manufacture of nickel steel forgings for the 155 m/m guns and howitzers. Of these forgings the largest piece is the gun tube which is about 20 feet long with a bore 5½ in. at the breach and 9½ at the muzzle, the weight being about 3,900 pounds.

Under the advice of the Ordnance Department, we put in vertical oil fired furnaces and experience led us to choose water as a quenching medium.

In gun manufacture the tests are taken two from each end of each forging transversely, that is to say, the axis of the test piece is taken across the direction of forgings. As a consequence, if the steel is fibrous, the fibre runs across the test specimen and the latter fails to give proper elongation. This trouble cannot be eliminated by heat-treatment, as it is inherent in the steel. I think it is safe to say that with a properly operated treating plant, at least ninety per cent. of the trouble encountered has its source not in the treating plant, but in the open hearth where the steel is made.

In the gun treatment the greatest chance of purely treatment trouble lies in the time of immersion in the water. It has been pointed out that if the final cooling of a quenched piece is carried out too rapidly quenching cracks may be produced. The nickel steel gun forgings with their varying sections proved to be very susceptible to this trouble. Finally we developed the practice of varying the quenching time to suit the varying sections of the piece. For example the gun tube would be completely immersed and quenched for two minutes, then the thinner muzzle section withdrawn and the heavier breech section given another minute in the water. As a rough approximate figure it was found proper to give an immersion of one minute for each inch thickness of wall in the forging.

In returning to a peace basis of manufacture, the equipment and experience obtained in gun making is available for the manufacture of locomotive forgings. The first question that arises concerns the relative merit of oil quenching as formerly practiced and of water quenching as used for guns. In giving preference to water we follow the lead of the Pennsylvania Railroad, who have been pioneers in the introduction of heat-treated locomotive parts. Of the two media, water by reason of its drastic quenching power takes first place in the production of desired physical properties in the steel. Any argument in favor of oil is based on the danger of quenching cracks if water is used. The answer to this is to have a carefully organized shop and to watch closely the time that the material is left in the water.

In conclusion I sum up the requirements in successful heat treatment as follows:

1. Select sound, well-made steel.
2. Heat uniformly to the proper quenching temperature.
3. Quench rapidly but withdraw from the bath at a sufficiently high temperature.
4. Draw uniformly and accurately.
5. Submit to a shock proof test before putting into service.

By correct practice along these lines the steel will give from 40 to 60 per cent. better service than the same steel untreated.

(Acknowledgment to Mr. H. P. Tiemann is due for assistance obtained from his book, "Iron & Steel.")

TRAINING THE WORKERS

The General Electric Co. has established in connection with its educational system a business training course for college graduates without technical education.

According to the company, this course is aimed to give training in the principles of higher accounting, a knowledge of which is of great importance to those who hope to become executives; to explain the essential elements of business law made necessary by Governmental supervision of corporations, the tax laws, and other complexities of our modern economic life; and lastly, to apply this general knowledge concretely to the business of the company, which is necessarily intricate owing to the size of the organization, the volume of its sales and the wide range of articles manufactured.

The training course consists of actual employment during the business day, in one of the departments where the student will become familiar with the practical work and the departmental functions. The class work will engage the best efforts of the student for eight or ten hours each week outside the class periods, which are held two evenings a week from 5.30 to 7.30 p.m. The course is divided into semesters and is in progress during the usual months of the college year.

In a paper entitled: "Some Aspects of Electrolysis of Pipes," presented to the American Waterworks' Association, Professor G. Alleman points out that damage only occurs where the leakage current either enters or leaves the pipe. It can be easily calculated that one ampere flowing continuously from an iron pipe for a period of one year is equivalent to 20 pounds of iron or 74 pounds of lead, and it must be remembered the current which leaves the pipe at one point may return at another place if the electrical conditions are favorable. In consequence, and as supported by experience, the effect of the current may correspond to any multiple of these two equivalents. Iron pipes are not corroded when electrically negative, and the opposite condition applies to lead pipes, but it is also possible under certain conditions for lead pipes to be corroded when electrically negative.

The British American Shipbuilding Co. has closed its doors and the activities of one of Welland's foremost industries are ended. The loss of this splendid industry is a serious one, and hopes are entertained that the plant, which is for sale, will be purchased.

A Real Home for Out-of-Town Apprentices

Realizing That Many of Their Apprentices May Be Out of Town Boys, This Concern Has Set Aside a Special Home for Their Use—Read the Particulars, It is Well Worth While.

By J. M. HARRISON

NO doubt many an old timer will remember the period when machinist apprentices worked for the handsome sum of 75 cents weekly. The writer himself did not come under such a classification, but received the small fortune of $3 for his initial year at the business. Contrast the two former conditions with those of the present day. An apprentice receives a better salary, works under better conditions, and in every respect has a real chance to advance. In some plants, including the one we will mention later, apprentice classes are formed, and in these classes are taught the different branches of mathematics. Some concerns hold these lessons right in their plant, while others send the boys to some nearby technical school, but in either case the principle is the same.

The chief aim is to advance the apprentice as speedily as possible, allowing him to obtain both the practical and technical knowledge. In the old days if an apprentice made up his mind to reach more than the usual standard, it meant burning the midnight oil, and plunging into whatever textbooks he could find on the subject. These unfortunately were sometimes not of the highest order.

The young chap learning his trade at the present time has very little excuse to offer if he does not advance in his profession, for even should his concern not hold apprentice classes as already described, there is always the modern technical school evening classes which are open at a very low cost. Competent instructors are there to see that the boys following up their various professions get a thorough technical training, and it depends on the interest taken by the student what the final result will be. be.

The well-known firm of Brown and Sharpe Manufacturing Co., Providence, R.I., have always been noted for what they have done for their apprentices, but they have added still another feature of interest, namely, a home for out of town apprentices.

Realizing that many of their apprentices may be out of town boys who are taking the training in their apprentice department, they have set aside the home as shown in the photograph for such lads. It is located in a good residential section of the city, and is only a short distance from the works.

On the ground floor are the housekeeper's apartments, two sleeping rooms, a living room and a closed in sun porch. On the upper floors are good sized halls, sleeping rooms, toilets and a large wash room containing lavatories and shower baths. Hot water is always available from an automatic heating system, and there is steam heat in every room.

Each boy has an extra width spring cot with mattress, pillows and bedding of the best quality, a chiffonier, an armed rocker and rug, and each room contains a study table and chair. There is no gas in the boys' apartments, all lighting being by electricity. Bath and hand towels are furnished and these, together with the bedding, are laundered by their own electrical equipment in the basement of the house.

The living room is furnished with an aim toward comfort and homelike environment, and a cabinet Victrola adds to the enjoyment of the evening and week-end hours of the boys. A supply of magazines is always on hand and through the extension service of the Providence Public Library the book shelves are kept filled with good, wholesome reading matter. The closed in sun porch, opening through French windows from the living room, makes an attractive place for lounging and games.

The house is under the supervision of the apprentice department, but is directly conducted by a responsible housekeeper and an assistant. There are no set rules, the boys simply being asked on coming into the house to do there as they would in their own homes. The policy is to maintain a thoroughly homelike atmosphere and to avoid the institutional tendencies often evident in such places.

No meals are served, but there are boarding places nearby where board may be obtained at the current rate. Room rent is not taken out of the pay, but each boy pays the housekeeper a fair amount weekly, this charge including the towel service.

Application for a room is made with the application for an apprenticeship by sending a note with the application or by writing on the margin of the appli-

APPRENTICE HOME OF BROWN & SHARPE—EXTERIOR AND LIVING ROOM.

cation blank. If there are no openings when the apprentice begins his course his name is placed on the waiting list and he is helped in finding a satisfactory room to use until there is a vacancy in the dormitory. Some of these temporary rooms are with families of men long employed by the company.

Our boys like to live at "Apprentice House." It is clean and quiet, and affords opportunities for good companionship that may well be compared with the valuable associations of a college fraternity house.

A scheme such as this is to be highly commended, and it goes to show how much this concern has the interest of their apprentices at heart. No wonder the boys like to live at such a house, for under such careful management it is always kept clean and quiet, and affords opportunities for good companionship which may well be compared with the system adopted by various colleges.

HANDY INFORMATION

In the September copy of "Threads" there is some information which is well worth reprinting. The matter we refer to is used in the "He wants to know" section, and here are the questions asked, and the answers given.

The first deals with information on the tolerance of diameters of screws before threading, the answer being as follows:

The best practice is to have the stock turned to correct diameter before running the thread chasers on. When the stock is much oversize, it puts the die head in a very bad position, acting both as a milling tool and a threading tool. This one point causes as much screw threading trouble and breakage of chaser teeth as any other one cause.

A customer has been successful in threading ⅜-inch—16 malleable iron lugs with a geometric threading machine, where the thread was cut directly on the casting, the pieces being 1-32-inch oversize, rough, and the threading operation reduced the diameter to about 1-64-inch under size, because the pieces were galvanized after threading. The chasers threaded 1,000 pieces between grinds. This customer referred to their work as "a strenuous job."

The next question was this "Are high speed steel chasers preferable to carbon?"

High speed steel chasers are used when speed is the chief consideration. They are not recommended where an especially fine finished thread is required. On a thread for what might be called a commercial finish, and where quantity rather than quality is desired, high speed steel has the advantage. High speed steel thread chasers are not recommended for cutting brass, for they have a tendency to stick to the work.

Fine finish and highest speed do not go together, and where threads of fine finish are required carbon steel chasers must be used. All grades of carbon steel are of much finer grain than high speed steel.

The next item is an answer rather than a query, and is presented in letter form as follows:

In the July, 1920, issue of your joyful little publication is stated the fact that you know of no satisfactory method of measuring internal threads except with standard plug gauges. Undoubtedly this is the most generally adopted method for production work, although there is a formula and method which is given in Communication B 523 of the Gage section of the Bureau of Standards. The formula is as follows:

$$E = M - \frac{\cot a}{2n} + G\,(1 + \text{cosec. } a)$$

in which E=pitch diam.; M=measurement between balls; n=No. of threads per inch; G=diam. of balls; a=half of included angle of thread.

Instead of wires as used on plugs or external threads, balls of the diameter best suited to the size of the thread are used and the measurement between these made with gage blocks in combination with a slide parallel in order to secure the correct adjustment and pressure.

I think that this is the formula which the party desires, but is practical only in exceptional cases on ring thread gauges.

Next on the list comes this query: "Why should two chasers do the cutting while the others of the set do none?" Here is the answer:

Uneven chamfer is most likely the cause of this unequal cutting. Prove the chamfer even from the cam slot. The grinding should be done from the keyway and not from bottom or top of chaser. The cam may be out of true, and cause the condition; or, possibly, the distance from the cam slot to the cutting face of the chasers is not true.

Lastly we have this one: "A 1½-inch collapsing tap does not always close up, and often tears the threads."

It is probable that the threads, when tearing, clog the chasers and hold the tap stiffly, so as to interfere with its collapsing properly. Our suggestion is to try grinding the chasers with a slight hook, which will, no doubt, stop the tearing of the threads. The cam spring in the tap may have become weakened, and this would account for the tap not closing. A weakened cam spring could readily be replaced by a new one.

The beauty of presenting these excerpts is that the very problems under discussion may help you solve a similar difficulty.

A movement is under way at Windsor to maintain a floating hotel to relieve the lack of hotel accommodation in the border cities. President Bourke, of the Great Lakes Transportation Co., declares his willingness to moor one of the company's vessels where it would be easily accessible to travellers.

ONE OF THE SLEEPING ROOMS AND WASH ROOM IN BROWN & SHARPE APPRENTICE HOUSE.

Gears From a Purchaser's Standpoint

By D. G. STANBROUGH

IN a paper read before the American Gear Manufacturers' Assoc. convention at Detroit, the author deals with questions relating to personnel and organization, labor market, plant buildings, and equipment, in so far as these affect the gear-manufacturing industry. He next dealt with the fact that satisfactory gears from a purchaser's standpoint can only be produced as a result of conformity to good practice along the following lines: (1) Design; (2) materials; (3) forgings and castings; (4) heat-treatment; (5) machining; (6) hardening, and (7) inspection.

There are certain fundamental considerations of design, he said, that can be counted upon to produce good gears, although a partially satisfactory product may be turned out if all of these fundamentals are not strictly adhered to. The good features of gears are uniform sections and a tooth form which will meet all the requirements as to strength. The design must also take into consideration the practice of the plant in which the gears are to be manufactured. Take, for instance, the familiar cluster gear used in automobiles. This cluster can be made from the blank with integral gears, or can be made with three integral gears and a fourth gear riveted or fastened to a flange. In the first case, a certain method of cutting has to be employed, and there will be unquestionably a considerable loss from warpage in heat-treatment. In the other case, the loss from warpage is reduced, but, on the other hand, considerable grinding is introduced, and a nice fitting job is necessary. The decision as to the design should naturally rest with the practice of the shop. Good gears can be produced by either method, and the one to be adopted depends more upon which is in vogue than upon any technical consideration as to the results that can be obtained with either method.

Method of Mounting

Another big thing which needs careful attention in designing gears, if satisfactory results are to be obtained, is the method of mounting. The best cut gear that can be made will not give satisfaction unless properly mounted. Many a noisy gear would not be noisy if it were run on quiet bearings. The mounting of gears should be such as to take care of the stress incident to the pressure angles. The shafts should be stiff, the mounting rigid, and the bearings as close to the centre of the load application as it is possible to make them. In designing a gearcase, strains should receive careful consideration. The manufacturer cannot be expected to turn out a finished product which conforms to the customer's specifications unless the product be given at least fair conditions under which to operate. Much time and energy can be saved by giving more consideration to the design of gear mounting before the manufacturing work is undertaken. Too little attention has been paid to the mounting of gears by designers in the past. The manufacturers can do the purchaser a favor by pointing out the deficiency in design before undertaking contracts.

Materials for Gears

In selecting the materials from which gears should be manufactured, the conditions under which the gears are to be operated should be considered. First, those subjected to practically no stress and very little wear should be made of bronze, cast iron, untreated bar stock, and aluminum. Second, if the service will produce great wear, but not severe stresses, the material should be "straight" carbon steel, and should be carburized. Third, if the gears are subjected to extreme wear and considerable stresses, they should be made from forgings of alloy steel, and should be carburized. Fourth, where severe impact and other stresses are involved with a normal rate of year, high-grade alloy steel forgings should be used, oil-treated and not carburized. Fifth, where the gears are to be subjected to extreme wear and extreme stresses, they should be made from self-hardening steels which have been forged.

Castings and Forgings

No serious difficulty is encountered when the gear blanks are cast, although it is important to keep the sections uniform in order to guard against shrinkage cracks, especially in the case of gear blanks made from steel castings. With cast iron it is important, in order to obtain long life, that the combined carbon be high, and that the metal be cast so that the blank will be chilled, thereby retaining a sufficient quantity of the carbon in solution. The blanks should not be so hard that they cannot be machined without annealing, the most satisfactory results being obtained with a scleroscope hardness of about 35; the combined carbon content should be between 0.30 and 0.50 per cent. No particular difficulty is experienced with bronze and aluminum castings.

The forging of gear blanks represents a considerable problem. The temperatures at both the beginning and end of the operation should be held within certain well-defined limits, according to the forging temperatures of the steels being used. High temperatures produce burnt gears, which sometimes can be used only after an expensive corrective treatment process has been employed. A low finishing temperature results in cold strains which, when relieved in heat-treatment, reveal cracks, seams, and fissures. Another phase of the forging of gears is in regard to the type of forging machines employed. Generally speaking, the flow lines of the metal in a forging should be at right angles to the forces applied to the gear teeth while in operation. It follows, then, that a gear that is flat can be produced under a drop-hammer, while gears having bosses, and those in which length is the predominant feature, can best be produced by a forging machine. The size of the hammer has an important bearing on the subject; a large gear cannot be satisfactorily forged under a light hammer, as the time required to close the dies permits the gear to cool and results in too low a finishing temperature.

Preliminary Heat-Treatment

Practically all gears that have been forged should be given a preliminary heat-treatment before machining, particularly those gears that will be subjected to great stress and that must be practically free from distortion after hardening. On mild steel this initial heat-treatment consists simply of annealing or normalizing. Normalizing the steel eliminates whatever stresses have been set up in the forgings and renders the gears suitable for machining. On the alloy and high-carbon steels the normalizing treatment is not sufficient. Gear blanks made of these steels are first quenched from a suitable temperature and then drawn sufficiently to enable them to be machined.

Machining of the Blanks

In manufacturing gear blanks it is important that the surfaces be held parallel and that they be machined true with the holes in the blanks. In the author's experience, broaching will produce a straighter hole than reaming. Gears that have splined holes should be machined from the splines, both in the blanking and cutting operations. It is also essential that the pitch line of the gear be concentric with the hole.

Probably the simplest method employed for locating the gears when finish-grinding the bores and faces is the one in which the work is located from the periphery. Another method employed is that in which the gear is located from the root diameter; and still another method—and the most difficult of the three—is that by which pins carried in the chuck contact with the gear teeth at the pitch line. Locating a gear from the root diameter is the most practical method. When this practice is followed it is necessary to finish-cut the root diameter. This method also enables the locating pins in the chuck to be made stationary for each size of gear, which is

WELDING AND CUTTING

Possible Economies in the Application of the Oxy-Acetylene Process

THE following article, by the secretary of the French Acetylene Association, on possible economies in the application of the oxy-acetylene process, is both timely and of great interest.

The cost of blowpipe welding has increased to such an extent compared with other methods of making joints that there is a risk of its remarkable progress being stopped. An investigation to determine what methods should be adopted to avoid this reveals the fact that economies of all kinds can be realized in the application of the process. With the present day methods economy in one way or another will give a total saving of 20, 30, 40 and even 50 per cent.

In the first place consider the raw materials which at the present time are so costly. How many firms call for a test of their supplies of oxygen and carbide? The majority of users of the process assume that there is only one quality of carbide, and consequently the question of whether the carbide is good, bad, or indifferent never crosses their mind. Suppose, for example, carbide is bought yielding 200 litres of acetylene per kilogramme of carbide instead of 300 litres, unless a repayment claim is made based on the analysis, the cost to the buyer is increased by one-third, to say nothing of the impurities in the gas, which accompany inferior carbide, or the additional manipulation necessary.

Regarding Oxygen

With regard to oxygen, in France it is guaranteed to be 95 per cent. pure, but very few firms test to verify this degree of purity. Suppose, for example, it is not more than 90 per cent. pure, a fact which would not be discovered when using a welding blowpipe, the buyer's costs are increased by at least 12 per cent.; of this figure 5 per cent. is loss in purity of the gas and at least seven per cent. due to the reduction in the speed of welding. The welds produced are also distinctly inferior.

The utilization of carbide and oxygen calls for economy. Certain acetylene generating plants will, through excess production and bad design, discharge into the atmosphere one-quarter and even one-third of the gas developed. With others the generation is accompanied by intense polymerisation, as is shown by the colour and nauseous odour of the residue; the loss in this case may be from 20 to 30 per cent. Again, there are avoidable losses in charging and cleaning, using wrong sizes of carbide, and wastage of small carbide. There may be small leakages in the apparatus, at the joints and valves, which in the aggregate amounts to considerable waste and represents appreciable loss.

In the case of oxygen, how many firms check the cylinder contents or possess an accurate pressure gage for this purpose? Suppose, for example, the pressure is 100 or 110 atmospheres instead of 120, there would be a loss of 10 or 15 feet of oxygen per cylinder, which, at the present price of oxygen, might mean considerable loss. There may be a leakage at an oxygen valve, or through a defective regulator, or through porous flexible hose, or through a defective union or connector, consequently it is not difficult to use almost 200 cubic feet of gas where 100 cubic feet should be used. There is also considerable loss in the return of empty oxygen cylinders. Frequently, owing to lack of supervision, carelessness or negligence on the part of the welder, cylinders are returned containing gas at a pressure of 80 pounds per square inch and upwards. It is not uncommon to find full cylinders mixed with empty ones.

The Blowpipe

Consider next the blowpipe. This offers a very large field for economy. It is well known that the consumption of oxygen and acetylene should approach equal volumes and that the average for well-known blowpipes will work out about 1.2 to 1.3 cubic feet of exygen for each cubic foot of acetylene. But if consumption tests are made in any workshop it will be found that the figure is nearer 1.8. In other words, there is a waste of half a cubic foot of oxygen per cubic foot of acetylene used; thus, with a blowpipe consuming 20 cubic feet of acetylene per hour there is a waste of 10 cubic feet of oxygen per hour, in addition, the speed of welding is reduced and the welds inferior.

The rates of the consumption of oxygen to that of acetylene does not entirely depend upon the type of blowpipe used, it also depends upon the proper maintenance and the working condition of the blowpipe, and, in a very large measure, upon the pressure at which the oxygen is used, a pressure which is invariably too high.

With regard to the actual welding operation, there is the case where a blowpipe of insufficient power for the work in hand is used, as a result of which the welding speed is too slow, even for the expenditure of gases. If the blowpipe is too powerful it is necessary to raise the flame in order to avoid holes; in this way heat is wasted and, of course, oxygen and acetylene in addition to the loss of time.

In one workshop we found for a given class of work that 12 feet per hour was the speed of welding, whilst in another works doing exactly the same work the number was 18 feet, and the welds were good and carefully executed. This result, which shows an economy in gases and labor of 33 per cent. is simply due to the better preparations and better execution of the welds.

Welding Backward

It has been shown that the new method of executing welds known as welding backwards and which can be applied to an immense variety of steel welding, varying from ⅛ to ½ inch in thickness, will give an economy in labor and gases of at least 25 per cent. How many firms have studied this important development and applied this method?

There are also important economies to be shown when well designed and appropriate jigs are used, when the edges are well prepared, and when the comfort of the welders is studied. The blowpipes which burn in the air whilst a welder turns the work, searches for a welding wire or, perhaps, rolls a cigarette, are wasting unnecessarily the principal materials which, as we know, are very dear.

The objection might be raised that it is an easy matter to describe methods of economising but in industrial application the proposals become more or less theoretical. Our answer to that is that the figures and methods of economising spoken of have been obtained and applied in the welding firm of Girel & Co. This firm employs 500 welders and consumes about 150 tons of carbide per day and 110,000 to 130,000 cubic feet of oxygen per day. The carbide and oxygen are analyzed on their arrival and the contents

of the cylinders verified on receipt and in returning them; the yield of the generating plant, tests or leakages, the overhaul of blowpipes and regulators, are made a regular part of the work. Records as to the oxygen used daily by each welder are kept, so that it is an easy matter to determine the consumption of acetylene and thus to fix the cost per foot of welding, and then to constantly endeavor to lower the cost by a better utilization of the flame, using better devices for assisting the welding operator, etc. As a part of excellent collaboration on the part of the several foremen, the foreman welders, and the welders themselves, and the excellence of the materials used and the general organization, we have obtained results which, in these days, would be considered remarkable. As an example, in manufacturing certain articles which other workshops were also engaged upon, the cost of oxygen and acetylene was only one-half of that of other important firms. The production for the same amount of labor was double that of other firms, and finally, after Government inspection of the work, there were no rejections.

This is only one example where great economy has followed the paying of attention to the points indicated. It is certainly time that all firms engaged in welding operations paid more attention to the economical side of the process if only from the point of view of the quality of the work.

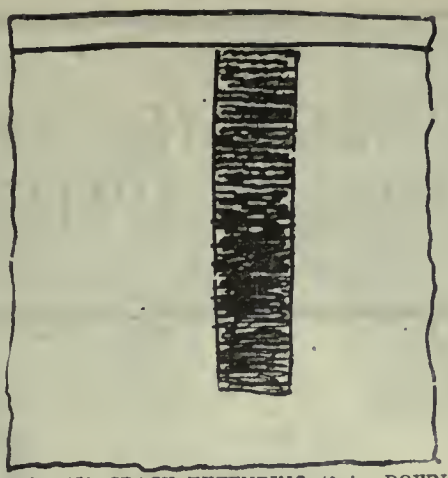
AN UNUSUAL WELD

A repair job of interest to all engineers was recently carried out by means of the electric arc welding process to the main engine cylinder of the steamer Chippewa.

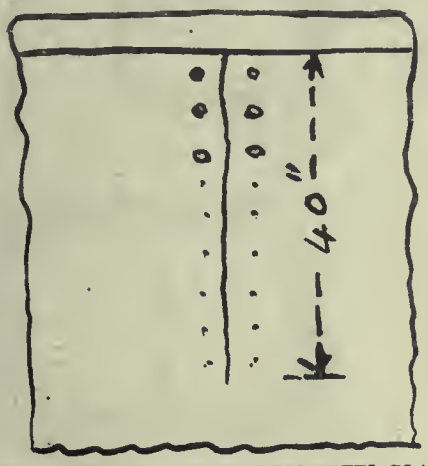
Our readers will be familiar with the Chippewa's old-fashioned beam engine or "walking beam," as it is sometimes called. Needless to say the engine only has one cylinder, so that when a vertical crack some 40 inches long developed in the cylinder wall during the busiest part of the season, something had to be done about it. The cylinder is 5 ft. 6 in. in diameter by 12 ft. long, and carries a working pressure of 60 lbs. per sq. in.

After consultation with the Lincoln Electric Co. as to the possibility of successfully welding the crack, it was decided to proceed with repairs as quickly as possible, by means of a method which has been very successful in repairing large iron castings subject to heavy working stresses.

Holes were drilled down each side of the crack, and steel studs were screwed in and cut off about 3-4 in. from the cast iron. By the time the last stud was in, the Lincoln Electric Co's. motor truck carrying the portable electric welding outfit was on the dock within 20 feet of the Chippewa's engine room. The cables were connected up and the welder went to work to weld those studs and the cast iron of the cylinder into a solid mass of metal. Twenty-four hours later the job was complete and shortly afterward the Chippewa steamed out into the lake for a trial trip.



SHOWING CRACK EXTENDING 40 in. DOWN FROM TOP OF CYLINDER, STUDDED READY FOR WELDING.



FINISHED WELD RESEMBLING STEEL PLASTER ABOUT 1 IN. THICK, APPLIED TO OUTSIDE OF CYLINDER WALL FOR FULL LENGTH OF CRACK.

Note:—It was found that this method of welding had the effect of drawing the edges together and closing up the crack as the weld was made, from the bottom up.

The weld was found to be quite tight and appeared to be a perfect job. The Superintendent Engineer deemed it advisable, however, to make assurance doubly sure by re-inforcing the weld with two steel bands placed right around the cylinder.

Electric arc welding has been used extensively of late along the water-front in Toronto for boiler and hull repairs but this is one of the first local instances that has come to our notice of the use of the process for a major repair to a large and important iron casting.

There was recently put into service in America, at the Government League Island Navy Yard, Philadelphia, a crane which is described in the General Electric Review (U.S.A.) as the largest hammer head type fitting-out crane which has yet been built. The crane is approximately 250 feet high overall and can handle a 350-long-ton load at 115 feet radius, and a 50-long-ton load at a 190 feet radius. The maximum lift of the main hook from the deck of the pier on which the crane is located is 145 feet, but the drum holds sufficient cable so that the hook can be lowered 25 feet below the deck of the pier, making a total lift for the main hook of 170 feet. The 50-ton hook has a maximum lift of 180 feet. The total length of the swinging jib is 300 feet, of which 100 feet is on one side of the centre line and contains the machinery house and counterweight, while the other 200 feet is on the opposite side of the centre line and contains the runways for the trolley carriages.

HEAT TREATMENT OF STEEL

In a paper recently read before the Detroit Convention of the American Gear Manufacturers' Association, Mr. G. W. Yale advocated the use of the electric furnace for the heat treatment of steel. A lead bath or an ordinary coal or gas fuel furnace has, he observes, a very great heat capacity, and is accordingly but little cooled down when the material to be heated is placed in it. The consequence is that small parts heat up more quickly than large ones and the result is often disastrous. He considers for example, the case of a "chunk" of steel 4 in. in diam., with a spur 1-4 in. thick which is put into a big furnace or lead bath at a temperature of 1,500 deg. F. The bath or furnace is chilled but slightly, and the spur being small in volume heats up rapidly and gives a large grain structure, whilst the heavier portion becomes heated more slowly.

Steel expands when heated, both when the temperature is below and when it is above the transformation point, but at the actual transformation point it contracts, and hence if different portions of a mass of steel under treatment pass the transformation point at different times, distortions are likely to occur, and there may be cracking and failures.

If the same piece of steel be heated in an electric furnace of small heat capacity, the furnace is chilled when the steel is placed in it and the temperature can then be raised slowly, in which case both light and heavy portions of the article under treatment pass through the transformation point at the same time.

Although the cost of electric heating per B.Th.U. developed, is much higher than in direct heating by coal, gas or oil, the cost per B.Th.U. usefully employed is not very different, since, with electric heating, the heat is generated just where required, whilst with other systems of heating 60 per cent. to 80 per cent. of the total heat passes off up the chimney. The labor costs are also markedly different since with direct heating the total cost of the labor includes that expended in cleaning off scale, straightening warped pieces, or grinding operations, which are said to be unnecessary when the heat treatment is conducted along the lines which Mr. Yale advocates. Taking the case of such articles as automobile gears, it is stated that two men can, with the electrical method, turn out 2,000 lb. and 2,400 lb. of treated metal per day.

DEVELOPMENTS IN SHOP EQUIPMENT

CONTINUOUS MILLING MACHINE

THE machine about to be described is the product of the Newton Machine Tool Works, Inc., Philadelphia, Pa., and is known as the first model continuous milling machine. Figs. 1 and 2 will give readers a good idea of its general appearance without work or cutters, and starting from this point we will discuss a few of this machine's features as spoken of by the makers.

The column and base are a one piece casting in order that all strains resulting from bolted joints may be obviated. The table is circular in form, with special provision for mounting the various forms and types of holding devices as is required for the rapid machining of a variety of parts. It will be observed that this table is adjustable upon the base in order to provide for the proper positioning of the jigs carrying the work in relation to the cutters, in order that the work may be placed upon the smallest possible radius, and utilize the least possible diameter of cutter.

It will be realized the advantages of

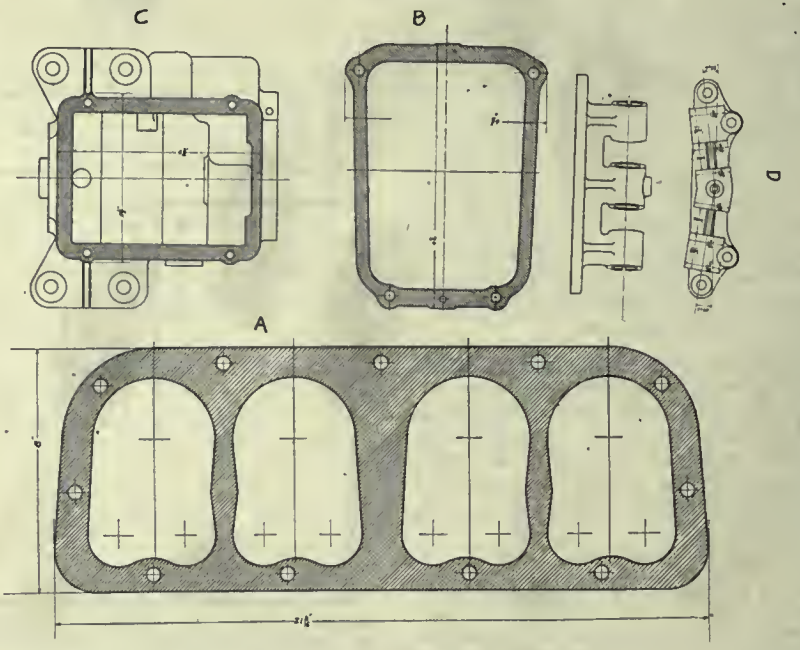


FIG. 4—SKETCHES OF WORK DESCRIBED IN TEXT.

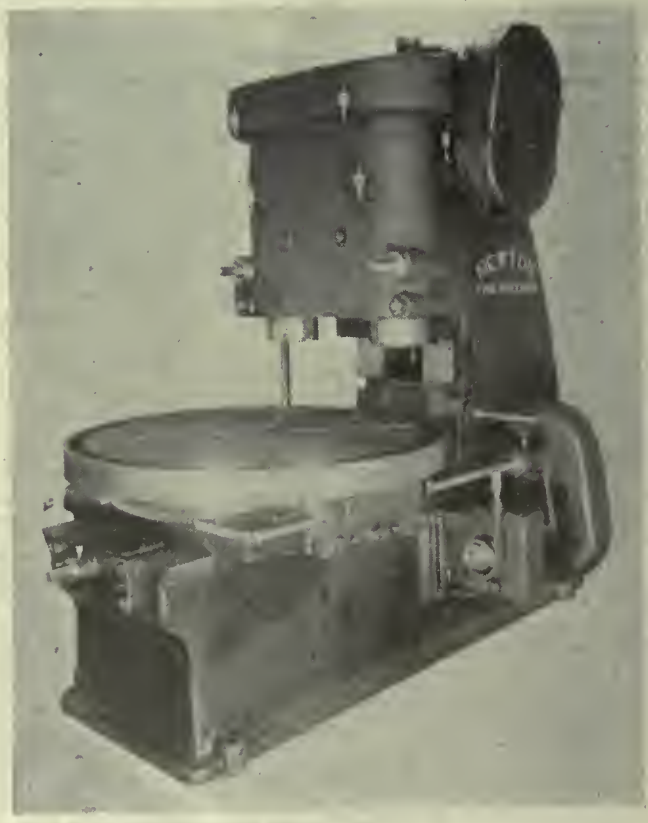

FIGS. 1 AND 2—SHOWING THE MACHINE FROM BOTH SIDES.

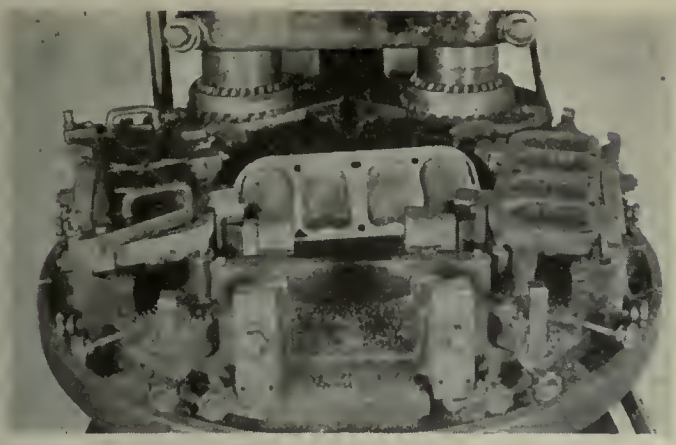

FIG. 3—THIRTY PIECES PER HOUR ARE COMPLETED AT THIS OPERATION.

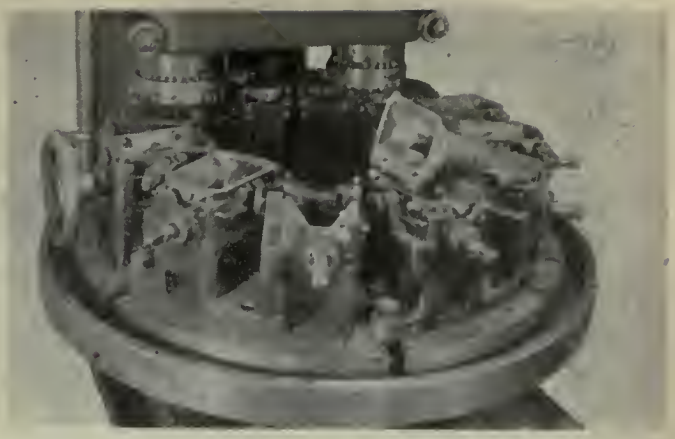

FIG. 6—MACHINING GEAR CASE COVERS. NOTE FIXTURES USED.

positioning, from the viewpoint that the production is largely controlled by the number of pieces removed to one revolution of the table; hence, it is essential that these be placed with the least possible space between them, whether this space be in the form of an open block, or whether it be in a wedge shaped form, due to the pieces being laid out with too much angularity in relation to each other, and this can only be overcome by having the table adjustable as described. These tables may be 24-inch, 36-inch or 48-inch diameter on their working surface, in addition to which they are surrounded by a pan for draining lubricant when working on steel.

The adjustment to the table provides for the machining of pieces with a flat surface, or machining pieces of a forked character, in which a gang of cutters are used. The rotative movement is controlled by a fixed feed, so that there is no possibility of the operator increasing or decreasing the production of the machine, as any holding device passing the loading station will immediately attract the attention of the man in charge of the section, and in addition to this, as the functions of the machine require so many stations per hour to pass the loading station, that number of pieces must be loaded and unloaded or a clear explanation made as to the loss. There is, however, a provision in the feed mechanism by which this rate of feed can be increased or decreased by those in authority.

The spindle head is equipped with two spindles, each of which is individually adjustable for setting the cutters to gauges. The left-hand spindle is used for the roughing operation, and the right-hand spindle for finishing. The distance between centres of these spindles varies from 22½ inches on the largest machine, to 13 inches on the smallest machine, so that very long pieces can be machined with the roughing operation complete before the finishing cutter starts on the same piece. Demonstration has illustrated that this is perhaps the most accurate method of machining parts in quantities, because any wear or any variation in the machining occurring, due to inequality of castings, is absorbed in the finishing operation, and owing to the small amount of work to be performed by the finishing cutter, accuracy of both finish and dimension are maintained with infrequent grindings of both cutters required, due to this condition. Secondly, with the ability to pick up and obtain accuracy with the finishing spindle, it permits of the running of much higher cutting speeds and feeds than otherwise practical.

The makers state as follows: We have frequently taken pieces 6 inches x 20 inches in length out of the jig and laid them on a surface plate to find that they will hold six papers, and also that it will be impossible to at any point enter a thickness gauge of .0015, indicating that we not only secure a high finish but we do not have any warpage of the casting, or any digging in of the cutter on the leading side. The speeds of the spindles are controlled in the same manner as the feed described above, and a

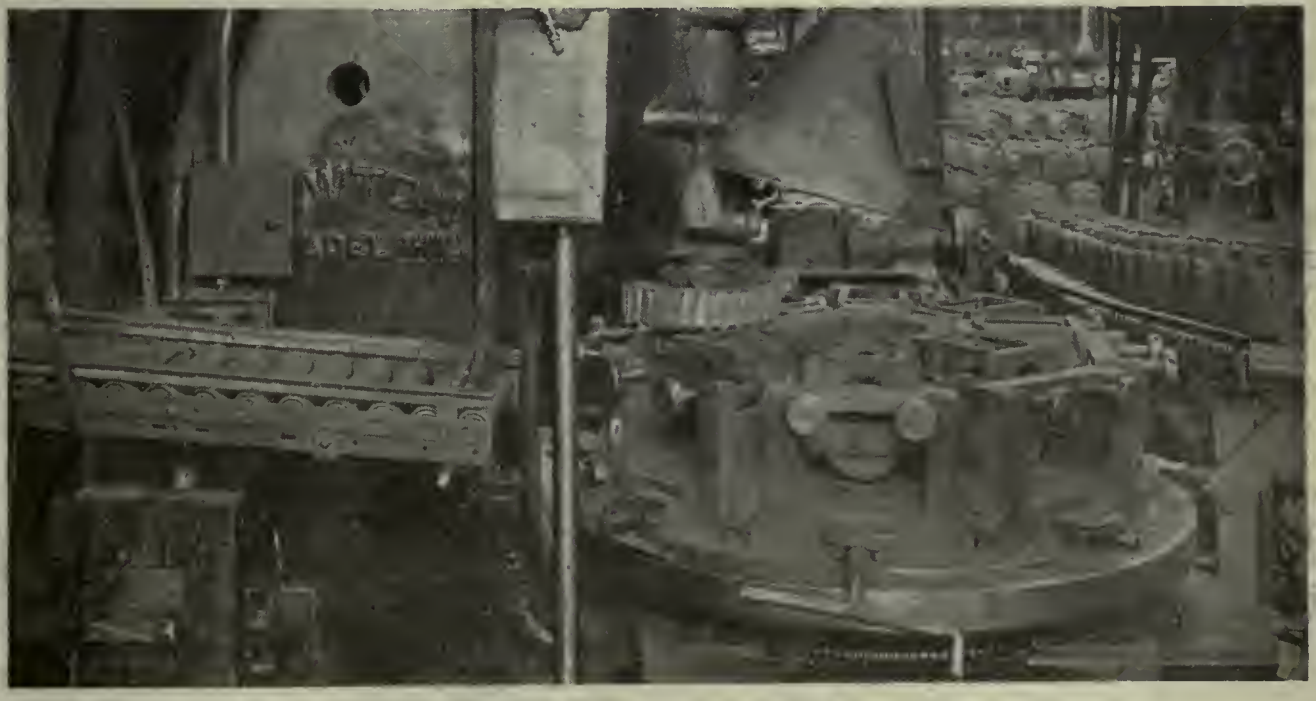

FIG. 7- FIRST OPERATION ON GEAR BOX REFERRED TO AT FIG. 6.

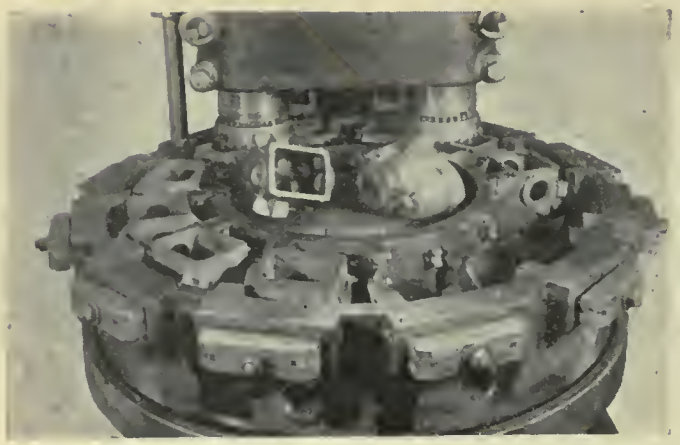

FIG. 9—A BETTER EXAMPLE OF JIG CONSTRUCTION.

FIG. 10—MACHINING BRACKET AS SHOWN AT "D." SEE FIG. 4.

large element of the success of this work lies in the design of the worms and worm wheels used in the driving of the spindles these worms and wheels being made over a method peculiarly our own, and as the result of very exhaustive experiments carried on in the year 1914.

The housing, or head, carrying the spindles is adjustable on the column, and this again is a necessary element of this type of machine, in order that the holding device may set as flat or low to the table as the casting itself will permit, and the head adjusted downward provides for the minimum extension of overhang to the cutter and spindle; whereas, if this head were a rigid frame having a fixed distance above the table, it would be necessary to build a jig up into the air in order to bring the work to the cutters, instead of bringing the cutters to the work as is done in this design.

One of the big elements entering into the high rates of feeds and speeds that these machines maintain is the manner in which the work presents itself to the cutter. As the work is revolving it will, as you will realize, present a constantly changing angle to the cutter; thereby providing the benefits of the shearing action and overcoming the flat, heavy cutting which is obtained by operations maintained on a straight line.

The machine is made with all driving gears hardened, enclosed and running in oil, with the result that the combined elements of a heavy, rugged frame, exceedingly large bearing surfaces, large diameter spindles, a well balanced drive, providing a surplus of power, means the complete elimination of vibration, and some of these machines have been in operation for several years without having required any replacements or any stoppage other than for changing holding fixtures or cutters.

Fig. 3 illustrates an automobile cylinder head chucked from the rough casting by the gauge appearing in the photograph. In other words, the casting is placed in the holding device, the gauge set in position and the casting then adjusted to the gauge which locks the casting from the combustion chamber, in order that a uniform area of combustion is obtained. The production of these pieces is 30 per hour. The sketch Fig. 4 at A, gives the outline dimensions of these castings. Fig. 5 shows the same casting, and is intended only to illustrate the statement made relative to the angularity of the pieces and the closeness with which they are chucked one to the other. In this instance, owing to the water connection appearing at one end of the casting, it would not be practical, even though the circle were increased, to reduce the space appearing between each casting. Were the casting free of this water connection, then a larger number of pieces on a larger circle would increase the production, because the idle time, as indicated by the gap between the castings, would be omitted.

Fig. 6 illustrates a casting which is a gear case cover or lever stand of an automobile. Observe how closely these pieces come to each other, so that there is no loss of time in the cut leaving and starting from one piece to another. The sketch B, see Fig. 4, shows an outline of this piece, production of which

FIG. 8—THE GEAR BOX AT ITS SECOND OPERATION.

is 120 per hour. Both these illustrations will clearly show the relationship between the size of the cutter and the spindle, so that some comparative idea may be formed of the ruggedness of the entire apparatus.

Fig. 7 shows method of chucking gear box referred to above for the first operation, and Fig. 8 illustrates method of chucking the same gear box for the second operation. The production of these boxes runs from 100 to 125 per hour.

Fig. 9 shows a better construction of jig for a similar piece, which is made of malleable iron, the production of which is 100 per hour, this piece being show at C, in Fig. 4. The photograph Fig. 10 shows method of facing bosses on a bracket. This bracket is shown at D, in Fig. 4, in which you will observe there are six faces to be machined, three of which are on one line, and three on another line, at an angle to the first, so that two operations are required to complete this piece. At a feed of only 4 inches per minute, a production of 30 pieces per hour is provided. Much greater production could be obtained if required. It will be readily understood that it would be quite impossible for one operator to do anything like this amount of work by spot-facing the bearings in place of the process described. These various views are used as typical illustrations of two different classes of work applicable to this type of machine, but they are also used for a variety of other operations, which are too numerous to describe in an article such as the present one.

NEW THINGS IN MACHINE TOOLS

OT-STEEL BENCH LEGS

The Angle Steel Stool Company, of Otsego, Mich., are placing on the market a special line of steel angle bench legs made in various heights and adapted for many purposes. The legs are flat on top and are of pleasing design and where extra width is required the sections may be placed back to back. All legs are finished with a baked-on coat of green enamel.

STATIONARY HEAD DRILLING MACHINE

A heavy-type drilling machine with a stationary head has been developed by the Sibley Machine Company, of South Bend, Ind., which is particularly adapted for production work. Apart from the fixed head the machine is very similar to the sliding head type of the same company. Back gears are of the sliding type and are operated by a lever. Feed change gears run in oil and all gears on the machine are completely enclosed with suitable guards. The machine may be furnished with special equipment if desired. The floor space is approximately 23 by 63 inches.

20-INCH DRILLING MACHINE

The 20-inch drilling machine of the Silver Manufacturing Machine, of Salem, Ohio, has recently been re-designed, the features of reconstruction including a new style of frame and an increased capacity beneath the drill spindle, the maximum distance being now 28 1-4 inches to the base plate. The spindle is fitted with S. K. F. ball thrust bearings. The machine may be obtained with either hand or power feed and can be supplied for both belt and motor drive as desired. The machine is also built in gangs of two, three or four spindles.

HERCULES PRESS-BROACH

The 15-ton arbor press and vertical broaching machine formerly made by the Hercules Machinery Company has recently been redesigned and it is claimed that the number of operations capable of being performed by the new machine has been increased. The operating ram has a stroke of 18 inches and may be driven either by belt or individual motor. The machine is fitted with a knee that has a vertical adjustment of 14 inches, and this knee may be removed and replaced by fixtures or conveyors, if desired. A safety pin is provided for over-load of the press. The travel of the ram is governed by means of an automatic trip.

AUTOMATIC ACETYLENE GENERATOR

An automatic acetylene generator that is primarily intended for use in oxy-acetylene welding, cutting and lead-burning, has been developed by the Imperial Brass Manufacturing Company, of Chicago, Ill. The apparatus is mounted on a truck, making a portable unit. The operation of the generator is automatically started when the gas begins flowing to the torch. The pressure is also under automatic control, and by means of a blow-off is maintained always below 15 pounds. The gas is passed through a water seal as it passed from the generator. Several sizes of the apparatus are manufactured.

NEW TYPE OF GUARD

The Modern Tool Company, of Erie, Pa., are now equipping all their machines with a new type of guard that has the advantage of affording visibility of all the movable parts, at the same time adequately protecting the workmen from coming in contact with any of the mechanism. The guards are of the phantom type and are made of expanded metal and secured to the frame of the machine by means of angle irons. Hinged portions are provided to facilitate the oiling and cleaning of the different parts of the machine protected.

FROM A PURCHASER'S STANDPOINT

(Continued from page 333.)

an advantage. Although the method of locating from the pitch line has given satisfactory results, it is probably just a little less accurate owing to the fact that warpage produced in heat-treatment will have a greater effect at the pitch line than upon the root or at the top of the teeth. Locating the gear from the periphery is open to the objection that greater accuracy is required in the primary operations in order to get satisfactory results. Further difficulties to locating from the periphery arise from the fact that burrs are often thrown up, which, if not removed, will cause errors.

Final Hardening of Gears

All gears made from carburized stock, and, as a rule, all oil-treated gears, are finish-machined before final heat-treatment. Although considerable difficulty may be experienced in the final heat-treating process, the "hump" method developed by Leeds and Northrup Company, Philadelphia, Pa., is one of the most satisfactory of the various methods which may be employed. Distortion in gears is dependent to a large degree upon heating. The range of heating, together with the establishment of constant quenching temperatures, can be relied upon to solve problems in gear distortion which formerly were believed to be uncontrollable. To a large measure the solution of these temperature-control problems is due to the development of the electric furnace.

Methods of Testing Gears

After the purchaser has satisfied himself that the various manufacturing conditions required to produce a satisfactory gear have been complied with, attention should be directed to the final inspection process. The hardness is of much importance, but it should be remembered that tests such as the scleroscope furnishes are comparative only, and that standards of hardness to suit the service to which the gears will be subjected should be established. The limits of these standards should be such that the gear will withstand a reasonable amount of wear, but it should not be so high as to make it brittle. The work of inspection, then, so far as hardness is concerned, is to determine whether the gears are within the limits allowed.

After the hardness test, each piece should receive a rigid visual inspection under good lighting conditions for the purpose of discovering cracks and seams which may develop during the final hardening operation. With reference to inspection of tooth form, a rolling fixture in which the gears are mounted at the correct centre distance and rolled with a master gear is recommended. A hand-rolling fixture will give better results than a power type. The gears should be tested for backlash and for conformity to the dimensions specified by the established practice of the manufacturer.

British and American Trade

THE extent to which United States producers of steel, finished and semi-finished, have captured the Canadian market can not be appreciated without a study of the figures.

If one cares to go back a few years to 1883 it will be found that the United Kingdom and United States were doing about an equal share of the business of selling steel goods to Canada, there being not more than a couple of hundred thousand dollars' difference in the figures.

But see what has happened in recent years. Taking the figures for the period ending March 31 in each case the years 1913 to 1920 show this:—

Year	Steel Imports From U.K.	Steel Imports From U.S.
1913	$10,394,276.00	$106,471,913.00
1914	10,132,543.00	85,729,001.00
1915	7,402,894.00	55,462,477.00
1916	3,950,000.00	71,459,771.00
1917	4,683,103.00	119,754,365.00
1918	4,081,681.00	154,113,633.00
1919	5,912,768.00	154,426,648.00
1920	5,167,100.00	144,669,402.00

How did this come about? The Canadian Association of British Manufacturers, in a little book published for the purpose of increasing British trade in Canada, points out that there was a great opportunity in 1896 following the coming of preferential tariff treatments in Canada for the British to expand their business here. The article in question points out that "United Kingdom manufacturers never had a better opportunity to capture the now vast trade of this Dominion than that which presented itself in the years immediately following. But what was the result? Most pitiable! Not only did they not hold their established proportion of trade, but by a want of confidence in Canadian integrity, by neglect, by a pursuance of the lines of least resistance, by failure to adequately and substantially support accredited representatives, actually drove the business into the mills of their shrewd and more aggressive competitor."

The result, according to the same source, can be summed up as follows: In 30 years British trade with Canada in steel goods increased 50 per cent., while that of United States increased 1,250 per cent.

American firms have learned the value of publicity in dealing with the Canadian market. Their goods are advertised, and they conform to the wants of this country. British firms have a good opportunity now to study the Canadian market, our ways of buying, the conditions and acceptances on which we finance, and many other things, an observance of which would make a great deal of difference in the trade return figures of months and years to come.

Could You Fill This?

HERE is an advertisement that appeared in a Toronto paper this week. It occupied two inches and carried a heading sufficiently conspicuous to make it noticeable:—

> We have an opening for a man at present as Assistant Superintendent of a large plant in Canada. Desire Canadian, and a technical education would be beneficial, but not absolutely necessary. If you feel you have made good, and your record will stand investigation, it may pay you to get in touch with us. Should have general knowledge of manufacture of mechanical lines. We are looking for a real good man of proven ability, who could take full charge when necessary. No others considered. State experience, age, present connection and approximate salary desired. Negotiations confidential.

Now, these openings keep cropping up now and then. Perhaps not very often, but a glance at the papers shows quite a number in the course of a month.

The position may be offered to-day, or six months from now. That depends on a good many things.

If it were put up to YOU to-day, what would YOU do? Could you walk into the office, make application and state your case, knowing that you would be able to fill the position?

Or would you have to do, as many others, watch that chance go to someone else, and be content to stand back and comment that some chaps had all the luck, and that none of the breaks came your way.

The day of study has not passed, neither has the prospect of dividends for the man who burns the midnight oil.

The openings go to the men who are ready to take them. They seldom wait months or years for a man to get ready.

If you are prepared it may take a long time for the big chance to come, but if you are not prepared, you may take it for granted the big chance will never come.

Guaranteeing the Price

THE practice of cutting rates in piece-work shops is coming to be one of the things that will soon be known only as a memory. It was done in many places. One job comes up from years past of a plow factory where the rate had been set at "so much per" on the polishing operation. Polishing plows is not easy work, at least it was a husky man's calling at that time. When the boys in the polishing room had dusted off enough shares and consumed enough dust to chalk up around $2.25 per day, the new price schedule was posted on the wall, and it became apparent that $1.85 was the limit.

It was another way of punishing a man for working hard.

Under that system the wise piece worker got a job and knew when he was at the limit. He jogged along, killed time and at the end of the day had an output that could be cashed in for $2, or thereabouts. It was encouraging laziness on the part of the men.

All over the country we have shops now where the prices are fixed after a careful study—they are guaranteed for a given period or until such time as there may be an alteration in the operation itself. Production men claim they are getting better results this way than from any other system they have tried.

Must Specialize to Get Mass Production

"THE day of the all-around mechanic is done for with the possible exception of some of the jobbing establishments, and I believe that the change is the best thing for the men themselves and the only possible thing for the shops. The general training still has its place and should not be neglected, but it should only serve as the good groundwork for the development of our specialists."

That, in brief, is the idea of Mr. R. W. Gifford, superintendent of the Massey-Harris Co. plant in Toronto, and what is more, Mr. Gifford can bring out arguments to convince a man that his line of reasoning is right. He is willing to admit, though, that the thorough training is desirable, and that it may be necessary for the shops themselves to bring about a training school of their own in order to keep up the supply of men who shall have a good groundwork from which to draw the specialists and maintenance men of the future.

Where the Move Started

"The specialized shop started with the automobile business," stated Mr. Gifford, in discussing this matter with Canadian Machinery, "and from that it has spread to every other concern that feels the necessity for mass production. There is no other way in which a business can be maintained and face the competition of the world. For instance, I suppose if you were to go into our shops here, and we gave you enough iron or steel, hammers, a fire and anvils or places to work, you could, in time, by sufficient hammering, turn out a plow by yourself, but we couldn't sell it, as there would have been too much cost attached to it, and the time consumed in using all the equipment would also amount to a very great deal.

Nor does Mr. Gifford believe that specializing is a bad thing for the men. "The man who has the all-round training, if he has work that calls for it, can find full scope for every bit of it, but if his occupation calls for another line of specialized work, he may find his previous training a handicap. That may seem a queer statement," continued Mr. Gifford, "but it is a fact that if a plant where production counts for much is looking for a foreman or an executive or a production man, they have to look to these specialized shops now. A shop is no use, neither is its immense equipment, unless that shop is getting production. Now that is the standpoint from which we must start to talk about the specialist from either the angle of the management or of the men. In districts where there are no specialized shops, the manufacturers find that they are handicapped because the men in that district do not understand how to go about it to get mass production."

Even in the Tool Room

Even the sacred precincts of the tool room have been invaded, and in that sphere, where the all-round man was supposed to revel in his wide application of the ways and devices of long training, to-day we have the specialist.

"In the tool room of the Massey-Harris plant," continued Mr. Gifford, "we have some 75 men. We doubled the staff there some time ago, and it may be that we will make large additions to the force there later on. It pays to do it. In that force of tool makers they are nearly all specialists now, and it is hard to see how it could be done otherwise. There is the man working on dies, some on those that are to work on cold metal, others on those that will come in contact with hot metal. Others specialize on jigs and fixtures, some on grinding. What is the result? We get men who we believe are the best to be had on these special jobs, and from these men it is only natural to hold that we get the best work that can be secured."

In Other Lines as Well

That everything is being specialized, and that machinist trade can be no exception, is the view of the superintendent. "Suppose there were something wrong with your eye, to whom would you go to have it fixed, to an ordinary doctor or to a specialist? The specialist, of course, and which one of these men would get the most money for his services? Once more the specialist. When a man goes to college he gets a good training. He may take degrees. But after all that is over, what happens? Does he hang up a sign saying that he has gone through all these subjects and is prepared to give advice on any of them. Not a bit of it—he specializes. He goes in for engineering, for construction, or for any one of many lines. And does it pay us to specialize? Not long ago we finished a die worth over $3,000, but it will save us $15,000. We turned out one die for making seats for agricultural machinery, and out of these seats we punch enough washers to pay for the thing."

How About the Men?

"But where do the men come in on this specializing?" was asked.

"Guarantee the prices paid in a shop and the men will benefit by the specializing and by the system that will get mass production," replied Mr. Gifford, without any hesitation. "There are plenty of shops where the men have been afraid to let out because they knew that once they reached a certain limit the price on the job would be adjusted so they would have to work harder to get up to their former mark. The result of this policy—a mistaken one, I believe—has been that the full production possibilities of many departments have never been let out. Guarantee the prices, and the same plant will turn out a great deal more work, and it will be better for all concerned."

Mr. Gifford has had a good opportunity to study this point in a number of plants. He can draw on numerous cases to prove his points. "Here is one case that will show the advantage of specializing. One man is in the erecting department, and he has a certain part to bring together. There is a nice little knack in the thing, and he has been at that a long time and can turn out a great deal more work than any other man. He is making more money than a good many tool makers. An all-round mechanic might not make much more than his salt on that job, but the ability of that man to do that little job quickly and thoroughly is a mighty good thing for the man and a good thing for the shop. I can think also of another man on a hammer. He is a specialist on that particular operation. Formerly in that shop they were afraid to pull out because they had a pretty good idea that once they got past a certain limit the price would be cut. The promise was given that the price would stand and the man let loose. There are seasons when he makes four times as much as he used to, and the firm is willing that he should go ahead and make as much more. He specializes on that work and he knows the rate will not be altered. The result is production, and I know of no surer way to get it."

In the Foundry, Too

Mr. Gifford holds that it is possible to specialize all the way through, and it is being done in the foundry. "In our shop out of 150 molders there are probably not more than six or seven general purpose men. The rest are bench, floor men, squeezer, match plate, etc. The use of molding machines tends to this method, and it is the best for all concerned. We do not want a man to work on a dozen things. We want him to do one thing well, and the better he can do it the better will our product be and the more money he will earn. There is one department where shops have not yet got operators in sufficient numbers who are thoroughly adept, and that is in the automatics, especially in operators for automatic screw machines. I do not believe that, as a general thing, the output of this class of machine is much more than fifty per cent. of what the machines are capable of doing. Firms making these machines would find it to their advantage to train operators."

(Continued on page 345)

MARKET DEVELOPMENTS

Steel and Tool Prices Have Not Given Way Yet

Some Few Concessions Being Made, But as a General Thing Conditions Remain Unchanged—Demand for the Delivery of Steel on Order is Just as Insistent as it Was Six Months Ago.

SOME price revisions on machine tools have come out during the week. One maker has announced a schedule that follows the lead of the automobile industry, while the Canadian end of one British firm has given out a revision which makes a few changes, but leaves the list a little higher than previously. New York reports that buyers there feel that the machine tool market belongs to them, and they are reported to be getting some odd concessions that were not available a few months ago. That is about the extent of the price changes, and when taken against the entire field, it is hard to see where much progress has been made in the matter of price reduction.

Men who have covered the field in Canada for steel interests say, that with the possible exception of the automobile business, there is no let-up whatever in the demand for steel, and buyers are just as insistent as ever in wanting to get their orders filled and delivered at their plants. New business is not coming in rapidly to the steel men, this probably being accounted for by the fact that it is not yet possible to get rapid deliveries, although there is a great improvement in this direction.

The departments that specialize in small tools claim that there is more competition going on now than for some months past, and the trade is being thoroughly canvassed in this district to get any business that may be going. Prices, though, remain firm and there is no complaint of any price concessions beyond those generally recognized by the trade.

The scrap metal market shows no change at all. Dealers in most cases state plainly that they can be counted for the present as being out of the market unless there is something offered at quite a price concession. The big users have not returned to the point yet where they will buy, and until that takes place there is going to be continued stagnation.

BUYERS WAIT IN HOPE THAT THE PRICES MAY BE MORE FAVORABLE

Special to Canadian Machinery

MONTREAL, Oct. 7.—Trading conditions are more or less affected by the movement that is becoming general throughout the States and Canada towards an adjustment to lower price levels on many commodities, both industrial and domestic. Business, in consequence, has reflected the conservative policy of consumers, many of whom are adopting a waiting attitude and holding off buying until a decline is announced. It has been stated that increased European production of steel goods has reacted on the Canadian mills and export from here has been on the downward grade.

Lower Prices Anticipated

The trade is undoubtedly facing an early revision of steel prices, but it is difficult to get anyone to commit himself as to the time such adjustment will take place. It is becoming increasingly clear that the demand for finished products is gradually falling off, and with the mills and foundries in a better position to increase production, the result of such conditions can only mean that any change in prices would be in a downward direction. Shipments of American steel are better in volume, and owing to past demand and existing requirements, the greater portion of this material is going direct to the purchaser, but current demand is not adequate to absorb all the steel that is being produced, and with dealers reluctant to stock at present prices, the movement of steels can only continue by removing the barrier of excessive high costs by adjusting the normal level of steel prices to a point where consumers will come into the market with more confidence and assurance of a stabilized condition. It is thought that a concerted effort to lower the cost of steel materials would have a good effect on labor, and remove some of the factors that at present are disturbing many branches of the industry, pave the way for better co-operation between industrial classes, and enable the manufacturing industries to engage in many activities that have been suspended or curtailed owing to the impossible conditions that have intervened.

Metals Quiet But Steady

The movement of metals is of a quiet character but the volume of sales is relatively light, due largely to the conservative attitude of buyers in taking on only sufficient for immediate requirements. The prediction seems to favor lower prices but the existing market is comparatively firm. Lake copper is the only metal showing a change, a decline of one cent, leaving the present quotation at 24 cents per pound.

Supplies Moving Steadily

Coupled with the announcement that business is light, machine tool dealers are living in expectation of lower prices on many of their lines. Many are unable to figure out just how a cut of any magnitude could be reasonably made but admit that this action may take place at any time. The inquiry for equipment is quite light and below normal for this time of the year but the movement of supplies continues in such volume as to indicate that industrial activity is well maintained though easing up in some directions. The better shipments on tools and small equipment reflect a lighter demand, but the cost of production and transportation are still so high that any early drop in prices must be based on trade requirements rather than on manufacturing costs.

Foundry Iron Higher

Apart from steel and cast iron scrap the old material market shows little signs of activity and the general movement of all metals is below normal; as a matter of fact, present business is

duller than it has been for many months. Export of scrap is practically nil and current trading is largely of a local character. The possible downward trend of prices on manufactured products has apparently affected trading, and in consequence the buying of materials has been held up to some extent. The curtailment of production in some industries has likewise been felt in scrap circles and demand is proportionately lighter. The quotations obtaining on all lines are subject to adjustment to suit individual sales but those listed are a fair average of those prevailing in this district. The general situation shows firmness with machine cast iron quoted at $36 per ton, and stove plate at $28, these prices representing an advance of $4 and $1.50 per ton over those of last week.

NOT A REQUEST FOR CANCELLATION

That Is Report of One Machine Tool House — Demand Keeps Up For Steel

TORONTO.—Another week has passed since the talk of price cutting had its start, and still it is hard to find any sign of its striking the machine tool, iron or steel market. Some of the dealers are authorized by their principals to guarantee their prices for some months to come, and in nearly all cases buyers are protected, and they would get the benefit of any reduction that was made.

"We have had no requests for cancellation from any of the business that we have on our books," was the report of one firm to-day. The dealers would be the first to get wind of any such movement in this country, and it would be forwarded from them to the makers. Much of the machinery is sold under the non-cancellation understanding, but the fact that there has been no request for cancellation in any case looks as though there were no doubters in the manufacturing world here. As a matter of fact, as explained by one house to-day, most of the business booked is of a very reliable sort. Very few of the orders are in large lots now, and generally represent changes or additions to existing equipment, and they are not to be upset by any temporary setbacks.

In discussing the matter of prices, the resident representative of a large Old Country firm stated to Machinery that prices had been sent out just a few days ago from the home office. In some cases there was a reduction of a few pounds, and in others an increase. On the whole the prices seemed to have gone up a little. He did not seem to think there was any chance of British houses at present sending in machine tools at a lower figure than they were doing now. "What may take place in the future I don't know, and would not care to predict. There may be a number of influences at work that we know nothing about, and these may have much to do with the prices. For instance, were buying to fall off, or were there many cancellations, the makers might find that they were accumulating stocks, and money is not the easiest thing in the world to secure for getting out finished material right now. It might be that they would have to get rid of some of their stock in order to secure money. In that case it would influence prices. Of course that is entirely suppositious, but I have seen things work out that way before."

The same dealer, when asked regarding the attitude of the buyer in Canada, stated that he did not believe that buyers were holding off in the hope of better prices. A new machine tool, especially of the labor saving variety, would pay its way from the start, and did not depend on the cheese-paring policy in matter of prices.

Hard After Business

Dealers selling small tools report that there is more real business hunting going along now than at any time for months past. "People are getting out to sell at a faster pace than they have been doing for a long time. Many of the stores here have been putting men on small tools and nothing else, and as a result we have to get out more." There is a lot of small business turning up, although there are few large orders coming into the market now. The National Railways have a specification out for a list of carbon drills, but otherwise the business is made up largely of small orders. There is no change in any of the prices."

Little Improvement

In some cases deliveries of steel are not so marked in improvement as they were a week or so ago. A representative of one firm has just returned from going over a good deal of the territory in this district. Speaking of the attitude of the buyers he said, "There is no let-up in the demand for steel. Apart from some of the automobile industries, and other lines that have contracts from them there is the same insistent demand for steel that there has been for months past. I can name a dozen places where I called where my reception was the same. It would run like this, 'Glad to see you, come on in,' and in a very short time it would be around to this, 'You remember that order we had booked with you some time ago? Wish you would take that up and give it your personal attention to see if there is nothing that could be done to get that shipment to us.' Of course there were some variations from that request, but that was the feeling all over. There is certainly no falling off in the demand for steel, apart from the one line to which I referred to at the outset."

The Scrap Metal Market

"We are practically out of the market for the present," is the way one of the large yards stated its position this week. "We have been expecting the turn to come for some time, and believe that a day one way or the other is going to make the difference. If the market remains weak now for a few days longer, or if it breaks, I believe that there will be business resumed, but it will be on a lower plane than we have been used to."

The unsettled conditions following the price cutting move seems to have something to do with the scrap market. Many of the users are continuing to draw on reserves, believing that they

POINTS IN WEEK'S MARKETING NOTES

Pittsburgh reports that not very much progress has been made toward low prices for steel, though it admits that the general sentiment has become much stronger on this subject.

—

The cancellations that have come, through the automobile makers to the steel mills, released a tonnage that has been taken up by other industries.

—

Information from Pittsburgh for steel at fairly quick delivery is quoted this week at 3 cents for bars, 3.10 cents for shapes, and 3.25 cents for plates. Some predictions are that these prices will yield, but there is no evidence of it yet.

—

There is very little attention paid to lower prices talk in the machine tool market, although there are reports of one maker having issued a new price list.

—

One of the largest machine tool houses in this district reports this week that so far they have not had a single appeal for cancellation of any business on their books.

—

One Old Country house doing business in Canada has forwarded new lists on machine tools. Some of these show increases, others are down a little, but as a general thing the whole list is said to be a little upward.

—

Some of the small tool dealers report that there is more competition at the present time in the Toronto field than there has been for a good many months past.

—

The scrap metal market is waiting for a turn that will bring some business its way. Some of the largest yards state frankly that for the present at least they are out of the market. The large users are not buying, and dealers show no tendency to take on material for stock.

will be able to make replacements at a lower figure. It all tends to keep the buyers out of the market and the dealers do not feel as though they would be justified in going ahead and buying for stock.

TOOL MARKET IS THE BUYER'S NOW

New York Looks For a Quiet Period For the Remainder of the Year

NEW YORK, Oct. 7. — The recent trend of price developments points to rather quiet conditions in the machine-tool trade over the remainder of the year at least. This is a buyer's market, and it is but natural that buyers should be considering the possibility of lower prices on all of the products they buy, including machine tools. As yet there are no indications of a downward movement in machinery prices, but concessions are being made by sellers that were not necessary a few months ago. For example, some sellers, at the request of buyers, are guaranteeing their prices for a period of three to six months.

While the outlook for the remainder of the year in the machine-tool trade is for very light buying there is a deal of optimism as to next year's prospects. The railroads are expected to come into the market eventually, and some sellers have fixed the beginning of substantial railroad buying as about January 1. Railroads are known to be working on budgets for 1921, and if the financial situation warrants it is believed likely that they will buy quite heavily of shop equipment, which they are known to need very badly. Some of the railroad shops are antiquated, and a considerable part of the shop equipment of some of them is in a bad state of disrepair. It would seem as if buying of machine tools for the railroad shop cannot much longer be deferred.

At present, however, there is practically no railroad buying in the East, though a number of roads have made fairly good purchases at Chicago.

BRITISH PRICES ON THE WAY DOWN?

Galvanized Sheets Show a Definite Rrop of $7 Per Ton For Export

British prices show a downward tendency, particularly for export. A definite drop of $7 per ton is noted in galvanized sheets, which are now about 6c a pound at to-day's rate of exchange.

A wide divergenee in wages is indicated in puddling. The current British puddling rate, expressed in American money, is $8.25 per ton, while the last settlement at Youngstown, Ohio, established a rate of $18.02 for September and October.

AUTO CANCELLATION NOT GOING TO BATTER DOWN STEEL SCHEDULE

(Special to Canadian Machinery)

PITTSBURGH, Oct. 7.—In itself, the iron and steel market shows very little by way of new developments and not much progress has been made, visibly, towards lower prices. General sentiment, however, has become much stronger on the subject of substantial price declines being necessary. Undoubtedly the declines in automobile prices have had a great deal to do with molding public opinion as to prices generally. It seems that the public takes particular interest in whatever occurs in the automobile field. In last report it was noted that Ford, Franklin and Crow-Elkhart, had reduced prices. To the list may now be added Locomobile, Studebaker, Mercer and Overland. One may well conclude that a general and substantial decline in automobile prices is in progress, no matter what technical denials individual automobile makers may give to the press. The reductions are not sporadic, the names on the list of reductions thus far being typical of altogether too many classes of machines. Locomobile, Franklin, Studebaker and Overland each fall in a different class.

Steel and Automobile Prices

The steel industry is quick to refuse to admit that steel price declines can be connected with automobile price declines. It is commonly admitted in the steel trade that steel price declines must occur, the common view being that independent prices will recede to the Steel Corporation level, whether in a few weeks or a few months, and it is also the common view that the Steel Corporation prices will not be reduced. Some independents may have to cut under Steel Corporation prices to regain trade lost by what some buyers have not hesitated to call profiteering practices. The steel trade wants it to be understood, however, that the automobile trade itself cannot force down steel prices. It is admitted that the automobile trade was in large part responsible for the particularly fancy prices for prompt deliveries of steel that obtained early in the year, but it is asserted that the trade's power to put prices down is by no means measured by its influence in putting prices up earlier in the year, when automobile and part makers bid for prompt deliveries when the mills had already sold their product.

As to possible declines in Steel Corporation prices an impressive comparison is made, showing that from the Steel Corporation's standpoint automobile makers can have no argument that since they have reduced their prices the Steel Corporation should reduce its prices. The comparison takes an automobile that has been selling at between $2.000 and $3,000. The reduction in price on this movement might be $150, or $300, or even $400. Less than one gross ton of rolled steel, in the form in which the average steel mill sells steel, is represented in that automobile. The Steel Corporation's rated capacity is 16,200,000 tons a year, of products weighed in the form in which sold. A fair production can be taken at not under 15,000,000 tons. The common shares outstanding amount to about $508,000,000, so that $15,000,000 would represent $1 a ton on a year's output and would also represent a three per cent. dividend. The corporation certainly would not reduce prices to the automobile trade and keep them up to the railroads, to investors putting up bridges, buildings, etc., and to other buyers, hence a horizontal reduction in all prices is the only thing that could be considered. A reduction, therefore, that would be equal to a three per cent. common stock dividend would amount to less than $1 in the mill cost of the steel entering into a $2,000 or $3,000 automobile. In other words, the steel mills cannot help the automobile trade to recoup when it reduces prices of automobiles.

Another item that dissociates the automobile price reductions from the steel market as it is made from day to day and week to week is that the automobile trade is not in position to offer orders of any consequence at this time. Many of the automobile makers have contracts running to the end of this year, with the prospect that on account of reduced consumption deliveries will run into the new year. General Motors is commonly understood to have a contract running through next June, covering considerable parts at least of the requirements of its various subsidiaries. If there is such a contract it is with the Steel Corporation and at the Industrial Board prices, since the corporation has sold to domestic trade at no other prices since the schedule became effective March 21, 1919, and an automobile manufacturer can hardly complain about Industrial Board prices.

Two Steel Markets

There used to be three steel markets, the Steel Corporation set of prices, a schedule of prices, not entirely definite, at which certain large independents were selling to regular trade for extended delivery, and a wide range of prices representing prompt deliveries, charged chiefly by smaller mills that kept their order books relatively clear. The last named market has now practically disappeared. One can, as a rule, secure rather prompt deliveries at the prices formerly ruling only for somewhat extended or delayed deliveries. That market is substantially unchanged. It is represented by 3c for bars, 3.10c for shapes and 3.25c for plates. In time these prices will doubtless yield, but there is no distinct evidenee that they have yielded thus far.

Last week the American Pig Iron As-

sociation, composed of merchant furnacemen from a majority of the producing districts, held its monthly meeting at the William Penn Hotel, Pittsburgh. The prevailing, practically the unanimous, sentiment at the meeting, derived from information obtained from customers, was that a general industrial depression is impending, to exhibit its full force in the first quarter of the new year, with greatly reduced consumption and production and materially altered pig iron prices. The atmosphere of that meeting was as different as can be imagined from that of the meeting two months earlier, when several furnacemen were loudly predicting "pig iron is going to $50." It did go to that figure, in the case of foundry iron valley, Cleveland, Buffalo and Eastern Pennsylvania, but apparently the advance occurred chiefly because the furnacemen set out to get it. The furnacemen did not, however, get the orders. That was another matter. Consumers stopped buying. The trade has it that foundry iron at valley and Cleveland furnaces has now declined $3, to $47, furnace, but the decline rests upon even flimsier foundation than the preceding advance, as there was simply a small sale by a middle interest. No one doubts, however, that a buyer with an attractive inquiry could buy foundry iron at $47. The buyers do not want to pay that price and do not know what price they would pay. They are in position to wait until conditions become clearer.

PROSPECTS GOOD IN THE EAST NOW

Steel Mills Run at Capacity, and Output of Coal is More Satisfactory

Montreal.—Roy M. Wolvin, president of the Dominion Steel Corporation, left for Cape Breton to inspect the Sydney steel plant and the Cape Breton coal fields. From there Mr. Wolvin will proceed to Newfoundland, where he will make a tour of inspection of the corporation's mines at Wabana.

Reports from Sydney, Mr. Wolvin stated prior to his departure, were most encouraging, the steel mills there working to capacity, with the production at the coal mines showing a gratifying increase over previous levels, the output for September being particularly satisfying, although definite figures for the month had not yet been received at the Montreal office.

Mr. Wolvin's visit to the Wabana mines is in connection with the resumption of the export trade in iron ore, which during the war period and since the armistice, was reduced to negligible proportions. Mr. Wolvin states that it was hoped that the advent of 1921 would see a profitable trade in ore again established, the new overseas connections formed through the British Empire Steel Corporation being an important factor in the market for the ore.

PIG IRON TRADE

The iron market is developing soft spots. Valley foundry iron sold this year at $47 base. Basic is being offered at a lower rate by steel makers than the regular sellers. The prices are uncertain as there are few sales. Resale is the main feature of the pig iron market in Philadelphia. Very little interest is shown in next year's iron.

The market at Chicago is strong 1.75 to 2.25 silicon sold at $46 furnace. No iron is being piled, delivery being equal to production.

It is reported in Cleveland that basic could be had at $46.50 valley. The demand from stove foundries is unusually heavy, especially from the hot air furnace men.

The pig iron situation in New England has resolved into a struggle between consumers and furnaces to see which can hold out the longer.

The foundrymen almost without exception believe that the prices are going to drop, and refuse to buy beyond their immediate requirements. Eastern furnaces feel there is much uncertainty as to the future market. Requests have been received urging deliveries. New business has been small on the New York market during the past week. Prices remain unchanged for next year. Basic is wanted to some extent.

Owing to the feeling that prices are about to decline, consumers of pig iron are staying out of the Pittsburgh market. The foundry market shows a sagging owing to a sale last week of 700 tons of No. 2 foundry iron (1.75 to 2.25 silicon) to an Ohio consumer for last quarter delivery at $47 valley furnace.

No apprehension has been caused among Southern pig iron producers by the lull in the market. $42 for No. 2 foundry (1.75 to 2.25 silicon) is still the base. A few new inquiries are coming in but sales are very limited.

U.S. SCRAP METAL

Prices in the U.S. scrap market are declining slowly. Dealers are doing some buying, but consumers have reserves and are waiting for lower levels, refusing to be interested. On the Chicago market the consumers feel they can safely work on their reserves and expect to buy at a lower rate when forced into the market later.

The market in steel scrap shows weakness in New York, and though reductions have been made, demand is dull.

Dealers in the scrap market in Philadelphia attribute the present lull in the scrap market to the influence of price reductions in automobiles made by the Ford Motor Co. Shipments on contracts continue heavy.

Prices in all grades have declined in Boston. Dealers are unable to place tonnage except by making heavy concessions.

Practically no inquiries are being made for iron and steel scrap in Pittsburgh. Consumers are comfortably supplied. Prices are unchanged.

Many Buffalo dealers are anxious to obtain material to cover orders taken in the last month, but are holding back hoping for a break in the market. Lower prices are regarded as inevitable.

On the Cincinnati market, iron and steel scrap shows a lagging tendency, but some good orders for future delivery have been made and enquiries continue. Heavy shipments of recent purchases are being made.

BALDWIN PLANT STARTS ROLLING

The Tin Plate Mill Had Its First Trial Run a Few Days Ago

Baldwin's new $2,000,000 plant at Ashbridge's Bay has commenced rolling tinplate. Mrs, H. A. Cooch of Toronto at the opening threw the switch and the huge 1,500 horsepower electric motor set in motion the tremendous 160-ton main rope drive wheel, the largest flywheel yet used in Canada. The battery of eight mills commenced to grind. Then, cheered by hundreds of watching workmen, Toronto society women fed plates of white hot steel into the mills and rolled them again and again.

Mrs. A. M. Russel, wife of the president of the company, rolled the first sheet in No. 3 finishing mill. Other women who demonstrated their ability as steel workers were: Mrs. Roy Miller, Mrs. Fred Miller, Mrs. E. L. Cousins, Mrs. H. A. Cooch and Miss Church. Controller Maguire rolled the first plate through the roughing mills.

MUST SPECIALIZE

(Continued from page 341)

The whole shop organization is rapidly changing, and there should be a change in the training of men for the mechanical field to keep pace with the times. Mr. Gifford does not believe that the man who wants to be a success should think any the less of the fundamental training he needs. "Don't think that I am opposed to having the well-trained man. Every shop should see to it that an apprentice gets a thorough grasp of the fundamentals, and shops are not paying enough attention to this matter. We need these men, need them for maintenance, need them all the time to develop into branches that are almost passing out for want of well-trained men. Just one class need be mentioned, viz., the die-maker, and the real die-maker is becoming almost an extinct species."

Mr. Gifford has no apologies to make for the specialized shop. He firmly believes that it is the only way to secure results, and he is convinced that it is the best thing for the men and the best thing for the large industries—in fact he can see no other way in which they can be carried along successfully.

Producing Spindle Bracket for Upright Drill

The Machining of Such a Piece Must Be Followed Out With Great Care—Various Tools and Fixtures Used Are Shown and Described in Detail.

By FRANK H. MAYOH

MOST every mechanic is familiar with the spindle bracket of the upright drill, but perhaps few consider when sliding this spindle bracket up or down the dovetail slide of the machine what care must be exercised in machining this piece to obtain interchangeability of product consistently day in and day out on an economical basis. It is the purpose of this article to describe various tools used to this end and present in some detail the methods which have proved successful for accomplishing this as adopted by one drill press manufacturer.

This spindle bracket is shown by Fig. 1, the finished surfaces being indicated in the usual manner. It is made of a good grade of cast iron and on account of the deep slot cut in the dovetailed end must be allowed to season well during the operation between roughing and finish planing of the dovetail. In connection with the machining of this a list of operations are furnished, and these are shown in table form at Fig. 2, the first operation being to snag the casting, removing all fins and rough spots. The second operation noted is to rough plane the dovetail and the fixture illustrated by Fig. 4 is used for that purpose.

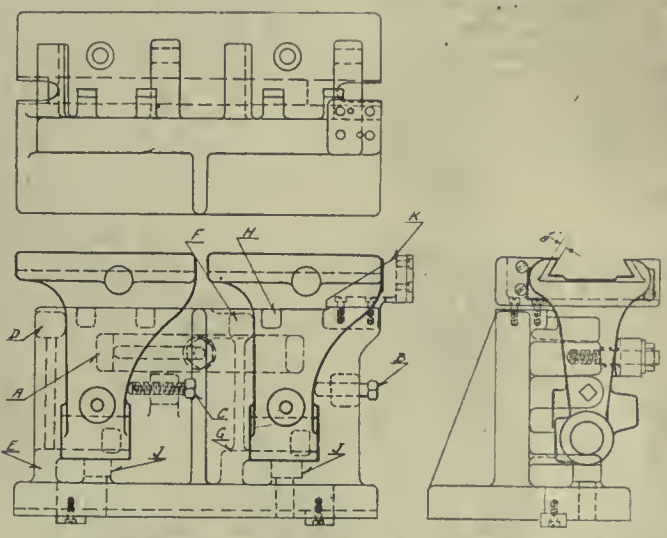

FIG. 4—FIXTURE FOR ROUGH PLANING DOVETAIL IN BRACKET.

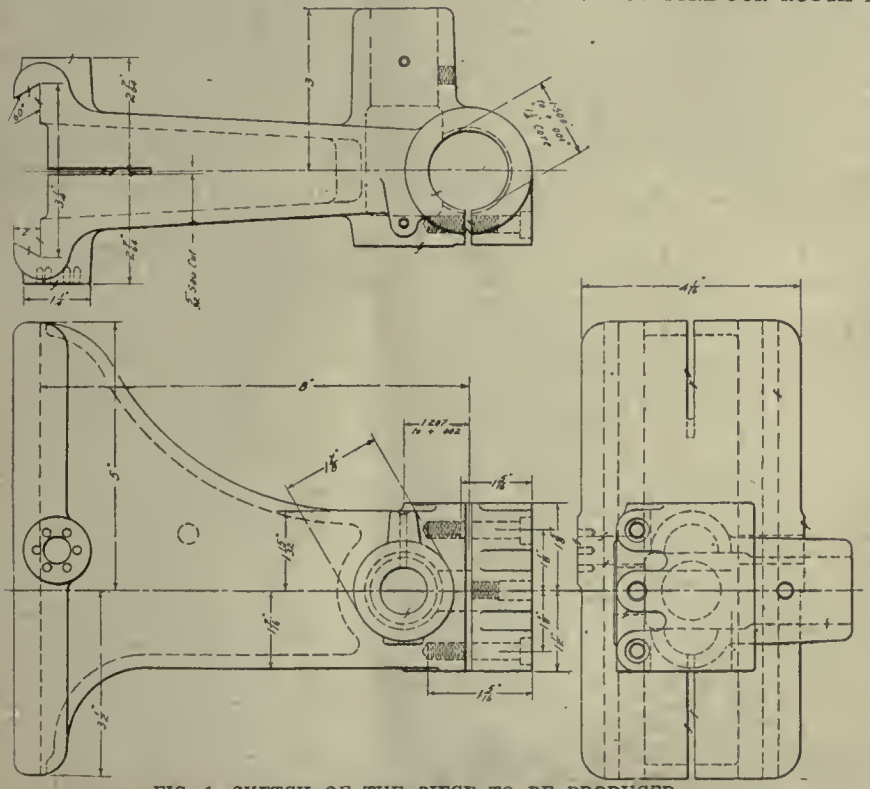

FIG. 1—SKETCH OF THE PIECE TO BE PRODUCED.

Referring to Fig. 4 this fixture is one of ten made to hold in all 20 pieces, two parts being contained in each fixture, and these fixtures being set in two rows on the planer table. The brackets are held in pairs, using a heavy clamp A, and set screws B and C, which hold each part respectively against lugs on the casting at D, E, F, G and H, thereby providing means for taking the thrust off the cut, and spots for squaring the work. To set the work, pins are employed at J, thus all brackets are located definitely from the boss, and as the fixtures are made to match, all the parts in a row are planed alike. On one fixture, at the start of each row, a bracket K is fastened by screws and dowels, and to this bracket is attached a steel plate cut out to match the dovetail of the work except that it is ⅛ inch large all round. By means of this, and 5-32 feeler gauges interposed

between the cutting tool and the gauge, the dovetail is planed accurately to size, allowing 1-32 to be removed by the finishing operation.

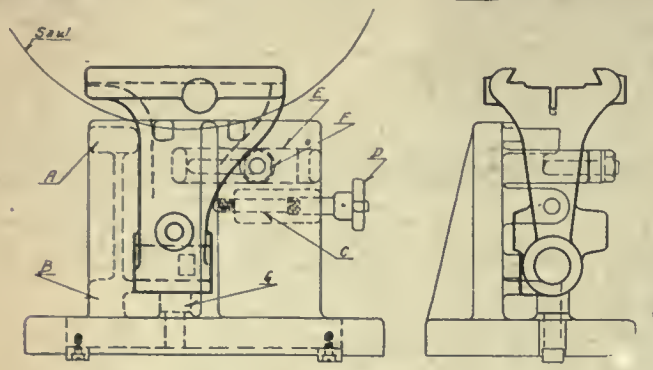

FIG. 6—FIXTURE FOR MILLING SLOT.

To illustrate the method of arranging these fixtures on the planer tabel a diagram, Fig. 5, has been drawn, and it will be noticed that between each double line are two numbers, 1 and 2, 15 and 16. These represent that two parts are held on each fixture, and the fixtures are set end for end in two rows, while at the right hand, as indicated, are the gauges previously mentioned for setting the planer tools.

For milling the slot between the dovetail, a fixture Fig. 6, constructed along the same general lines as those used for planing is provided, which, together with a large circular saw fed vertically into the work, cuts the slot across both ends at the same time. This fixture holds one part only. The work is held against lugs A and B by screw C, operated by hand knob D, while clamp E, tightened by the nut F, secures the work in place, which is also set on pin G. The fixture is held to the table of the machine by two tee bolts in the usual manner.

After cutting this slot it is found in practice that the casting springs out of shape, consequently they are set aside a short time to allow the castings to season before performing the finishing operation of planing, milling and drilling.

Taking up the work again to finish, plane the dovetail, which is operation four on the list; recourse is had to the same general practice as was used for rough planing. Twenty parts, set in two rows, with two in each fixture same as shown by Fig. 4 and 5 is the method employed, except that ⅛ inch feeler gauges instead of 5-32 are employed to set the planer tool, thereby ensuring that the dovetail on all parts will be substantially alike and finished correct to size, which size is tested to gauge, this gauge, together with the feeler gauges being shown by Fig. 7.

A drill jig of more than usual interest is shown by Fig. 8. This jig is for drilling and reaming the 1⅛ inch hole through which the drill press spindle slides, and this must line up with the dovetailed end of the bracket. Referring to the drawing, the work is pushed over the steel seat A until it rests on pin B, in which position it is clamped to the seat by means of the two clamps C and screw D. At the other end, two spring pins, E and F, are released against the boss, and these are clamped by screws G and H through the medium of beveled pins in the usual manner, while screw J and hand knob are used to bind the boss against the spring pins. Spring pin K is now released until it is pushed up and bears against the work, in which position it is clamped by screw M. The work is now securely held and we are prepared to do the drilling. This is accomplished as follows: cover N, hinged on pin P, is swung down into the position shown, and is locked there by nut and washer Q on hinge bolt R. This hinged cover contains fixed and slip bushings suitable for guiding the drill (which is of the three lip core drill type) and reamer size bushing, all of which together insures the production of good work in duplicate.

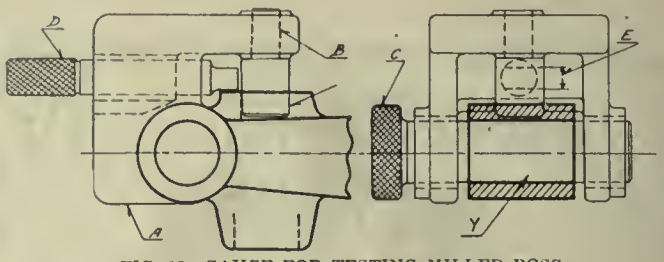

FIG. 12—GAUGE FOR TESTING MILLED BOSS.

To continue the drilling as called for in operation six on the list, the jig, Fig. 9, is employed. This has some of the characteristics of the jig shown in Fig. 8. inasmuch as part of the clamping is similar. The same type of dovetail slide A is used, over which the work is slipped while clamps B and C are used to tighten the work on this slide. Before tightening the clamps the work is also slid over stud D which fits into the hole previously machined. In this instance the work rests against the shoulder E on the stud D for locating it in the vertical plane, and thus supported, a wrench is used for tightening nut F, this securely holding the work in position, as all holes are crossways, and the thrust of drilling comes against the solid dovetail seat, or the stud D.

At this time the long hole G in the work is drilled from both sides, while the cross hole at the opposite end of the work is machined on the two diameters as necessary.

Following the drilling of hole G the bosses on each side of the work are faced. Solid steel bushings H and J are provided for guiding the spot facing tools, which are of standard make, while

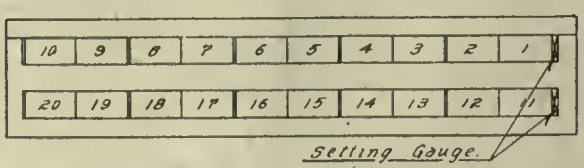

FIG. 2 SHOWS LIST OF OPERATIONS, WHILE FIG. 5 (SEE LOWER RIGHT HAND CORNER) ILLUSTRATES THE ARRANGEMENT OF FIXTURES, SHOWN BY FIG. 4 ON PLANER TABLE.

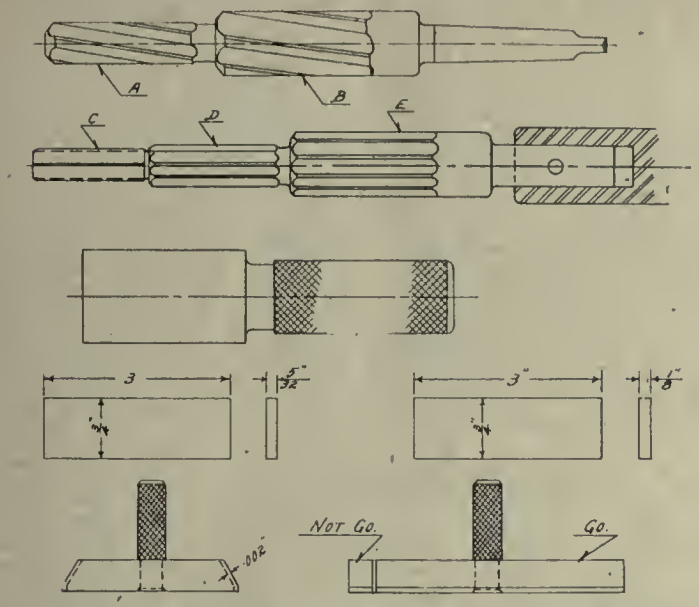
slip bushing K guides the 33-64 drill, this being transferred first from one side, then to the other side of the jig. Bent pins L are used to engage with pin M bushing Q, Fig. 9. Following this, the reamer shown is employed for finishing both of the holes true to size. This reamer likewise passes through both inch and a half hole which was machined at operation five, this being a wringing fit in the hole, as the same must be kept very accurate as regards size, and have a good smooth finish.



UPPER HALF OF VIEW SHOWS FIG. 10. THIS ILLUSTRATES A GROUP OF TOOLS USED WITH DRILL JIGS. LOWER PORTION OF VIEW SHOWS FIG. 7, WHICH ARE TESTING TOOLS FOR DOVETAILED SEAT.

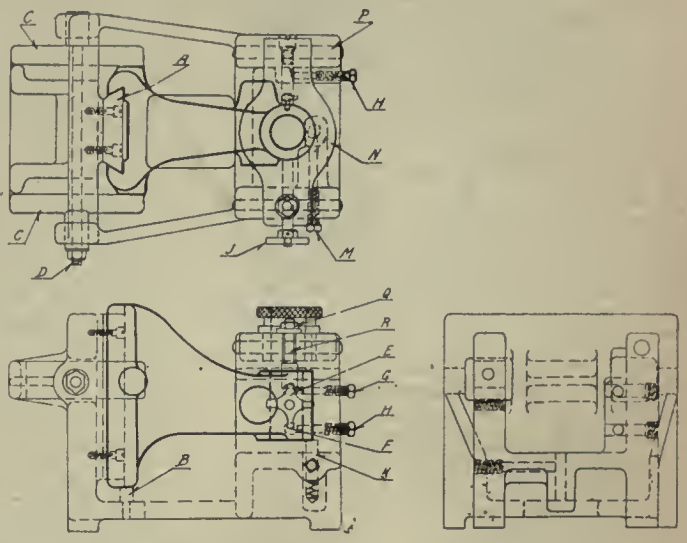


FIG. 8—JIG FOR DRILLING AND REAMING MAIN HOLE.

in the bushing to prevent the same from turning, this being a method quite commonly employed in jig construction. At the other end of the jig are bushings N, P and Q, which are used for guiding the first two tools, which are illustrated in Fig. 10, it being understood that this hole is cored, as the bracket comes from the foundry, therefore the first tool used is the drill A, Fig. 10, which is a three-lipped core-drill of two diameters, the smallest diameter being small enough to pass through the cored size of the large hole.

This means that both the small and large drill may be made to cut at the same time simultaneously, opening up both holes, the drill at this time being guided on diameter B, Fig. 10, in slipped holes, and the pilot end C, Fig 10, enters bushing N, Fig. 9, while reamer D finishes the small hole, and reamer E finishes the large hole. The diameter E, Fig. 10, is also guided in suitable slip bushing at Q, Fig. 9, which would be a good running fit for the reamer. Still referring to Fig. 9, the bushing P is hardened and ground, and is driven into the cast iron body of the jig so as to provide a lasting hole construction into which the slip bushings can be pushed for guiding the core drill and reamer.

A tapered socket is used in the drilling machine for holding the drill at this operation, while a universal drive connection is adapted for driving the reamer. The plug gauge shown in the lower portion of this illustration is for testing the

Now that all the important holes are machined, advantage of this fact can be taken during the remaining operations. It will be noticed in the following operations that the clamping methods are somewhat simple. Referring to Fig. 11 this is a milling operation which is performed on a vertical milling machine, and is noted as operation 7 on the list Fig. 2. In Fig 2 the bracket is slipped over the dovetailed seat A, and stud B. A long bolt C was placed through the hole where shown before putting the work in the fixture. This bolt was used to tighten the work, as by placing the wrench on nut D the work may be drawn together tight on the dovetail in the usual manner. The pin E is provided as a holding means to prevent the sutd

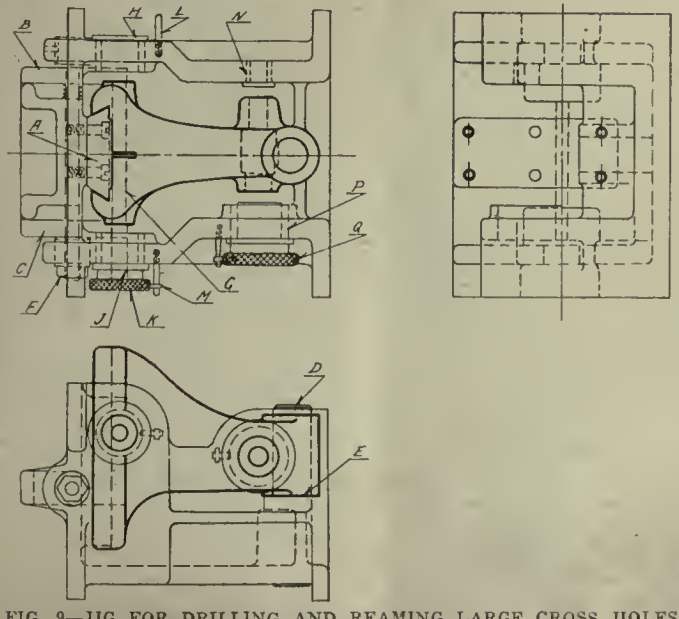

FIG. 9—JIG FOR DRILLING AND REAMING LARGE CROSS HOLES.

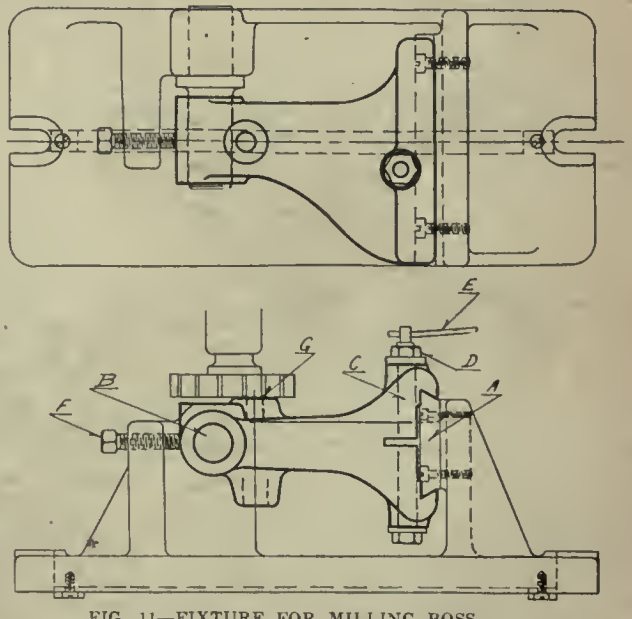

FIG. 11—FIXTURE FOR MILLING BOSS.

from turning while tightening the nut. At the opposite end of the fixture where the milling is done, a square head-screw F has been provided, and by tightening this against the boss on the work the same is securely held against the cutting stress, due to the feeding across of the large surface mill for finishing boss G.

After this milling operation it is necessary to gauge the distance from this boss to the large hole B at the end of the bracket. This is done by making a special limit gauge which is shown in Fig. 12. It consists of a body A, made of cast iron, in which is placed the stud B. The illustration also shows a knurled stud C. This is made a slip fit, and in use the gauge with the knurled stud removed is slipped over the work in the manner shown, the stud B entering hole X in the work. The knurled stud C is then pushed through the hole Y and into the holes of the gauge in the manner illustrated.

In this position the gauge is located relative to both holes previously reamed in the jigs. Another feature of this gauge is the knurled pin D. This is made of tool steel and is a snug sliding fit in the bushing. The pin is flattened on both sides at E, and with the gauge in place it is pushed over the boss on the work in the manner shown. If the flat side B^1 will go over, and the other flat A^1 will not go over the boss on the work, the same is milled correct, as the distance from the centre of the pin D is made three thousandths different, thereby providing a maximum and minimum to insure accurate work.

The remaining holes to be drilled are of a general routine nature requiring only such accuracy as to provide a reasonable degree of interchangeability common to machine tool construction. With this end in view the jig shown by Fig. 13, in unison with the base, has been provided for machining the six holes which are done at this time. This is referred to as operation eight on the list, Fig. 2. In connection with this jig, Fig. 13, it is to be noted that when drilling the series of four holes in the direction of the arrow, the base provided is not used as the work rests on the table of the drill press upon the surface A. The jig proper, B, contains a plug C, which is slipped into the hole of the work, while the surface on the jig D comes against the finished boss, being held thereto by the square head-screw E.

With the work setting on surface A, three holes F, and one hole M, are drilled. In machining the two screw holes, the drill used is tapping size for the screw, ignoring for the time being the counter-bore and tap size. In the hole between these two holes, which is for a headless adjusting screw, the drill used is first body sized to the desired depth, followed by tapping size the remaining distance. The bracket with the jig in place is now slipped over stud G in the base H, while the two holes J and K are drilled. Two pins L keep the work in its proper location on the base.

At the same time as the first three holes mentioned were drilled, hole M was also machined, using bushing noted by the same letter to guide the drill. Removing bracket entirely from the jig and placing the same on the table of the drill press, resting it on surface A, the two screw holes are drilled out body size and counter-bored, it being unnecessary to guide these tools as they will follow the holes previously drilled in the jig. All tools used for this purpose are stock tools, such as drills and counter-bores.

The simple jig shown at Fig. 14, consisting of two parts only, contains all the elements necessary for drilling the six small holes round the thirty-three sixty-fourths hole. This jig has a stud A, which fits into the hole of the work, and the jig itself B is made of steel. It is slipped over the boss and the wide surface X squares it in the bottom of the dovetail on the work. This feature in connection with the pin A locates the jig radially with sufficient degree of accuracy. By guiding the drill through the six small holes C this operation is completed in what is obviously a very simple manner. No. 28 drills are used for this purpose, and the work sets on the table of the drilling machine with blocks to keep it approximately level.

Operation 10 calls for tapping all holes. As a means of adjusting the bracket to a snug sliding fit on the drill press spindle the large hole has been slotted. This comes diagonally across the screw holes, and the last tool for this work is the milling fixture shown.

Referring to Fig. 15 the base A contains a stud B. This is driven in the boss on the base, and is securely held therein by the pin C. A long collar D with a hexagon nut completes the fixture. The collar D has a groove milled in it to allow the cutter to run into it, while the boss on the fixture also has a groove cut across it for the same purpose. This is why the stud C has a head on it with a nut to hold the base together when stud is in place.

In operation the bracket is slipped over the stud and is clamped in the manner shown by hexagon nut. One of the finished bosses resting on lug E locates the bracket radially on the stud. The fixture is clamped to the table of a horizontal milling machine in the customary manner, using two bolts, one at each end of the fixture, and a tongue in the T slot in the table to line the same up.

Referring once more to Fig. 2, the twelfth operation is burring or removing of sharp corners from the bracket. Operation 13 calls for scraping the dovetail. Operation 14, which is a perfunctory one, calls for assembling. For scraping the dovetail seat a special surface plate is required, but no drawing of this has been shown as it merely has a seat cut into it so that the dovetail can slide over this seat with about ¼ inch clearance, so that the bracket may be tested for angularity.

It will be noticed in following this sequence of operations that nothing has

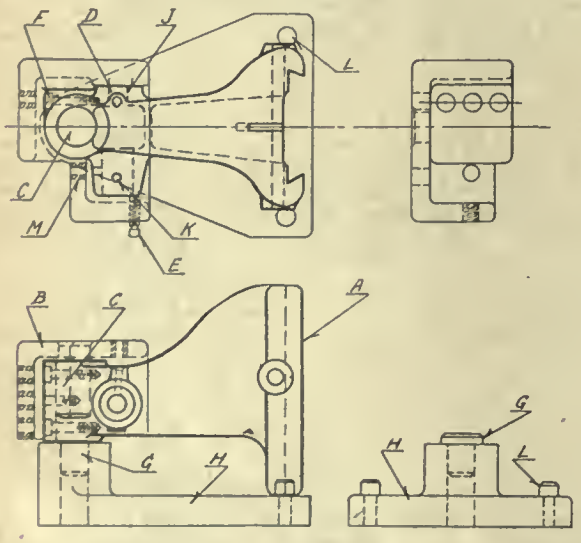

FIG. 13—DRILL JIG FOR ALL SMALL HOLES AT SPINDLE HOLE END.

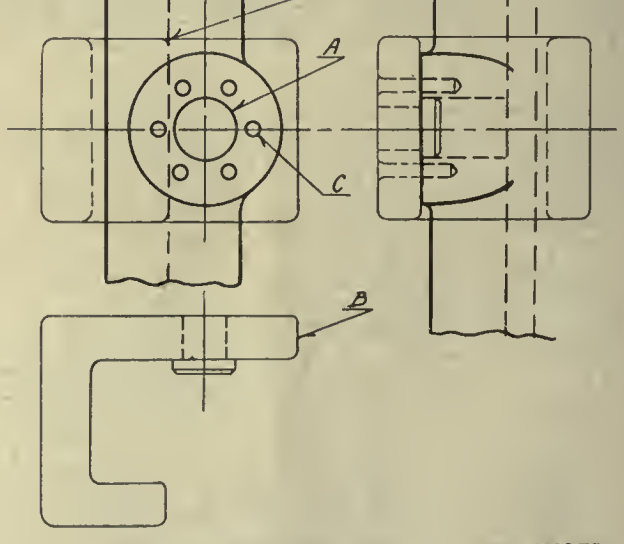

FIG. 14—DRILL JIG FOR SIX SMALL HOLES.

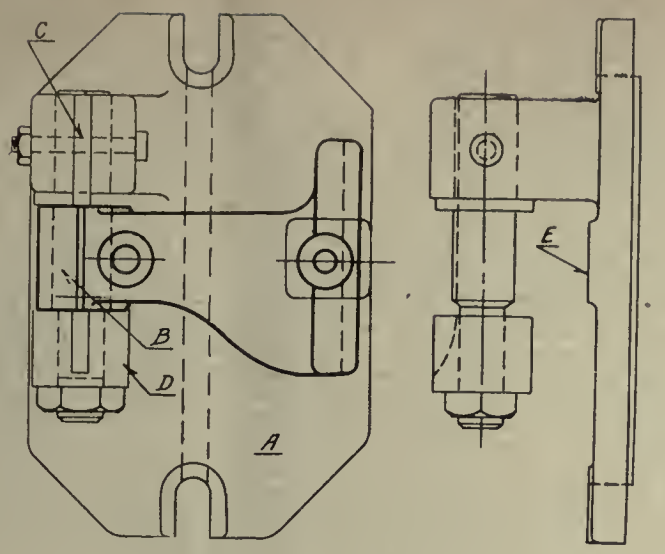

FIG. 15—FIXTURE USED FOR MILLING SLOT.

been spared which will facilitate the necessary degree of accuracy, although the tools provided are by no means elaborate, and as the production is in hundred lots it does not warrant wide expenditure.

ALCOHOL MOTOR FUEL RESEARCH

Vigorous efforts are being made by British men of science and engineers to discover all the possibilities of alcohol as a motor fuel. The increasing scarcity of petrol, and the prospects that the supplies from all visible resources will gradually shrink until they disappear in twenty-five years or so, lend a special urgency to the problem of finding a cheap and plentiful substitute. Realizing how serious the situation was, the Royal Automobile Club and the Commercial Motor Users' Association, both of Great Britain, united in paying the cost of an ambitious programme of research, at the University of Manchester, into the value of alcohol as fuel. At the request of the Alcohol Motor Fuel Committee, appointed by the British Government to survey the whole question, the programme was put in the hands of Professor Dixon, who recently gave the results of his investigations in a lecture delivered in London. A scientific study was made by Professor Dixon and his assistants of the behaviour of alcohol and of mixtures of alcohol and benzole after ignition. The main object was to find out the conditions which would give the highest efficiency with existing internal combustion engines when run on alcohol or alcohol mixtures. Information of the greatest value to designers has been collected. Investigations in this field have extended to the value of potatoes, beet, maize, and other sources of power alcohol. It is quite possible that many tropical and subtropical plants which have hitherto been regarded as a nuisance or as of little value will prove to have a high yield of the substances out of which, by fermentation, alcohol may be produced in large quantities at a low price. The research now being conducted may therefore be the means of transforming the economic prospects of more than one country.

COAL RESEARCH

The economical use of coal is a problem which concerns engineers in all parts of the world. It is especially interesting in connection with the "carbonisation" of coal at temperatures in order to obtain smokeless fuel, gas, oil and numerous valuable by-products. This problem involves a close scientific study of exactly what happens to different kinds of coal at various temperatures. Mr. Sinkinson of the Imperial College of Science, London, has hit upon a most ingenious method of discovering at what temperature coal begins to change into coke. He makes use of the fact that coke conducts electricity, while coal does not. By measuring the electrical resistance of a sample of coal as it is gradually heated he has fixed the temperatures at which various coals enter into the critical stage at which they give off their valuable products.

PEACE TYPE AEROPLANE

Most of the aeroplanes hitherto used for commercial purposes have been converted from models designed for bombing during the war. British designers have realized that better results could be obtained by designing the whole aeroplane afresh for its particular work of carrying passengers and goods. One of the first of the true Peace type of aeroplane has lately been put in service on the London to Paris and London to Amsterdam routes. This machine is able to carry eight passengers (in addition to the pilot) and up to 500 pounds of luggage. Alternatively, for goods transport only, it can carry a load of 2,240 pounds. The speed at 5,000 feet up is 121 miles per hour; calculations show that this aeroplane can convey a load almost as cheaply as the average cost of transport by road. The seats are comfortably upholstered and large windows are provided to give the passengers a good view of the country over which they are travelling.

ELECTRIC WELDING RIVET HEATING

Electric welding has already been applied in Great Britain to the building up of the cutting edge of high speed tools which have become worn or chipped. A later development of electric welding in this connection is provided by a British machine which welds a tip of hard cutting steel on to the shank of the tool. The process takes only a second or two and the weld, which is made under pressure, is the strongest part of the completed tool. This device should appeal to users of machine tools in parts of the world where facilities for repairing tools are not ample.

Another British invention which should appeal to the same class of engineer is a new electric rivet heater. Electricity has been used for this purpose before, but always by way of direct heating in an electrically-heated element. In the new machine the rivet itself forms part of the electrical resistance which generates heat. The tip of the rivet is placed on the machine, completing the circuit. In a second or two it heats up to riveting temperature, the process being so rapid that no scale forms on the metal. As many as two hundred and fifty rivets (half-inch) can be heated in an hour by this machine; and the current consumption is so low that one unit of electricity can heat about 5 pounds of rivets.

NEW ENGINEERING STANDARDS

The work of the British Engineering Standards Association is still proceeding steadily. At the request of British makers of small tools and of machine tools the Association recently undertook an inquiry into the standardization of milling cutters and reamers. After a very exhaustive study the association issued a report setting out the standards decided upon. Another interesting report from the same body deals with standard specifications for electric cooking ranges. The two sizes standardised are suitable for five persons and ten persons respectively. It may be added that when, quite recently, engineers in the United States decided to arrange for standardization on a systematic plan they adopted the model built up by the British Engineering Standards Association.

Report on Coarse and Fine Threads—Part 1

This Report Should Be of Interest to Everyone, for the Advancement Up to Date Will Reduce the Variety of Screw Threads in General Use.

IT might be well to say that the National Screw Thread Commission was created by an act of Congress in the United States on July 18, 1918, for the purpose of ascertaining and establishing standards for screw threads for use of the various branches of the Federal Government and for the use of manufacturers. The commission was to exist for a period of six months. Before the expiration of this time an extension was granted until March 21, 1920. On March 1, 1920, a further extension of two years was granted. The commission is composed of two representatives of the army, two representatives of the navy, four from engineering societies and the Director of the Bureau of Standards, Washington, D.C., who is chairman. The progress report represents the greater part of the work which it was expected would be accomplished by the commission and has been submitted for approval to the Secretaries of War, Navy and Commerce. The law provides that when the report is thus approved it is binding upon the departments in question and must be used by other Federal departments whenever possible. The following is a digest of the report so far as it concerns the fine and coarse thread series recommended.

The aim of the commission in establishing thread systems for adoption and general use was to eliminate all unnecessary sizes and in addition to utilize so far as possible present predominating sizes. While from certain standpoints it would have been desirable to make simplifications in the thread systems and to establish more thoroughly consistent standards, it is believed that any radical change at the present time would be out of place and interfere with manufacturing conditions, and would involve great economic loss.

The testimony given at the various hearings held by the commission is very consistent in favoring the maintenance of the present coarse and fine thread series, the coarse thread series being the present United States standard threads, supplemented in the series below one-quarter inch by the standard established by the American Society of Mechanical Engineers (A. S. M. E.), and the fine thread series being substantially standards that have been found necessary, consisting of sizes taken from the standards of the Society of Automotive Engineers (S. A. E.) and the fine thread series of the American Society of Mechanical Engineers (A. S. M. E.). The recommendation of these standards will tend toward their more universal use, and will constitute that important gain which is effected by standardization, with a minimum handicap.

National Coarse Thread Series

There is specified in Table I. a thread series which will be known as the National Coarse Thread Series. This series contains certain sizes known previously as the United States standard threads and also certain sizes known as the A. S. M. E. machine-screw threads. There are included in the National coarse thread series only the sizes which are essential. The National coarse threads are recommended for general use in engineering work, in machine construction where conditions are favorable to the use of bolts, screws and other threaded components where quick and easy assembly of the parts is desired, and for all work where conditions do not require the use of fine pitch thread.

National Fine Thread Series

The threads specified in Table II. will be known as the National Fine Thread Series. This series contains certain sizes known previously as the S. A. E. threads, and, also, certain sizes known as the A. S. M. E. machine-screw sizes. There are included in the National fine thread series only the sizes which are essential. The National fine threads are recommended for general use in automotive and aircraft work, for use where the design requires both strength and reduction in weight, and where special conditions require a fine thread, such as, for instance, on large sizes where sufficient force cannot be secured to set properly a screw or bolt of coarse pitch by exerting on an ordinary wrench the strength of a man.

The notation used throughout the report is shown in Fig. 1. The standard form of thread profile known previously as the U.S. standard, or Sellers profile, shall be used as shown by Fig. 2, which represents the form of thread for minimum nut and maximum screw. No allowance between nut and screw is shown in Fig. 2, this condition existing in class II., medium fit, where both the minimum nut and the maximum screw are basic.

Specifications

A clearance shall be provided at the minor diameter of the nut by removing the thread form at the crest by an amount equal to 1-6 to ¼ of the basic thread depth. A clearance at the major diameter of the nut shall be provided by decreasing the depth of the truncation triangle by an amount equal to 1-3 to 2-3 of its theoretical value.

The following general specifications will apply to all classes of fits hereinafter specified. In order to conform to the general ideas of standardization the pitch diameter of the minimum threaded hole or nut should correspond to the basic size, the errors due to workmanship being permitted above the basic size. The maximum length of engagement for screw threads manufactured in accordance with any of the classes of fit specified herein shall not exceed the quantity as determined in the following formula:

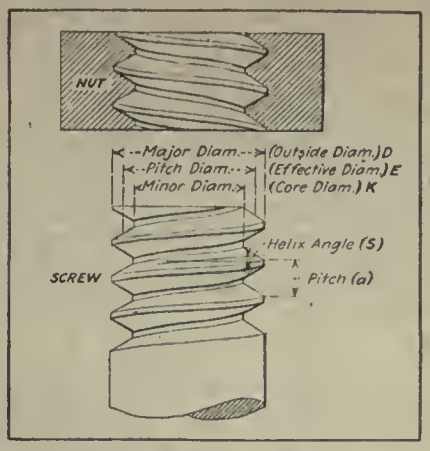
$$L = (1.5)\ D.$$

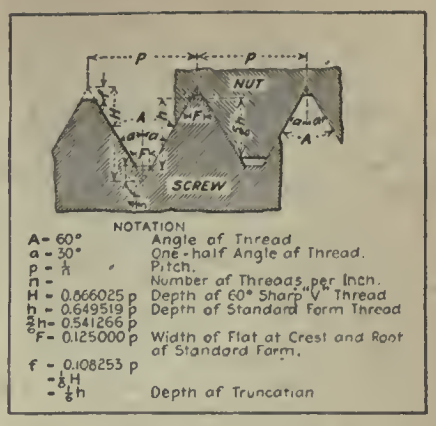
Where L = Length of Engagement;
D = Basic Major Diameter of Thread.

The specifications established for the various classes of it are applicable to the National coarse threads and the National fine threads.

Classification and Tolerances

The National coarse and fine threads shall be manufactured in accordance with the following "classification and tolerances."





P
NUT
SCREW
NOTATION
A = 60° Angle of Thread
a = 30° One-half Angle of Thread.
p = 1/n Pitch.
n = Number of Threads per Inch.
H = 0.866025 p Depth of 60° Sharp "V" Thread
h = 0.649519 p Depth of Standard Form Thread
5/8h = 0.541266 p
F = 0.125000 p Width of Flat at Crest and Root of Standard Form.
f = 0.108253 p = 1/8 H = 1/6 h Depth of Truncation

Class I., Loose Fit

The loose fit class of screw threads is intended to cover the manufacture of strictly interchangeable threaded parts where the work is produced in two or more manufacturing plants. In this class will be included threads for artillery ammunition and rough commercial work, such as stove bolts, carriage bolts, and other threaded work of a similar nature, where quick and easy assembly is necessary and a certain amount of shake or play is not objectionable.

The pitch diameter of the minimum nut of a given diameter and pitch will correspond to the basic pitch diameter as specified in the tables of thread systems given herein, which is computed from the basic major diameter of the thread to be manufactured. The dimensions of the maximum screw of a given pitch and diameter will be below the basic dimensions as specified in the tables of thread systems given herein, which are computed from the basic major diameter of the threads to be manufactured, by the amount of the allowance given in Table III. The tolerance on the nut will be plus; to be applied from the basic size to above basic size. The tolerance on the screw will be minus; to be applied from the maximum screw dimension to below the maximum screw dimension. The allowance provided between the size of the minimum nut, which is basic, and the size of the maximum screw for a screw thread of a given pitch will be as specified in Table III. The tolerance allowed on a screw

* Allowable variation in lead between any two threads not farther apart than the length of engagement

or nut of a given pitch will be as specified in Table III.

Class II., Medium Fit

The medium fit class, Subdivision A, regular, is intended to apply to interchangeable manufacture where the threaded members are to assemble nearly, or entirely, with the fingers and where a moderate amount of shake or play between the assembled threaded members is not objectionable. This class will include the great bulk of fastening screws for instruments, small arms and other ordnance material, such as gun carriages, aerial bomb dropping devices and interchangeable accessories mounted on guns; also machine screws, cap screws, and screws for sewing machines, typewriters and other work of a similar nature.

The pitch diameter of the minimum nut of a given diameter and pitch will correspond to the basic pitch diameter as specified in tables of thread systems given herein, which is computed from the basic major diameter of the thread to be manufactured. The major diameter and pitch diameter of the maximum screw of a given pitch and diameter will correspond to the basic dimensions as specified in tables of thread systems given herein, which are computed from the basic major diameter of the thread to be manufactured. The tolerance on the nut will be plus; to be applied from the basic size to above basic size. The tolerance on the screw will be minus; to be applied from the basic size to below basic size. The allowance between the size of the maximum screw and the minimum nut will be zero for all pitches and all diameters. The tolerance for a screw or nut of a given pitch will be as specified in Table IV.

The medium fit class, Subdivision B, special, is intended to apply especially to the higher grade of automobile screw thread work. It is the same in every particular as Class II-A, medium fit (regular), except that the tolerances are smaller. The tolerance for a screw or nut of a given pitch will be as specified in Table V.

Class III., Close Fit

The close fit class of screw is intended for threaded work of the finest commercial quality, where the thread has practically no back lash, and for light screw driver fits. In the manufacture of screw thread products belonging in this class it will be necessary to use precision tools, selected master gauges, and many other refinements. This quality of work should, therefore, be used only in cases where requirements of the mechanism being produced are exacting, or where special conditions require screws having a precision fit. In order to secure the fit desired, it may be necessary in some cases to select the parts when the product is being assembled.

The pitch diameter of the minimum nut of a given diameter and pitch will correspond to the basic pitch diameter as specified in tables of thread systems given herein, which is computed from the basic major diameter of the thread to be manufactured. The major diameter and pitch diameter of the maximum screw of a given diameter and pitch will be above the basic dimensions as specified in tables to thread systems given herein, which are computed from the basic major diameter of the thread to be manufactured, by the amount of the allowance (interference) specified in Table VI. The tolerance on the nut will be plus; to be applied from the basic size to above basic size. The tolerance on the screw will be minus; to be applied from the maximum screw dimensions to below the maximum screw dimensions. The allowance (interference) provided between the size of the minimum nut, which is basic, and the size of the maximum screw, which is above basic, will be as specified in Table VI. The tolerance for a screw or nut of a given pitch will be as specified in Table VI.

Class IV., Wrench Fit

The wrench fit class of screw threads is intended to cover the manufacture of threaded parts ¼-inch in diameter or larger which are to be set or assembled permanently with a wrench. Inasmuch as for wrench fits the material is an important factor in determining the fit between the threaded members there are provided herein two subdivisions for this class of work, namely, subdivision "A" and subdivision "B." These two subdivisions differ mainly in the amount of the allowance (interference) values provided for different pitches.

Subdivision "A" of Class IV., wrench fit, provides for the production of interchangeable wrench fit screws or studs used in light sections with moderate

* Allowable variation in lead between any two threads not farther apart than the length of engagement.

stresses, such as for aircraft and automobile engine work.

Subdivision "B" of Class IV., wrench fit, provides for the production of interchangeable wrench fit screws or studs used in heavy sections with heavy stresses, such as for steam engine and heavy hydraulic work.

The pitch diameter of the minimum nut of a given diameter and pitch for threads belonging to either subdivision "A" or subdivision "B," will correspond to the basic pitch diameter as specified in tables of thread systems given herein, which is computed from the basic major diameter of the thread to be manufactured. The major diameter and pitch diameter of the maximum screw of a given diameter and pitch for threads belonging in either subdivision "A" or subdivision "B" will be above the basic dimensions as specified in tables of thread systems given herein, which are computed from the basic major diameter of the thread to be manufactured, by the amount of the allowance (interference) provided. The tolerance on the nut will be plus; to be applied from the basic size to above basic size. The tolerance on the screw will be minus, to be applied from the maximum screw dimensions to below maximum screw dimensions. At the present time the commission does not have sufficient information or data to include in its tentative report values for tolerances and allowances for wrench fits. It is hoped, however, that sufficient information resulting from investigation and research will enable the commission to decide at an early date the allowance and tolerance values for the two classes of wrench fits included herein, which will be applicable to the various materials, and which will meet the requirements found in manufacture of machines or product requiring wrench fits.

Tolerances

There are specified herein for use in connection with the various fits established, three different sets of tolerances, as given in Tables III, IV, V and VI.

The tolerances as hereinafter specified represent the extreme variations allowed on the work.

The tolerance limits established represent, in reality, the sizes of the "Go" and "Not Go" master gauges. Errors in lead and angle which occur on the threaded work can be offset by a suitable alteration of the pitch diameter of the work. If the "Go" gauge passes the threaded work interchangeability is secured and the thread profile may differ from that of the "Go" gauge in either pitch diameter, lead or angle. The "Not Go" gauge checks pitch diameter only, and thus insures that the pitch diameter is such that the fit will not be too loose.

The tolerances established for Class I, loose fit, and Class II, medium fit, permit the use of commercial taps now obtainable from various manufacturers. For Class III, close fit, in which it is desired to produce a hole close to the basic size, it is recommended that a selected tap be used.

The pitch diameter tolerances provided for a screw of a given class of fit will be the same as the pitch diameter tolerances provided for a nut corresponding to the same class of fit. The allowable tolerances on the major diameter of screws of a given classification will be twice the tolerance values allowed on the pitch diameters of screws of the same class.

The minimum minor diameter of a screw of a given pitch will be such as to result in a basic flat (⅛ x p) at the root when the pitch diameter of the screw is at its minimum value. Note: When the maximum screw is basic the minimum minor diameter of the screw will be below the basic minor diameter by the amount of the specified pitch diameter tolerance.)

The maximum minor diameter may be such as results from the use of a worn or rounded threading tool when the pitch diameter is at its maximum value. In no case, however, should the form of the screw as results from tool wear be such as to cause the screw to be rejected on the maximum minor diameter by a "Go" ringe gauge the minor diameter of which is equal to the minimum minor diameter of the nut.

The maximum major diameter of the nut of a given pitch will be such as to result in a flat 1-3 of the basic flat (1-24 x p) when the pitch diameter of the nut is at its maximum value. (Note: When the minimum nut is basic the maximum major diameter will be above the basic major diameter by the amount of specified pitch diameter tolerance plus 2-9 of the basic thread depth.) The nominal minimum major diameter of a nut will be above the basic major diameter by an amount equal to 1-9 of the basic thread depth plus the neutral space. This results in a clearance which is provided to facilitate manufacture by permitting a slight rounding or wear at the crest of the tap.

In no case, however, should the minimum major diameter of the nut as results from a worn tap or cutting tool be such as to cause the nut to be rejected on the minimum major diameter by a "Go"' plug gauge made to the standard form at the crest.

The tolerances on minor diameter of a nut of a given pitch will be 1-6 of the basic thread depth, regardless of the class of fit being produced. In Fig. 3 there are shown the various relations previously specified for tolerances on both the screw and the nut.

The specifications establishing the various sets of tolerances for the different classes of fit specified herein will apply to the manufacture of national coarse threads, national fine threads, and wherever applicable to the production of all special threads.

Where tolerances are desired for a special thread and the pitch is not listed in the tables given, the tolerance values should be chosen corresponding to the number of threads per inch nearest to that of the special thread being

FIG. 3—Relation between pitch diameter tolerances and tolerances on major and minor diameters. (Drawing shows one side of thread only and therefore spaces indicate half tolerances or tolerances on radii.)

For instance, the tolerance on a screw having 11½ threads per inch would correspond to the tolerances specified for a screw of 11 threads per inch.

With reference to the classification of screw thread fits attention is called to the fact that the minimum threaded hole or nut corresponds to the basic size; that is, the pitch diameter of the minimum nut is basic for all classes of fit. This condition permits the use of taps, which, when new, are oversize, and which are discarded when the whole cut is at the basic size. In order to secure the desired fit the screw size is varied; the maximum screw corresponds to the basic size for the medium fit class, is slightly above basic size for close fit class, considerably above the basic size in the wrench fit class, and below the basic size for the loose fit class.

The tolerances specified in column 7 of Tables III, IV, V and VI are the net tolerances, which are in no way reduced by permissible manufacturing tolerances provided for master gauges. These master gauge tolerances are provided for by being added to the net tolerances. Thus the extreme or drawing tolerances are the net working tolerances increased by the master gauge increment or equivalent diametrical space required to provide for the master gauge tolerances. The limits established for the extreme tolerances should in no case be exceeded. The application of gauge tolerances in relation to tolerances allowed on the work can be best understood by considering that the extreme tolerances represent the absolute limits over which variations of the work must not pass. The manufacturing tolerances required for master gauges are then deducted from the extreme working tolerances, producing the figures specified as net tolerances. Further reduction of the extreme tolerances is caused by the manufacturing tolerances required for the inspection gauges and working gauges.

It is essential that the proportion of the tolerance used by the workmen producing the work at the machine be well within the net tolerance limits. The net tolerance limits as established by the master gauges may be considered as the largest circle of the target, the space representing the width of the line establishing the largest circle. The marksman always aims to hit the bull's-eye. Any mark inside of the largest circle or occupied by the master gauge tolerances cutting the circle scores. Any mark outside of the largest circle does not score. The same is true in producing work—the careful manufacturer will aim to produce work which is in the centre of tolerance limits. The bull's-eye in this case, which is the working tolerance used at the machine, will be considerably less than the net tolerance and the result will be that a very large percentage of the work will be accepted, and spoiled or rejected work will be reduced to practically nothing. If the net tolerance limits are used as working limits at the machine there will be a larger percentage of rejections due to differences in gauges and wear of both tools and gauges. The application of this principle is illustrated in Fig. 4, which is a diagram showing the relative position of master gauge, inspection gauge and working gauge tolerances with reference to the net tolerance allowed on the work.

Extreme Limits

The extreme limits as shown by the lines at *A* and *a* in Fig. 4 represent the absolute limits within which all variations of the work must be kept, including permissible variations provided for manufacturing tolerances on master gauges. The manufacturer of the product should not be concerned with the extreme tolerances but should work within the net tolerance limits. The extreme tolerance limits are included for the manufacturer or inspector of master gauges, and in no case should master gauges be approved which are outside of the dimensions established by these extreme limits.

The lines at *b* and *B* represent the net working tolerance limits within which all manufactured product must come.

The regions *AB* and *ab* represent the space required to provide for the "Go" and "Not go" master gauge tolerances respectively.

Master gauges provide physical stand-

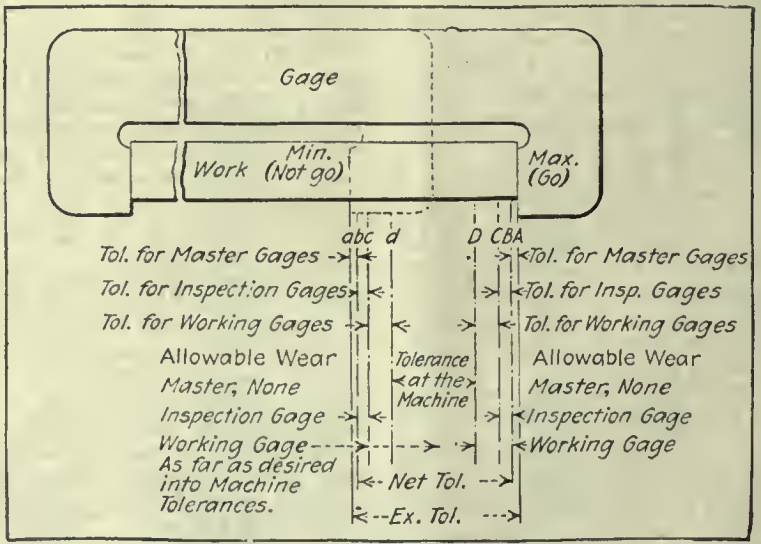

FIG. 4—Relation of gage sizes, tolerances and wear limits with reference to gaging an external part. (For gaging an internal part tolerances and wear are provided for in a similar manner.)

ards representing the limits placed on the work. The master gauge tolerances are placed within the extreme tolerance limits. However, the manufacturer re-

ceives the full benefit of the specified net tolerance. So far as the manufacturer is concerned he should in no case permit variations in the work produced to extend beyond the limits established by his master gauges.

The regions *BC* and *bc* represent the space required to provide for the "Go" and "Not go" inspection gauge tolerances respectively. The inspection gauge tolerances are placed inside the net tolerance limits.

The regions *DC* and *dc* represent the space required to provide for the "Go" and "Not Go" working gauge tolerances respectively. These working gauge tolerances are placed within the net tolerance limits. This insures that any work accepted by the working gauge will be accepted by the inspection gauge, and that work accepted by both working gauge and inspection gauge will be within the net tolerance limits.

The "Go" master gauge is not to be used on the product. It serves as a standard for comparative measurements or as a check for verifying the inspection or working gauge. It also serves as a standard representing the wear limit for the inspection or working gauge. The "Go" master gauge is, therefore, not subject to wear.

The "Go" inspection gauge may wear until it reaches the size represented by the master gauge. As shown in Fig. 4 the wear provided for the inspection gauge is that which takes place within its own tolerance region. However, a definite allowance for wear may be provided for the "Go" inspection gauge in addition to its tolerance region if desired.

The "Go" working gauge wears within its own tolerance limits and through the inspection gauge tolerance region, and continues to properly accept work until worn to the dimension established by the "Go" master gauge. It is good practice to transfer the "Go" working gauge to use as an inspection gauge when it is worn so that its dimension corresponds to that of the inspection gauge.

The "Not go" master gauge is not to be used on the product. It serves as a standard for comparative measurements or as a check to verify the inspection or working gauge. It is, therefore, not subject to wear.

The "Not go" inspection gauge wears within its own tolerance region and into the tolerance region established for the "Not go" working gauge. It is good practice to transfer the "Not go" inspection gauge to use as a working gauge when it is worn so that its dimension corresponds to that of the "Not go" working gauge.

The "Not go" working gauge wears within its own tolerance region into the working tolerance. It is purely an economic question as to when the "Not go" working gauge should be discarded, due to wear, inasmuch as continued use reduces the working tolerance, the result of which must be balanced against the cost of a new gauge.

(To be continued)

MOTOR INDUSTRY TAXED TO THE LIMIT, FINDS GOING HARD

SPEAKING to a newspaper reporter in Oshawa a few days ago, the manager of General Motors of Canada, Ltd., expressed the hope that conditions would improve, but admitted that business at present was well below normal. The present slackness in the motor industry has been caused by many conditions. The chief reason for the dull conditions lies in the fact that the motor industry has been hard hit by the imposition of heavy excise taxes. Under the old taxation prior to May 1, which the automobile industry and accessory trades considered very high, the General Motors of Canada, Ltd., have paid to the Dominion Government approximately $2,500,000 in special taxes. Since May 1 these taxes have been very much increased, and in the case of the highest priced McLaughlin cars have been doubled. It is the impression of the General Motors executive that the motor industry is unduly taxed. Taxes are now so high that prices must be correspondingly increased, which has caused demand to slow up.

Tax of $780 on One Car

On the lowest priced automobile made by the McLaughlin Motor Car Co., the tax amounts to $238 per car. The highest priced car is taxed $780. The special taxes are levied when the car is sold to the dealer and do not include customs duty and business profits' taxes. It has been the contention among many car manufacturers that they are being taxed out of proportion to other staple industries. The tax is 240 per cent. over and above that imposed by the United States Government upon the American buyers of cars.

General unsettled trade conditions and adverse rate of exchange, together with unsatisfactory conditions in Europe, where money is scarce and borrowing power at its lowest ebb, and the heavy excise and other taxes imposed by the Government, have for some time past had their effect on the operations of the General Motors of Canada, Ltd., in Oshawa, with the result that it has been expedient to decrease production for the time being.

No Easy Task

"Nobody knew what would happen as things were so uncertain." The company was doing its utmost to improve its export trade, but with the buying powers of Europe greatly curtailed as a result of the war and its after effects, and with the present adverse rate of exchange, the task was no easy one.

With business in the unsettled condition it is at present, it has been found necessary to decrease the staffs in many of the departments of the General Motors of Canada, Ltd. Where men have to be temporarily laid off, care is being taken to discriminate between men who have families to support and those who are single. Men who own their own homes and live in Oshawa permanently are also given consideration. It might be necessary to resort to half time in order to keep as many men employed as possible until conditions have righted themselves.

IMPROVEMENT IN ROAD MAKING

The spraying of roads with tar has now become almost a standard means of rendering them waterproof and free from dust, but the process has certain difficulties attached to it. One is the difficulty of keeping traffic, both vehicular and pedestrian, off the road until the tar has been covered by chippings. Several ways have been devised of carrying out both operations at the same time, and perhaps the most effective is that recently adopted by a British road engineer. He uses a 5-ton tractor to haul a 320-gallon tar tank followed by a 5-ton tipping waggon filled with chippings. At the back of the wagon is a V-shaped trough through which the chippings fall upon the freshly tarred surface. To prevent the choking of this trough it is traversed by a shaft with projecting spikes, and this shaft is rotated by a chain geared to the rear axle of the wagon. This simple equipment is a great labour saver and it spreads the chippings much more evenly than can be done by hand.

SELLING GAS SCIENTIFICALLY

British gas undertakings are leading the way in the sale of gas on a scientific basis. Henceforward, instead of selling gas at so much per thousand cubic feet, they will sell it according to its heating value. A new unit, christened the "therm," will be used for this purpose. A therm is equivalent to one hundred thousand British Thermal units. Consumers will now pay something like eleven pence per therm. The pressure of the gas will be carefully regulated under penalties.

The discovery of a new alloy, with important industrial possibilities, is announced by the Academy of Sciences, Paris. It is to be called Elinvar, an alloy which is extensively used by makers of scientific instruments in France. The new alloy, it is claimed, is an improvement on Invar, and is peculiarly valuable by reason of its uniform elasticity.

The erection of the Deep Creek viaduct on the Pacific and Great Eastern Railway of British Columbia has been commenced, and is noteworthy, as the structure will be one of the highest of its type in America. The base of the rail will be over 300 feet above the pedestals.

A Course of Instruction for the Graded Certificate

We Will in This Course Go Through the Mathematical and Theoretical Work to Cover Every Grade of Certificate Issued by the Ontario Board

By T. H. FENNER

WE considered in the last article the various forms of lap joints, and now come in logical sequence to the butt strap type. These are double riveted, triple riveted, and quadruple riveted, the triple riveted being most in use. They are called butt strap joints because the edges of the plates to be joined are butted together and are secured by straps or plates of metal, which cover the joint, inside and outside, and are riveted through straps and plate to make a solid joint. This type of joint makes for a high percentage of strength, and at the same time preserves the truly cylindrical shape of the boiler. The rivets, being in both double and single shear, thereby gain in strength. A rivet is said to be in double shear when it holds together three plates, and therefore before it can be sheared has to be cut through in two places instead of one. The shearing strength of such a rivet is usually allowed to be 1¾ times the shearing strength of a rivet in single shear.

In the double riveted double strap butt joints the straps are usually made equal in width on the inside and outside of the joint and the full number of rivets is used in each row. In the treble riveted double strap butt joint the outside strap is only made wide enough to take in the two inside rows, and every alternate rivet is left out of the outside row. In the quadruple riveted double strap butt joint the straps are also unequal, and besides every alternate rivet being left out of the third row, two rivets are left out of the outside row. In some cases the strap is cut away on the outside edge to conform to the rivet line of the third row, thus securing a better caulking edge. This is not universal practice, but is a feature of some well-designed joints. The writer knows of at least one joint of this type with an efficiency of 92½ per cent.

When designing a joint of the butt strap variety, the same procedure is gone through as in the others. We have also to consider the thickness of the straps, and the Ontario regulations give a definite rule for determining this dimension. The thickness of straps where the full number of rivets in each row is used and double straps is found from the formula

$$T_1 = \frac{5}{8} T$$

where T_1 is the thickness of strap and T thickness of shell plate. For double straps when straps are unequal in width and every alternate rivet omitted in outer row

$$T = \frac{5T \times (P - d)}{8 \times (P - 2d)}$$

Suppose we consider first a double strap double riveted joint, with equal straps and full number of rivets in each row. In a joint of this kind all rivets are in double shear, and therefore we must reckon for the number of rivets in a pitch $2 \times 1.75 = 3\frac{1}{2}$. This will of course have the effect of increasing the rivet strength, and in order to equalize it we must increase the pitch, which brings up the plate strength.

Suppose we wish for a plate strength of about 80 per cent., let us see what results we can obtain. We have $\frac{p - d}{p} \times 100 = 80$, and if we assume a ⅜-inch plate and ¾-inch diameter rivet we get

$$\frac{p - d}{p} \times 100 = 80$$

$$p - d = .8p$$

$$d = .p - .8p = .2p$$

Then if d = .75, the pitch will be

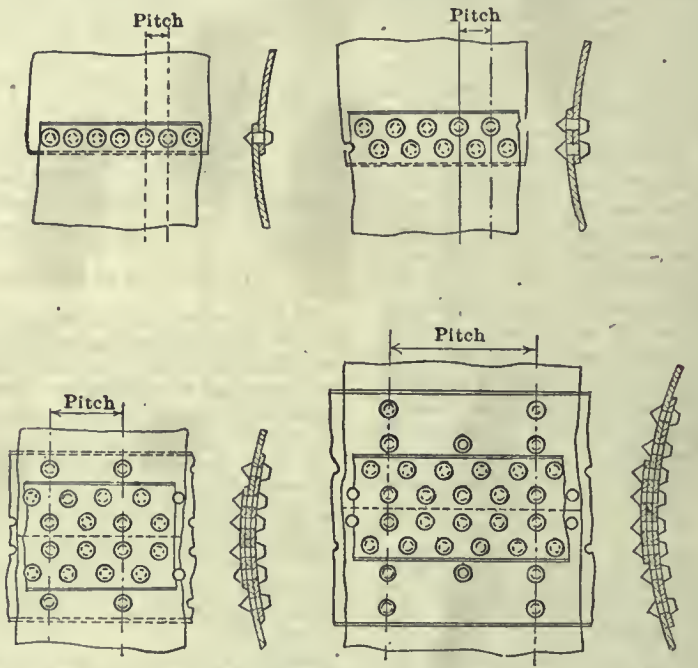
$$\frac{.75}{.2} = 3.75$$

With a pitch of 3.75 inches, diameter .75, and plate strength efficiency of 80 per cent., what will be the rivet strength efficiency? Let us work it out, taking C as .7:

$$\frac{a \times n \times c}{p \times t} = \%$$

$$\frac{3 \times 3 \times .7854 \times 7 \times 4 \times 8 \times 70}{4 \times 4 \times 2 \times 15 \times 3 \times 100} = 76.9$$

say 77 per cent. which is within 3 per cent. of the plate strength, and may be taken as a pretty evenly balanced joint. We could increase the strength of the rivet section by decreasing the pitch, but this would also decrease the plate strength, and as we have allowed a low constant for the rivets, we may feel safe in leaving it as it is.



THE LOWER FIGURES ILLUSTRATE A TRIPLE RIVETED DOUBLE STRAP BUTT JOINT, AND A QUADRUPLE RIVETED DOUBLE STRAP BUTT JOINT, BOTH WITH UNEQUAL STRAPS.

We must now consider the joint from the point of view of possible failure, or as we say, analyse it. In a butt joint the rivets on one side of the centre line only are considered, as conditions on each side of the centre line are exactly the same. Taking the plate from the centre line it may crush in front of a rivet in the inner row and shear one rivet in double shear in the outer row. It may shear two rivets in double shear, or it may tear between the rivets of the inner row and shear one rivet in the outer row. It may tear between the rivets on the outer row, and this is usually the weakest point.

Suppose it crushes in front of one rivet and shears one rivet. We have

$$d \times t \times 90{,}000 + a \times 1.75 \times 42{,}000$$

$$\frac{3}{4} \times \frac{3}{8} \times 90{,}000 \times \frac{3}{4} \times \frac{3}{4} \times .7854 \times 7/4 \times 42{,}000 = 57{,}726$$

The unit section is $3.75 \times .375 \times 60{,}000 = 84{,}000$ lbs. Therefore the percentage in this case is $\frac{57{,}726}{84{,}000} = 68.7$ per cent. which is lower than either percentage already obtained. If we look into this a moment we will see why. Comparing

this joint with the double riveted lap we see that although we have the advantage of the rivets being in double shear, for this particular case of crushing the plate and shearing one rivet, the greater pitch of the butt joint offsets this advantage. It is obvious that to bring this part of the joint up to a closer strength proportion, we must increase the rivet area. This will decrease the percentage of plate strength, but we shall have to make a compromise. By making the rivets 13-16 dia. instead of ¾ in. we shall get a closer relation.

$$\text{First } \frac{3.75-.8125}{3.75} \times 100 = 78.3\% \text{ plate strength,}$$

$$\text{and } \frac{13\text{x}13\text{x}.7854\text{x}7\text{x}4\text{x}8\text{x}70}{16\text{x}16\text{x}2\text{x}15\text{x}3\text{x}100} = 90.3 \text{ rivet strength.}$$

Now to consider again crushing in front of one rivet and shearing one rivet in double shear.

13/16 x ⅞ x 90,000 + 13/16 x 13/16x.7854 x 1.75 x 42,000
= 27,414 + 38,106
= 65,520 lbs.

As the unit section is 84,000 lbs. we get

$$\frac{65,520}{84,000} \times 100 = 78\%$$

In the case of shearing two rivets we will have

13/16 x 13/16 x .7854 x 1.75 x 2x42,000 = 76,212 lbs., which gives a percentage of 90.

For tearing between one row and shearing one rivet we have

(p—d)t x 60,000 + a x 1.75 x 42,000
66,090 + 38,106

which gives over 100 per cent.

Tearing between the rivets of the outer row gives (p—d)t x 60,000 = 66,090, and this, of course, gives 78 per cent.

We have therefore a joint not very much higher in strength than a good lap joint, and considerably more expensive to manufacture. This is the reason that comparatively few of these joints are met with.

The Triple Riveted Butt Joint

Coming to the triple riveted butt strap joint, we have reached probably the most widely used joint in high class boiler manufacture. The efficiency of this joint is high, usually running about 86 per cent. It is not unusual to find the rivet strength in these joints considerably higher than the plate strength, and this is accounted for by the large number of rivets in double shear. The weakest part of the joint is the plate section at the outside row of rivets, and if this is high enough the rest will be pretty near right. The high efficiency is due to the large pitch in the outer row of rivets where each alternate rivet is omitted. In a joint of this type there are five rivets in a pitch, and of these four are in double shear, thus making 4 × 1.75 + 1 = 8 rivets practically, when considering rivet strength. The methods of considering the joint are exactly the same, except that the analysis is more complicated. After the dimensions are determined on, we must also check up and see that the diagonal pitch does not exceed the limit set by the Ontario regulations. We will take for purpose of example a double strap triple riveted butt joint, with unequal straps, and every alternate rivet omitted from the outer row, and an efficiency of say 86 per cent. The plate thickness is 7-16 inches.

The first step is to obtain the pitch for the outer row of rivets. With 7-16 inch thickness of plate, we can assume a 15-16 inch rivet. Then we have

$$\frac{p-d}{p} \times 100 = 86$$

$$p-d = .86p$$

$$d = .14p$$

And if $d = .9375$ then $p = \frac{.9375}{.14}$ which gives 6.69, or nearly 6¾. We can take this pitch as a basis to work on.

For rivet strength we shall have then

$$\frac{.69 \text{ x } 8 \text{ x } 4 \text{ x } 16 \text{ x } 70}{27 \text{ x } 7 \text{ x } 100} \times 100 = 130\%$$

Which is ample, being stronger than the solid section.

In how many ways can this joint fail? As in the last case, take from the edge of the plate and work outwards. The first case in which failure may occur is by crushing the plate in front of the rivets in the inner row, and shearing two rivets in double shear, and one rivet in single shear.

The unit section is

p t 60,000 = 6.75 x .4375 x 60.000 = 177.000
15/16 x 7/16 x 2x90,000 + .69x4.5x42,000
= 204,210

This is sufficiently high to allow it to be neglected.

In the next case the plate may tear between the rivets of the inner row, and shear two rivets in double shear, and one in single shear. This would be

(p—2d)t x 60,000 + ax1.75x2 + a x 42,000
= (6.75—1.875) x .4375 x 60,000 + .69 x 4.5 x 42,000
= 258,378

which is also above the unit strength. The joint may fail in the third instance by tearing at the second line of rivets and shearing one rivet in single shear. (p—2d) t x 60,000 + a x 42,000 = 156,948 and the percentage to unit strength is 88.6, which is higher than the plate strength at outer row.

If the joint fails through shearing all the rivets it will have to shear four rivets in double shear and one in single shear.

4a x 1.75 + a x 42,000 = 231,840

which is much higher than the unit strength. The last case to consider is tearing at the outer row, which is

(p—d)t x 60,000 = 15,258

and the percentage is 86.2, which may be considered the efficiency of the joint.

The minimum diagonal pitch is found for the inner and middle row from the formula, Diag. pitch $= \frac{3P+4d}{10}$

and for the outer and middle row $= \frac{3}{10} P + d$.

The minimum distance between middle and outer rows is obtained from the formula

$$\sqrt{\left\{\frac{11}{20} P + d\right\}\left\{\frac{1}{20} P + d\right\}}$$

and for the inner and middle rows from

$$\sqrt{\frac{(11\,P + 8d)\ (P + 8d)}{20}}$$

We will not enter into the solution of these formulae immediately, but will use them when designing the actual joint for the boiler we are considering.

The Quadruple Riveted Joint

This is a further development of the butt joint, and is used where a very high joint efficiency is required. The rivet section in this joint is very large, there being eight rivets in double shear, and three in single shear, giving a total of 17 rivet areas in the joint. The outside strap covers only the two inside rows of rivets, and the third row of rivets leaves out every alternate rivet, and the outer row has twice the pitch of the third row. The efficiency of the joint will depend on the efficiency at the outer row, which will be as usual P—d. This pitch must never exceed 10 inches in any case. With a 90 per cent. joint the pitch of the outside row would be 9⅜ inches, that of the next row 4 3-16, and the inside row 2 3-32 inches. The joint may fail by crushing the plate in front of four rivets in double shear and three in single shear. It may tear between the rivets of the inside row, and shear four rivets in double, and three in single shear. It may tear across the second row of rivets and shear three rivets. It may tear at the third row and shear one rivet, or it may tear at the outer row. Shearing all rivets is hardly likely. The reason for fixing a minimum diagonal pitch is to preclude failure by tearing across a diagonal pitch line. The least value of the joint is the plate percentage at the outside row, and this, as we know, is 90 per cent.

MONEY FROM "WASTE" COAL

Close to the pit-head of many coal mines there lie huge "tips" of small coal. When coal of good quality was cheap, these tips were looked upon as waste because the heating value of the stuff was so small that no one would pay enough to cover the carriage. The huge increase in the cost of coal has, however, turned attention to the economic possibilities of these heaps of low-grade fuel. A large company has been formed to acquire the heaps and to transform the coal dust into briquettes of a form and composition suitable for domestic and industrial purposes.

John Conley is No Longer a Drill Press Operator

The Shaper Now Receives His Attention, and Incidentally He Learns a Few Pointers About the Action of the Stroke of This Machine.—He Also Tells of an Interesting Jig.

By J. DAVIES

READERS will no doubt be glad to hear that John has been promoted. He is no longer a lowly drill press hand, but answers to the name of shaper operator. The foreman, who in spite of his seeming brusqueness has John's interest at heart, is giving him some advice and as we creep up behind him, so to speak, let us hear what he has to say.

"Now, John," he commences, "don't be afraid to ask questions. If you have any doubt about how to tackle a job ask how it was done before. Many a time you will have to exercise your own ingenuity and improvise methods of your own.

"You know it is not the method that counts so much as the result, but they must both be taken into consideration. In some cases the end does not justify the means. For instance, a shell mechanic came in the other day and was given a job on a large drill press. He put the job on the table and got a drill from the stock room which happened to be a long one and would not go over the job without lowering the table. He evidently did not know that the table could be lowered, so he took the drill to the blacksmith and asked him to cut 2 inches off it. That was a method we didn't quite approve of so we asked him to kindly introduce that idea into some other shop.

"The shaper, or the fitter's friend, as it has sometimes been called, and the planer are so nearly akin that most of the methods and principles are applicable to both. Much of the same work can be done on either shaper or planer, the same methods of securing the work and the same kind of tools being used, but the shaper is best adapted for light work and short cuts, or where a cut of a definite length is required. For example, cutting a key seat in the end of a shaft, or cutting up to a square shoulder. Most shaper work is held in a vise bolted to the table, the vise being usually graduated so that it can be set to any angle.

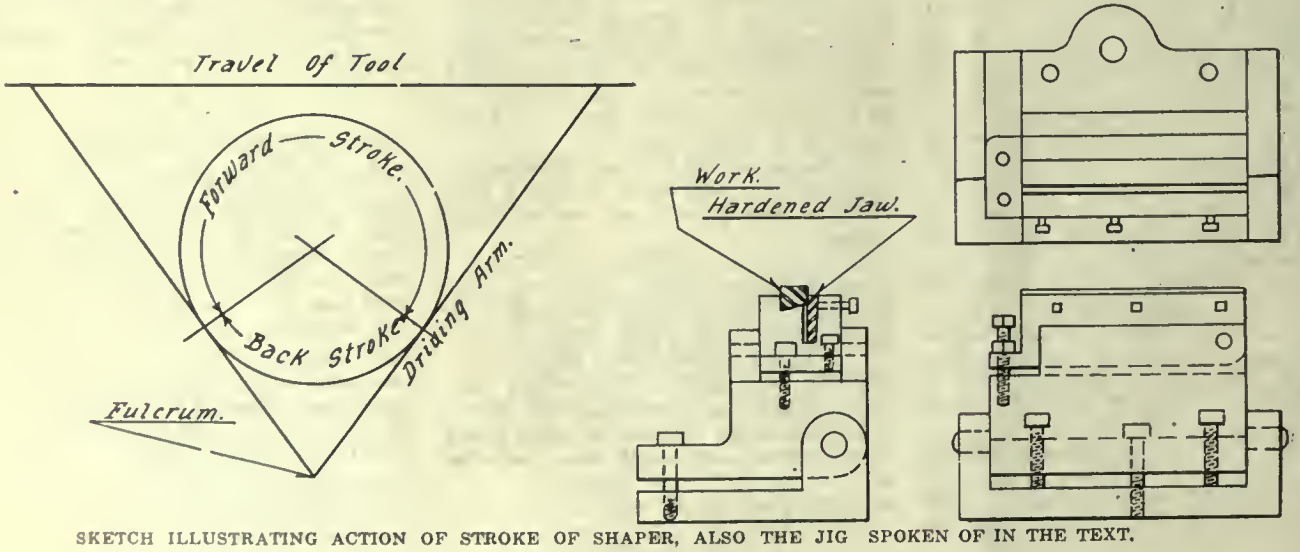
"The first consideration in planer or shaper work is to decide if the work can be finished in one setting. Never move or reset a job if it can be avoided. Now here is a blanking die with a hexagon hole through it. I want it shaped so as to leave a margin of steel around it about ½ inch wide. This is to reduce the work of subsequent grindings and it can be done at one setting by swinging the vise around to suit the different angles. Be sure not to move the tool up or down when taking the finishing cut."

With a little friendly advice from his neighbor John got along with this job fairly good until the overhead belt came off. He secured the belt stick to put it on again, but unfortunately got on the wrong side of the pulley. John was conscious that several of the men were looking on smiling, so determined to show them that he could do the job correctly. He struggled, pushed and got red in the face, but finally jammed the belt stick between the shaft and the pulley, breaking the belt. This necessitated a trip to the belt repair man, who on repairing the belt put it on for John, who was watching intently to see how it was accomplished. John learnt something on seeing him go to the other side of the pulley, give the belt one little flip, and it was on.

A little later the foreman came down the shop with a short piece of round stock in his hand. Stopping opposite the shaping machine, "John," he said, "I see you have just about finished that job. Here is a short piece of round stock. I want you to shape a square on the end of it to suit a wrench. Make it about 1 in. long and as big as the stock will allow."

John carefully measured the size of the bar and found it was just one inch. He had found out at the evening school that a square drawn inside a circle was .7071 times the diameter of the circle, so he reasoned to himself that if the finished size was .7071, and it was an inch to begin with, he would have to take off .293 or .1465 from each side. As the piece was short he stood it up on end in the vise, using a pair of vee blocks to hold it straight. He cut .146 from one side, then cut the other side until it measured .707. He was just about to loosen up the vise, turn the piece around to do the other two sides, when he remembered how he had finished the last job by moving the vise around, and setting it by the graduations marked on the base. He moved the vise 90 degrees, repeated the operation and completed a very creditable job which he was proud to show to the foreman. He was rather disappointed when the foreman said:

"The job is all right, but it took you four times longer than it should. I told you it was a square for the end of a wrench, so you didn't need to monkey around with micrometers measuring half thousandths, also it wasn't necessary to cut so much wind at the end of each stroke. You could have shortened the stroke and speeded up the machine.



SKETCH ILLUSTRATING ACTION OF STROKE OF SHAPER, ALSO THE JIG SPOKEN OF IN THE TEXT.

The amount of time required depends upon the degree of accuracy, and the degree of accuracy depends upon the job. I suppose I should have told you it didn't matter to a thirty-second. That old saw about making everything as perfect as you can is all nonsense. The requirements of every job must be considered separately and your own common sense will tell you the nature of the finish that the work calls for."

When John reached home that evening his father noticed that he had a liberal supply of cotton bandage on his hand.

"Hello, John, what is the matter with your hand?" "I was shifting the belt from one speed to another while it was running pretty fast, and there was a piece of wire sticking out where the joint was and it made a nasty gash in my hand. I'll bet you I don't get caught that way again.

"By the way, father, I had quite an argument in the shop today about the return stroke of the shaper. I agreed that the length of the stroke makes no difference in the time required for each stroke, but I can't see how the return stroke is faster than the forward one as my friend claimed it was. Here is my argument. The slide that carries the tool is driven by a disc that has a slot in it, and the length of stroke is governed by the position of the driving pin in the slot. Now that disc is revolving at a uniform speed, one half a revolution drives the slide forward, and the other half drives it back. Since each half would require the same time, the backward and forward motion must take the same time. What do you think about it, father?"

"Your conclusion would be correct, John, if your statement were true, but unfortunately for your argument your statement is not true. The forward stroke takes more than half a revolution and the backward stroke less, according to the length of the rocker arm. Here is a sketch that shows it very clearly. You will notice that the shorter the rocker arm, the faster the back stroke, also that the stroke is not uniform, being fastest at the middle and slowest at the ends.

(*See sketch on previous page*)

"I see how it works. I shall have to take it all back what I said."

"I am glad you investigate things for yourself and know for sure the how and the why. It is surprising what a lot of erroneous ideas pass muster even with good mechanics. Well, is there anything I can help you with before we go to bed?"

"Yes, there is one other job, but it seems so simple I am ashamed to ask the boss to show me how to do it."

"Don't be afraid to ask for information. That's what the boss is there for and I know he would be glad to show you anything on any job and get you started right. What is the job?"

"To shape two blocks of steel for bolt dies perfectly square, and to a given length. The limit of error allowed being .005."

"What seems to be the trouble?"

"Well they are just cut off the rough stock, and after shaping one side, I can't get them to lie flat on the bottom of the vise no matter how I try to hammer them down. When I tighten up the vise they seem to raise up on one side or the other, the result being they are not square."

"I think I can give you an idea that will help you. In the first place, see that the sides of the fixed jaw are perfectly square. Then take your block and machine one side. Now place the side you have just machined against the solid jaw of your vise, and take a piece of angle iron for a packing piece and place between the work and the other jaw in such a manner that the pressure will be on 3 points. This will cause the side you have just finished to bear all over the fixed jaw and will be perfectly square with a cut taken off the top.

"Test the work as you go along and if you should find you want, say, .005 in. more off one end than the other, let your tool just touch the high spot and make a .005 feeler pass between your work and the tool at the low end. Setting a job with a tool is more accurate than with a lever or surface gauge, or in fact any other tool."

"Why so, father? Suppose I got an indicator and set the job .005 higher one end than the other, wouldn't that be just as good and save me putting the machine backwards and forwards?"

"It might, and it might not, but if you want a really accurate job I wouldn't trust it, because your shaper table may not be in the same plane as your tool and your indicator wouldn't show it. You could put your indicator in the tool post and any error in the machine would then automatically correct itself."

"I see," said John, "I used a jig today, father, to shape up some dovetail taper keys. These keys were to hold some inserted forming tools in a holder and were to be shaped to a given angle on the side, and ⅛ inch taper to the foot lengthways. They were to be all alike, or interchangeable, as the boss said. I thought I would have an awful job holding them, but that little jig did the trick all right."

"Is that so —what was the jig like and how did it work?"

"Well, Dad, here is a little sketch I made of it. You simply grip the base of the jig in the jaws of the vise and adjust the screws to give the right taper both sideways and lengthways. I left them a little large for fitting, but I noticed they didn't get any fitting. The tool maker that was doing the job simply placed the base of the same jig on the magnetic table of the universal grinder and ground them to fit. He said he could do it that way better and quicker than he could file them and I believe him."

"Yes, John, you will find that jigs and fixtures are absolutely necessary for accurate repetition work and if you follow the practice of making a sketch of the essential features of jigs and fixtures as you come in contact with them you will soon have a very valuable collection, but look here, it's eleven o'clock, so off to bed. We will continue this talk on some future occasion."

CASE CARBONIZING

The Driver Harris Co., Harrison, N.J., have issued a very attractive book entitled Case Carbonizing. It contains one hundred and twelve pages 5 inches by 7 1-4 inches, and has 21 illustrations and several useful tables.

This is one of the most compact little books yet issued for the use of those interested in case-hardening or carbonizing. While primarily gotten up to call attention to the use of nichrome boxes and pots, it is not a mere advertising booklet, as the information is of general use to all those having to do with carbonizing or heat treatment of low-carbon steels.

It starts out with a chapter on case-carbonizing, divided into sections on the definition of case-hardening, its history, mechanics, oil tempering vs. case-hardening, requirements for case-hardening, quality of steel used, effect of temperature and time, pack-hardening. Chapter II, Cyanide-Hardening, gives details of the practice and formulas used for cyanide work and outlines its limitations. Chapter III, Gas-Hardening, covers the theory and use of various gases for case-hardening. Chapter IV, Lead-Hardening, tells of the use of the lead bath in connection with case-hardened work. The temperature range of the lead bath is given also. Chapter V., Carbonizing Containers, mentions and discusses the various kinds of containers and their merits or demerits. Chapter VI, Nichrome Commercial and Technical Data, gives the strength of nichrome, its acid-resisting properties and other features. Chapter VII, Cast Nichrome Containers, takes up cast nichrome for cyanide hardening, cast nichrome for pyrometer protection tubes, dipping baskets, additional uses of nichrome castings. Chapter VIII, Commercial Methods of Using Cast Nichrome, describes its uses for treating automobile starting and lighting equipment, studs, set-screws, small bolts, nuts, etc., ring gears for automobile differentials, roller bearings. The appendix is filled with tables of stock patterns and special container sizes. The latter is especially valuable for the man wanting containers to suit his particular requirements.

Discover Coal?—A report from Shelburne, Ont., says that on a farm near there a farmer claims to have discovered coal while drilling for water.

DEVELOPMENTS IN SHOP EQUIPMENT

CHUCKING MACHINE

The McDonough Manufacturing Co., Eau Claire, Wis., have placed on the market what is known as the Daniels automatic multiple spindle chucking machine. The illustration herewith not only shows the machine itself, but points out clearly various parts of decided interest.

The machine is designed to obtain the most efficient means of machining parts in large quantities, with the use of semi-skilled labor to operate the machine after it is set up and timed for the various operations. It has five tool carrying spindles and a blank station. The turret upon which the spindles are mounted, and whose axis is concentric with that of the table, does not revolve, but through its automatically controlled vertical movement, it feeds the tools to the work.

The table has six chucking positions and revolves step by step, bringing each chucking position successively into alignment with each spindle. The tools, mounted on the spindles, perform their different operations and a finished piece is removed when it is at the blank station and an unmachined piece takes its place. The time of machining a piece is the time of the longest operation, plus the time of one index.

Detailed Description

The spindles have a rapid approach to and a rapid reverse from the work. The spindle carrier is operated by means of a quadruple screw, operating through a bronze nut in the centre column.

The screw is revolved by means of a worm gear and worm and the worm by means of three friction clutches—one for rapid approach, one for the feed and one for a rapid reverse. The indexing of the table is also controlled by a friction clutch. By obtaining these movements through friction clutches, the machine is protected, for should a tool break and jam in the work, the feed pressure goes up and causes the feed friction to slip, and should the movement of the rapid approach or reverse or indexing mechanism of the table become jammed in any way, the friction clutches controlling these operations will slip, thus preventing damage.

The stopping, starting and tripping of the machine is controlled by two levers so placed that they are always within easy reach of the operator from the chucking position.

The Table

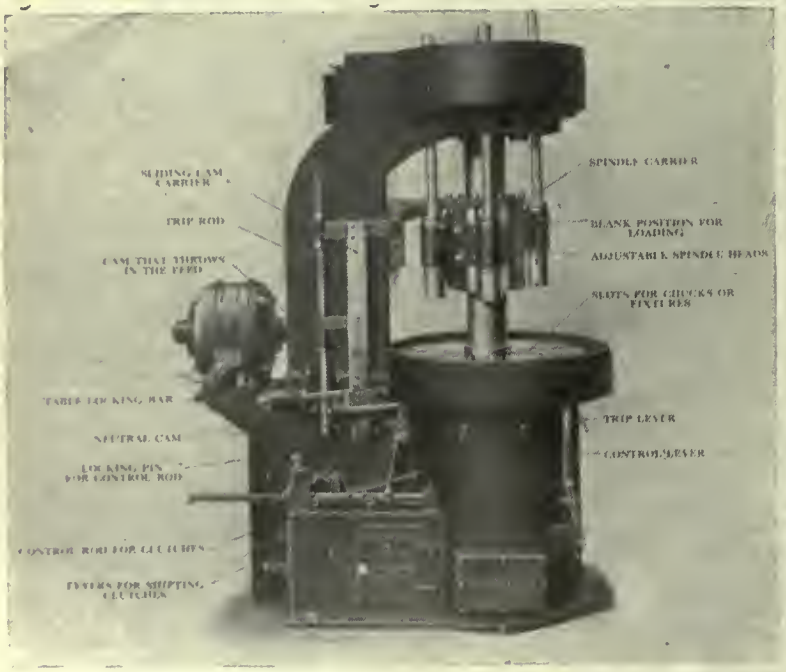
The table is 36 inches in diameter and six 10-inch chucks or workholders can be mounted on it. These chucks can be made larger, if necessary. The travel of the spindle carrier is 13 inches, it taking four inches of this vertical movement to withdraw the locating pin and to control the indexing of the table. The maximum distance between the spindle carrier and the table is 21 inches.

The machine will handle work from three to six inches in diameter and perform the following operations: cup turning, boring, facing, reaming, tapping with collapsible taps, and drilling multiple offset holes by attaching a multiple spindle auxiliary head to any of the spindles. The table can be set to index one, two, or three spaces.

The speeds are varied by means of change gears. One set controls the speed of all the spindles, which can be regulated to give a spindle speed from 30 to 300 revolutions per minute, all depending upon the work to be done. Each spindle has an individual set of change gears, which will vary the speeds of the spindles from one to three and one-half, so that each spindle can be given the most efficient speed for the particular operation performed by it. Change gears vary the feed from ⅜ of an inch to 4⅜ inches per minute.

The spindles are equipped with taper bushings that can be adjusted to compensate for any wear, and each spindle has an individual adjustment on the spindle carrier of nine inches. All the shafts and the feed screw are made of heat-treated chrome nickel steel. All of the gears are made of steel or bronze with the small important gears made of nickel steel and carbonized. All bearings are bushed with bronze bearings.

The machine can be used with countershaft, or direct motor drive, and uses a 10 h.p. constant speed motor. The net weight is 10,000 pounds, and the total projected floor space is 38 inches wide by 77 inches deep.



GENERAL VIEW OF CHUCKING MACHINE ILLUSTRATING POINTS OF INTEREST.

COMBINATION MELTING FURNACE

The Canadian Hanch Burner Co., Port Hope, Ont., have improved their combination melting furnaces in many ways, and for readers' benefit who may not know the particulars of this style of furnace, we append the following information. Their uses are varied, and they are adapted wherever lead and other soft metals have to be melted.

The illustration shows clearly the idea. It is actually two outfits in one,

a melting furnace, and a portable oil burner. The burner can be instantly detached if desired and used for a wide variety of purposes, such as melting babbitt out of bearings, heating bearings for rebabbitting, expanding to shrink fits, melting lead out of pipes, fitting joints, preheating for welding, etc., etc.

GENERAL VIEW OF THE OUTFIT.

The furnace illustrated is the smallest size with a 125 pound pot. This melts 100 pounds of lead in 14 minutes. The burner consumes 3 pints of kerosene per hour. With the larger furnaces 200 pounds of lead can be melted in 15 minutes, and 450 pounds in 20 minutes.

FLUE CLEANING RATTLER

The Baird Pneumatic Tool Co., Kansas City, U.S.A., have placed on the market a flue cleaning rattler and unloader as shown in accompanying sketch. This machine is a friction and not a drop rattler. It cleans by friction, first removing the scale, then using this scale in powdered form as a scouring medium.

It is capable of handling, at one rattling, a full set of boiler tubes averaging 250 to 300 flues, cleaning them throughout their entire length inside and out, in from one to six hours, depending upon the hardness of the scale. Any length flues up to 24 feet can be cleaned, the adjustment for length being obtained by a moveable piston head in the drum. A six-inch play permits of a slight lateral motion, but not enough to allow the flues to become tangled and destroyed.

No dust is allowed to escape into the shop as the scale is gradually worked to either end of the rattler, and from there into the dust rooms provided for its accommodation.

The cleaned flues are unloaded by being pushed from the rattler by compressed air out through an end door into a push car, ready to be safe ended and installed.

Power is applied to rattler by either belt or chain, and in some cases by direct motor drive. The machine is adapted for all classes of fire tube boiler flues, handling large diameter super-heater flues as efficiently as the smaller sizes.

NEW THINGS IN MACHINE TOOLS

GRINDING AND BUFFING MACHINE

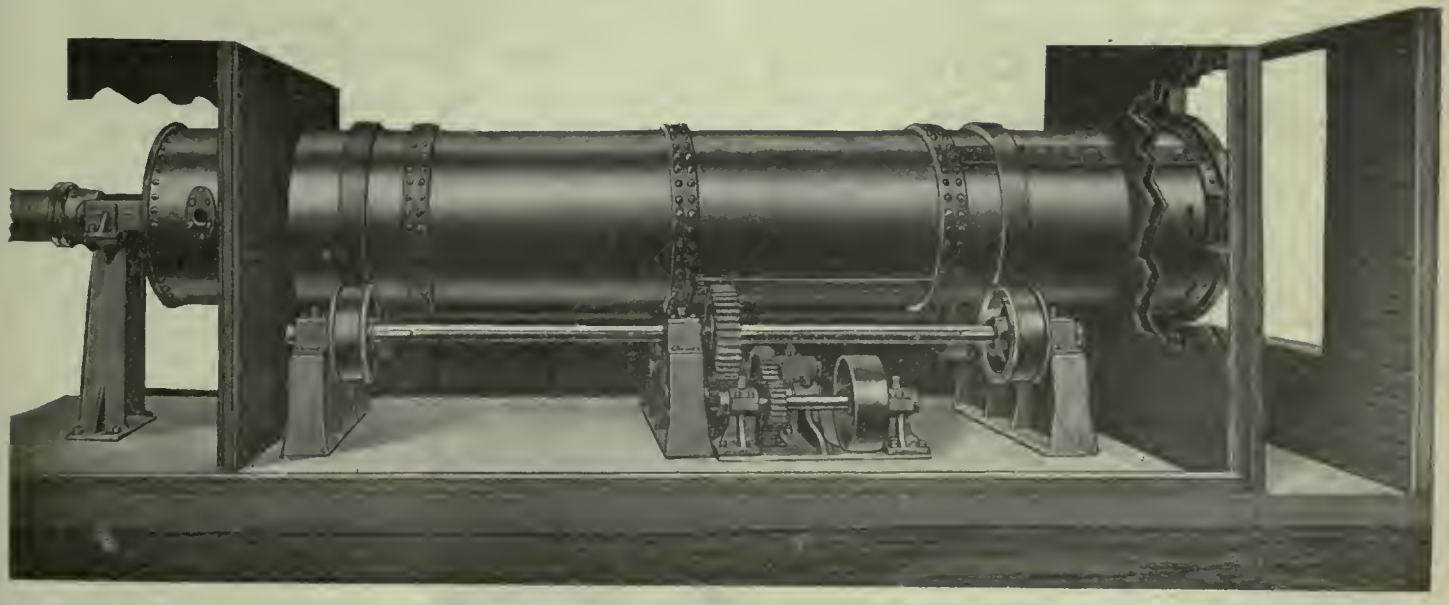
The Van Dorn Electric Tool Company, of Cleveland, Ohio, are now manufacturing a 1-h.p. heavy duty electric grinding and buffing machine adapted for floor, bench or aerial work. Motor ventilation is provided by means of a fan drawing air through screened openings at the rear of the frame. Interchangeable assembly provided for changing over from d.c. to a.c. at the minimum of expense. The speed on d.c. is 2,000 r.p.m. The shaft is mounted on ball bearings enclosed in dust-proof housings. The frame construction provides for work of long length being held parallel to the axis of the grinder. The floor type is fitted with foot-operated switch.

CHAMFERING MACHINE

The Grant Manufacturing and Machine Company, of Bridgeport, Conn., has recently produced an automatic double-spindle chamfering machine that is intended for chamfering simultaneously both ends of automobile piston pins, and on pins 5-8-inch in diameter and 3 inches long, it is claimed that a speed of 40 pins per minute can be maintained. Pins of the proper length are placed in a hopper from which they roll down a slight incline to the feeding mechanism, where they are taken, one at a time, and placed in a clamp which retains them while the cut is being made. Other uses may be made of the machine, such as drilling, facing or counterboring opposite ends of small work. Square or other shape work may be handled equally as well as round pins.

COUNTER-SINKING MACHINE

The Langelier Manufacturing Company, of Arlington, R.I., are now making a special line of opposed-spindle counter-sinking machine for centering or drilling both ends of small pins at the same time. The spindle at either end runs in phosphor-bronze bearings and operates at a speed of 2,000 r.p.m. The pulleys for the spindle drive are run on ball bearings and are located on stationary sleeves on the drill heads, thus eliminating any bending tendency on the spindles. Spindles are simultaneously operated by means of a hand lever. Adjustable stops are provided for feed control. The jig-heads, for holding the work, are actuated by a locking cam, and may be operated by hand or foot lever for releasing the work. The coolant is controlled automatically so as to flow only when the tools are cutting.



FLUE CLEANING RATTLER AS INSTALLED INSIDE A PLANT WITH DUST ROOMS ON THE END.

Market Tendencies

CANADIAN buyers are leaving the premium steel mills, and prices of these rollers will likely sag in accordance. It is reported that sheets from some of the corporation mills are arriving freely now, and in some cases there are applications for cancellations.

There is nothing to indicate that anything approaching a crash or even a sudden drop is coming in the steel market. There is a lot of business on the books of the mills, especially the corporation's.

It is much better that prices should step down little by little than that there should be a sudden drop. Steel prices, apart from the schedule of the premium mills, have not been high.

We are approaching a stage in the markets where it may be possible to once more do business on the basis of value, taking as a definition of value the following:—

> "The price arrived at between the least urgent buyer and the least urgent seller."

For years now in many lines of steel, iron and machine tools there have been only a few months when there were any "least urgent buyers." The market has been full of buyers, and urgency has been one of their outstanding, rather than absent qualities.

When we get to the stage, and we are now very close to it, where two or three men present the claims of an article of equal merit, the matter of price is bound to enter into the sale to a greater extent than it has since 1914. There have been years when it can truly be said that price was one of the least considerations. It should never be allowed to dominate the situation, but in the natural course of events it will become a greater factor from now on than it has been for many years and months past.

The manager of a large Canadian concern, after a prolonged visit to Western Canada, and points in United States, has this to say:—"You can look long and hard before you will find a better country than Canada. We are in better shape than we realize. There is a lot of good, legitimate business moving, in spite of tight credits, and the bad spots exist mostly in the brain cells of some of the croakers."

"I am afraid the high wages the apprentices get now has lowered the desire for more mechanical knowledge."

THIS statement was made by one of the apprentice instructors on a Canadian railroad. It was put down in writing as the firm belief of the man who had made the remark.

It cannot be said that he is talking at random, because the statement was made in all seriousness. He comes in contact with the apprentices daily, and has a good opportunity to see the development of any tendency that may become apparent in the training of apprentices.

The high pay for apprentices is part of the system wished on us by the war shops. These same practices spoiled good shop training.

The superintendent of one of the largest Canadian car shops told this paper that the high rate of pay for apprentices had not improved the work of the apprentices; had not brought in lads with any better education; had not increased their desire to go on and become high-class men.

Instead, it had worked the very opposite in many instances. Apprentices in their second and third years came to the point where they were making enough money to take care of themselves. They were independent of home influence and parental discipline just at a time when many a boy needs to be led to the shed and told exactly "where he gets off at."

The added money was not bringing any better work. It may have contributed to meeting the added cost of keeping the apprentice boys; apart from that it was sheer waste.

Industry is changing, and specialists are in demand. Firms want mass production. They desire speed and excellence in each minute operation. In the majority of these training is not necessary. A few weeks' practice fills the bill. The money is there without the skill that comes of long training. The finer points of design may be looked after by those who care to bother; mathematics and calculations can be attended to by others who foolishly follow this branch. But why bother about these matters? Here's a little job that needs no training in particular. Why, in a few weeks or so, one can make as much money as the man who learns his trade and gets a thorough mechanical training.

Quite so, and some fine morning you come down to find that the little job is not needed any more. There is no call for it.

What then? You are in the class of the thousands of unskilled, "looking for a job," and thankful to get one at any price.

Now the proposition is here, and it is as plain as the nose on your face:—

Shops that are specializing in order to get mass production are bedevilling the mechanical field in the broad sense, unless they face their full responsibility in the matter. They must build up the ranks of trained and skilled men to as great an extent as they are making that fine training and skill unnecessary by their shop practice. Unless they do this they are going to find, in a few years—and it may be very few—that they will have a famine of tool makers, maintenance men, and designers.

The situation is real—it is serious, and it is one that cannot be sacrificed to the desire of any branch of industry to secure great and record-breaking production at the expense of a well trained, thoroughly educated and capable mechanical population.

Grinding at Speed of 100,000 Revolutions Per Minute

THE present-day tendency towards ever increasing speed has been often deplored by the more staid and conservative elements of the community. Where the endeavor to procure speed has only been actuated by a desire for new sensations, this disapproval is, perhaps, well merited. All speeding-up processes are not developed with such meretricious objects, and in the field of industry speed is a desirable thing, both in general production and in the details which make rapid production possible. From this necessity has arisen the various high speed machine tools, and high speed cutting steel, with which we have all become familiar in recent times.

To what extent this tendency has developed was forcibly brought home to us by an account of a high speed grinding spindle attachment recently exhibited by a well-known British firm of tool makers. Grinding is one of the operations in metal working where speed is of great value, and especially on small internal work, such as lapping gauges, internal tapers, bushings for precision tools, etc. The wheels employed are of necessity very small, and this permits of the attainment of high speeds. The higher the speed of the abrasive surface, the less tendency will there be for the surface of the metal being dragged, and thus roughened, a condition strictly to be guarded against.

Practice in grinding had reached a point where these wheels had been revolved at 75,000 revolutions per minute, which is a very respectable rate for any spindle to revolve. The spindle we are alluding to exceeds this speed by 33 1-3 per cent. That is, it is guaranteed to be capable of running safely at 100,000 revolutions, and has been run at a speed of 104,000 revolutions per minute.

This is getting to a point where the mind fails to grasp the significance of the figures involved at the first glance. Try to picture a small spindle and the wheel mounted on it which makes a complete revolution in just .0006 of a second. If the spindle on which the wheel is mounted is one-half inch in diameter, its circumference would cover a distance equal to 13,090 feet, or almost 2½ miles per minute. A locomotive with a 5 feet diameter driving wheel would have to turn that wheel 833 times a minute to attain the same distance in the same time. The spindle, of course, will, on the smaller sizes of wheels, be of less diameter than one-half inch, because it is very obvious that with a wheel of ½ inch or ⅝ inch diameter, one could not well have a ½ inch spindle.

The wheels for this speed must be of good construction, for they will have to resist the force tending to tear them apart, due to the speed. Of course, they will be of no great weight, probably averaging 2 to 4 ounces. Suppose the wheel weighs only 2 ounces, and is of one inch diameter, the force tending to make it fly off at a tangent, or the centrifugal force would be equal to about 18,000 lbs.

These figures seem hard to realize, and they serve to show what has been reached in engineering practice when such speeds can be employed with perfect safety. There can be no doubts as to the material employed, or the manufacturing methods used, when speeds of one hundred thousand revolutions per minute can be guaranteed.

Making It Harder to Do Business With Canadian Firms

THE Canadian Association of British Manufacturers and their representatives are doing their best to bring to the attention of the British houses any incidents or practices that retard the development of business in Canada.

The terms insisted upon by some of the British firms are found to be particularly objectionable, and are set forth in a little booklet called "Sales Craft," issued by the Toronto branch of the association:

"A Canadian manufacturer of steel and iron products recently had occasion to replenish his stock of certain materials used in various articles manufactured in his mills, and as there are only two sources of supply, Great Britain and France, and the producers few in number, the business was offered to a United Kingdom manufacturer. A natural preference in the matter of trading, national bias in conjunction with Imperial sentiment, prompted this loyalty to British enterprise. The offer, as many another prospective Canadian purchaser has been forced to testify, was not met in kind, the intending customer being informed that the order could only be undertaken on the basis of "cash with order" or by the instituting of a "letter of credit" with a London banking house to the order of the U. K. manufacturer. Such stipulations were, and are, quite out of the question, as no responsible Canadian business house will consent to do business under those conditions nor submit to the dictation of trading on terms of that nature. The result of the matter was the booking of the order by a French manufacturer on open account at sixty days dating. Hence, for ten years past this business, though offered repeatedly to a British manufacturer and more than once to the same house, has been executed in France. There is no question as to financial standing of the Canadian firm, it is quite good and annually improving—the firm buying largely in the United States, but nothing in England. In a recent conversation, the head of the business expressed an opinion, that is in no sense isolated, that United Kingdom manufacturers and business houses can expect no great extension of trade in this country until they accredit to Canadian business men a measure of integrity beyond that of a band of robbers. In this one instance, orders amounting to practically $50,000.00 have been lost to British mills merely on a question of terms of sale."

The same publication goes on to point out that the time extended to Canadian customers by the American manufacturers of iron and steel products for payment of accounts differs somewhat in various mills and also in some States, but the most usual and generally accepted terms are 2 per cent. for cash in 30 days or net in 60 days. In some instances a cash discount of 2½ per cent. is conceded and others call for cash in 20 days, less 3 per cent. With some manufacturers of machinery the terms are quite elastic and large buyers of good credit can obtain very favorable concessions. The method of collecting bills by sight or demand draft against documents or other similar methods are practically unknown to American shippers, who are inclined to figure that if an account is a doubtful risk on regular credit, it would be a precarious venture on any, the object being to make the terms of payment the least possible obstruction in the field of distribution.

A visitor from South Africa tells us that during the war they paid as high as $490 per ton for steel plate. Which leads one to think that if there were much business in plate carried on there wouldn't be much left of the famous Gold Coast in that country.

Here is the opinion of another Canadian manufacturer whose product needs a lot of money before being put on the market, there is no trouble selling, but there is trouble in financing just now. He says: "Credit is the thing that is bothering us now. There is plenty of business. In fact we could run our place twenty-four hours a day were we able to get the material and the help from our bank. We look to see the move toward price reduction continue. In our lines falling prices of material do not worry us as we tender for work, and then cover ourselves for everything we need

MARKET DEVELOPMENTS

Canadians Leaving the Premium Steel Markets

Some High Priced Stuff Still in the Warehouses Here—Cancellations Asked on Some Lines of Sheets, But in Other Lines There is Still a Very Keen Demand for Many Lines of Steel

THE market in steel is running pretty true to expectations, and one development of the past week has been that Canadian buyers are deserting the premium mills. Although there is still a demand for the products of these mills the chance of financing any considerable tonnage at a high figure is too speculative to be inviting. Steel sheets are showing a better delivery, but as a general thing the car situation, judged by the recent performance, has been worse instead of better. Some reports have it that applications are being made to the mills for cancellation on sheets, but it is doubtful if there will be any concession in this line. Cancellations are the one thing that the whole business fabric will likely fight hard to prevent. Once they start they are too far-reaching in their influence, and the feeling is that the time to stop them is at the start, and this can probably be done, as nearly all business has been booked in the last six months or a year on the no-cancellation understanding.

There is no large buying in the machine tool market, although several of the houses say they have done a good business in the last month, and are finding a number of good inquiries coming into the market. Buyers anticipate some announcement in regard to price adjustment, and while this has the tendency of slowing business generally, it does not cancel the orders, but merely postpones their coming into the market. So far there has been no general move on the part of the machine tool builders to make concessions, although stock must be accumulating fairly rapidly at some of the plants now.

MONTREAL PRICES REMAIN VERY FIRM IN NEARLY EVERY LINE

Special to CANADIAN MACHINERY.

MONTREAL, Que., Oct. 14.—Contrary to the expectations that prices would develop a tendency to lower levels, the market in general retains a firmness that apparently indicates that the time has not yet arrived for the cutting into the prevailing costs of materials. While it is understood that the stocks of consumers and dealers are not very large the supplies in the hands of producers and the orders on the books are of such a character that producers and likewise many of the jobbers would not care to see any sudden decline in present quotations. While easier conditions are a possibility, the strength of the present situation appears ample to sustain the belief that no drastic reduction will take place for some time. Some dealers are looking forward for a definite revision about the New Year, but any outward sign of early change is noticeably absent. The standpat attitude is in the face of the universal report that activities in many directions are slackening.

Firmness Likely to Continue

"Buyers of steel and other metal lines are not looking for supplies beyond their present requirements, but aside from a few isolated cases there is little to show that consumers are holding off buying in the hope that prices are coming down. The trade as a whole realize the uncertainty of the early future but at the same time recognize the conditions existing in the steel industry and kindred activities and while appreciating the advantages of lower priced commodities cannot very well see how any excessive decline can be successfully carried out at present or in the immediate future. Of course we are living in times when overnight changes are not only possible but frequently foregone conclusions, and it is this knowledge that prevents any reliable prediction of the trend of the market. We look for a fairly steady market for some little time." This statement by a dealer here would indicate that, under the atmosphere of uncertainty, there exists a general belief that conditions as now obtaining in the industrial field would not permit of any drastic lowering of price quotations on any of the regular lines of steel materials. The new demand for steels is undoubtedly lighter, but requirements of customers are still ample to absorb the bulk of the material coming through from the mills. The transportation problem is much better and delivery is becoming quite normal. This condition will accomplish much in bringing about a more reliable basis of working operations and aid in removing the uncertainty that prevails in all branches of activity. There is still a marked scarcity of cold rolled steel and some sizes are impossible to secure. Plates are more plentiful and sheet supply is showing gradual improvement.

Supply Movement Good

"The bulk of the machine tool movement is in the way of the smaller equipment, and while sales are not heavy the volume of business is quite seasonable, but probably below normal for this time of the year," remarked a dealer this morning. "It requires considerable more effort to sell equipment today, not that the buyer does not need the machinery, but rather because many are content to worry along with what they have in the hope that better prices will obtain in a few months." The dealer added, however, that apart from the acquisition of machine tools the buying of supplies continues in fair volume.

Non-ferrous Metals Lower

"The situation continues very quiet and movement of scrap is exceedingly light. Steels and irons are very dull and weakness has developed in non-ferrous lines." In addition to this statement the dealer intimated that foundry operations had fallen off during the week but expected a renewal of activity for the coming week. The best business of the present is done in cast iron scrap and stove plate. Coppers are lower by one cent, light being quoted at 14 cents and heavy and crucible at 17 cents per lb. Brass is down a half, light bringing 6½ cents and medium 7½ cents per lb. Scrap zinc on a similar decline is quoted at 6 cents per lb.

NO REAL SLUMP IN TOOL MARKET

Firms Report That Signs Point to Much Better Booking in the Near Future

TORONTO.—There are some reports of cancellations this week in the steel business, but the chances are that the firms making application will not be allowed to cancel as the business for the most part has been placed under a non-cancellation clause. There are some suggestions now on the part of sellers that some industries have during the past six months or so resorted to pyramiding of orders in the hope of getting a fair amount through quickly, that is they would come on the company's books for two or three times what they actually needed in the hope of getting delivery of a portion of the order, which would be about their real wants. There is nothing to substantiate such a charge, but it is a report in the market.

The machine tool market believes that the turning point in the market situation is here, or very close at hand. None of the firms report very large orders in the district, but some of them tell of a good month's business closed for September, now that the figures have been added up. In one case a dealer had an enquiry for a good sized string of equipment, that looked more like an order from a war shop than anything we have seen for some days.

But the important thing seems to be prices in the machine tool market just now. On the face of it there seems to be no good reason why prices should come down, and in one isolated case one maker has actually announced an increase in one line. But schedules for delivery are getting much quicker, and some tools can be ordered out of stock now for the first time in a good many months, or years, for that matter.

There is an expectation on the part of buyers that there will be a reduction in price. Dealers admit that this feeling is holding back quite a bit of buying that is not of the urgent sort. The belief is that by holding off for a while longer there will be a better price than by coming into the tool market now.

One dealer sized it up this way: "Some of the newer concerns that sprang up with the war will likely be the first to make some cut in their prices. They will have to do it sooner or later because they cannot get the backing to go on and pile up for stock, so they must either cut or curtail operations, and when they start to cut down operations they will find that their manufacturing costs will grow higher instead of getting less. I do not expect reductions for some time from the older firms in the machine tool business. We have nothing from our principals that would lead us to believe that reductions are coming, neither do I think that a cut in prices now would result in selling many more tools. We have no applications for cancellations on business that is on our books, neither is there any request for reductions in prices on this business."

The sale of motors in this district is being more or less interfered with by reason of the scarcity of power. There is a fair demand for motors of the 60-cycle type, because power of that frequency is more available, but for motors of the 25-cycle type the sale is not so good.

Many of the firms handling both wood and metal working machinery report a very good movement in wood working machinery, and say that the business is running well ahead of the figures for the same period last season.

The Steel Market

Some reports are heard of attempts to stop some large deliveries in the steel market, this extending even to sheets, which have been a much sought after line for months past. This does not mean that the market is full of sheets, but it does mean that some lines find now that they have bought well beyond their requirements. Most of this business is taken on the understanding that a contract is a contract, and the chances are that the deliveries will be made and the buyers will have to deal with the financing as best they can. There should not be much difficulty in disposing of sheets yet, as there is a big demand, according to reports, and most of the available material is at a high figure from the premium mills.

The change in the steel market is coming surely, if slowly. As has been predicted in these columns, and in our Pittsburgh letter for some months, the premium market is the first place to sag. Canadian warehouses that have been drawing heavily on the premium rollers for their supplies have simply ceased to buy from them. These warehouses have something to sell, and for the present they are not taking on any more material. There is bound to be an effect on the independent schedules, and these mills will have to keep their plants going, and the one way they can do this is by coming down on their prices. The prospects seem to be that it will be only a short time before their figures will be down to the level of the Steel Corporation.

Cold rolled shafting is a scarce article. There are plenty of places where a good tonnage can be taken on if some mill can be located that will handle the business. Several machinery houses that make it a business to instal a plant complete, are in a bad way to get shafting, and the chances are that they will find little improvement for some time yet.

Boiler tubes are not much better, in fact they are about the one black spot on the map. There is not the finishing capacity for them that there is for sheets, for instance, so it is impossible for the plants in operation to catch up with the business that is offering and urgently required. "If anything the tube situation seems to be getting worse," was the cheering comment of one dealer this morning. "Our advice is that there will be little improvement, and in the meantime there are a large number of plants that are urgently in need of tubes."

POINTS IN WEEK'S MARKETING NOTES

The steel buyers in Canada are leaving the premium mills as fast as they can, there being too much risk attached to financing any more high priced material.

Boiler tubes and cold rolled shafting are the black spots in the steel market just now, and there is a big unfilled demand for both.

Machine tool houses report that inquiries are better, and some nice lists are coming into the market. The amount of business being closed is not large yet, but the prospects for a good season's trade are bright.

The scrap metal market is not recovering. Dealers are not anxious to buy, and those wanting to sell fear to do so as concessions are about the only way to sell.

Montreal reports that dealers there do not expect a revision of prices in either steel or tools before the first of the year.

The New York machine tool market continues very quiet, and purchasers realize that the market is theirs more than it has been for many months.

Some applications are made for cancellation of orders for steel, but there is not much chance of these being granted except under very exceptional circumstances.

SAYS COAL PRICES NOT JUSTIFIED

Values Should Come Down in a Short Time Is the Claim Now Made

Washington.—Reductions in coal prices may be expected soon, Charles L. Couch, president of the American Wholesale Coal Association, announced.

Mr. Couch, following a meeting of the executive committee of the organization at which the entire coal situation was canvassed, declared that it is the opinion of the committee that a great change in the whole coal market situation is imminent. He suggested to buyers of bituminous coal who have a month's supply in storage to confine their purchases to immediate needs.

Prices which have prevailed for bituminous coal, Mr. Couch declared, are not justified by the present satisfactory production.

HERE ARE THE HIGH SPOTS AND THE LOW ONES IN N.Y. MARKET

Special to CANADIAN MACHINERY.

NEW YORK, Oct. 14.—The machine-tool situation is made up of somewhat contradictory elements, which are both favorable and unfavorable. It must be admitted that at the moment the unfavorable factors are much to the forefront. Among these factors are:

(1) A falling off in business during the past few months to an extent that has placed some machine-tool manufacturers in a position where they have no orders ahead and are making tools for stock. This has resulted in curtailment of operations, which in a few instances has caused reduction of the working days from six to four days a week.

(2) The expectation of buyers is that machine-tool manufacturers will lower their selling prices. While most prices are holding firm, there has been a reduction of 15 per cent. in one make of internal grinding machines, and in a great many instances buyers have insisted that sellers guarantee their prices when sales are made.

(3) The credit situation is still an important factor in the situation. Not only are collections slow on old accounts, but manufacturers generally have little liquid capital with which to finance the purchase of new shop equipment.

The above factors, together with a degree of uncertainty as to the course of business in the next few months, are mainly responsible for the decided slump in machine-tool buying. In spite of present conditions, discouraging as they are in many respects, there is a considerable degree of optimism. This optimism is based largely on the following premises:

(1) That machine-tool prices cannot decline very far, due to the continued high costs, which to a certain extent will remain high because of the fact, generally recognized, that labor costs will not come down much, if any, in the immediate future.

(2) The fact that only a few weeks remain before the Presidential election, which is nearly always a disturbing influence in business.

(3) The fact that the railroads of the country must eventually buy very heavily. Their shop equipment is in deplorable condition, and the mechanical departments are committed to extensive purchases as soon as the finances are available; when this time will come is somewhat in doubt, but it is expected that by the first of the year or shortly thereafter, railroad purchasing will be begun on a fairly large scale.

(4) The fact that, despite the lack of actual orders, there are many pending inquiries, which represent actual needs; buying against these inquiries will result, it is expected, when the money situation has improved, and when a confidence in the price situation has been restored.

In addition to the above may be mentioned the fact that it is generally believed that the automobile industry, by reducing prices on cars, has gotten past the worst phase of its depression, and that sales of automobiles should show an increase during the next six months that will bring automobile manufacturers back into the market as buyers in the spring, at the latest, possibly before.

Nowhere is there any denial of the fact that business was due for a slump, and it is generally believed that the present depression will be a good thing. A readjustment had to come, but it is contended that the period of reaction will be relatively brief, and that next year should be an exceedingly prosperous one.

This is the way the machine-tool trade sees the situation. The significant thing is that, although buying of tools is at the lowest point in many years, there should be such general confidence in the future; that is the future beyond the next few months.

There has been a little business in the last week, but nothing of importance. An inquiry for about 125 machines comes from the Brazil Railway, but actual purchases may be deferred for two or three months.

PIG IRON TRADE

Pig iron prices are very uncertain. Buyers are waiting and the absence of direct sales by producers leaves market level in doubt. The market at Philadelphia is very quiet.

Consumers and producers on the Chicago market are waiting for developments and it has become a game to see which can hold out the longest before making a definite move. Practically no buying for 1921 delivery is being done. While the basic market has weakened to some extent its level is still a matter of speculation, but it is understood that some furnaces will do business at $46 or less, but they want offers of definite business before making a quotation.

Little activity is shown on the Boston market excepting unusually good delivery. The feeling is that the present is not the time to buy for the first half. Foundries in general are operating at full capacity and have sufficient on hand for the remainder of the year.

Demand is very limited in the New York district and all the iron sold was for prompt and nearby shipment.

Owing to the Buffalo market being disturbed by reports of sales at considerably under quotations, furnace men are watching the situation with very uncertain minds. Very little selling is being done.

There is very little activity in the pig iron market in the Birmingham district.

STEEL CORPORATION PRICES ARE NOT LIKELY TO YIELD—INDEPENDENTS WILL

Special to CANADIAN MACHINERY.

PITTSBURGH, Oct. 14.—While the iron and steel market is in process of readjustment not much change occurs from week to week. The various stages of readjustment are likely to be passed through in much the same manner that has been exhibited at various times in the past when a buying movement was ended and a period of slack operation and declining prices had to intervene before business was ready to go ahead again. There is one difference of some consequence, however, that being that the present re-adjustment in prices and decline in industrial activity is a general one in all lines of business, and may even be less marked in steel than in other commodities, whereas in the past the steel market has undergone wider swings than commodities in general. For instance, after the panic of October, 1907, the iron and steel industry was very much depressed for about a year and a half, whereas business in general decreased much less. This time the iron and steel industry may get off more easily than other industries, for everyone is now talking about price declines and heavy declines, in all sorts of commodities.

The fact that steel prices have not declined in any important way thus far, except for the disappearance of the particularly high prices, involving premiums for very early shipment, does not, of course, mean that the steel industry will get through this period without any price re-adjustment. The market is simply slow in responding to the disappearance of aggressive buying, this being for the reason that the mills, with occasional exceptions, are very well supplied with contracts, and to reduce prices would be to jeopardize the contracts. By price cutting the mills would lose much more in contract business, through cancellations and postponements, than they would gain by securing new orders.

It still remains the prospect, according to the judgment of nearly everyone in the trade, that the Steel Corporation's prices will not yield, the re-adjustment being confined to the independents. It is considered certain that the independent prices will recede to the Steel Corporation levels, and a common view is that if they go as far as that they will go somewhat farther, the independents cutting under the Steel Corporation prices, in order to buy their way into the market again, for patrons of independents who have had to pay higher prices for months than patrons of the Steel Corporation are not likely to be anxious to place orders with independents at Steel Corporation prices when they have a wide latitude of choice as to where they will place their orders.

There is even a little talk of the Steel Corporation advancing its own prices a trifle, for the double reason that the corporation suffers a loss of several tens of millions of dollars a year by reason of the freight rate advances last Au-

gust, and may feel that it should recoup, while the independents might be more ready to adopt Steel Corporation prices if a little concession were made to the independents by way of advances of say $3 or $4 a ton. The independent decline would in that case be much greater than the Steel Corporation advance, but the thing would look somewhat like a compromise, and would be less distasteful to the independents, most of whom have been preaching more or less constantly for a year or so that the Steel Corporation would be forced to advance its prices.

Production

Production of steel ingots in the United States in 1919 is officially reported at 33,694,795 gross tons, against the record of 43,619,200 tons made in 1917. Capacity lies somewhere between 50,000,000 and 55,000,000 tons, given fair manufacturing conditions, so that operations in 1919 barely averaged two-thirds of capacity. For this defection lack of orders was chiefly responsible. The strike that began September 22 restricted output considerably, but it is doubtful whether if there had been no strike, the industry would have operated at capacity, though capacity operations either late last year or early this year.

An interesting point in the statistics is that the Steel Corporation produced 51.0 per cent. of the steel ingot output in 1919, against a proportion of 45.5 per cent. in 1918. The lower percentage is representative of the Steel Corporation's relative capacity, rather than the higher percentage. In the fore part of 1919 the Steel Corporation had much less restriction of output than the independents, due to the fact that the Steel Corporation late in the period of hostilities forecast the future properly, and quietly booked business at prices attractive to the buyer, on the understanding that shipment would be made some time after the war. During the period of Government regulation such orders would fall in Class D, the steel that could be shipped after all priorities and preferences had been taken eare of, and of course practically no Class D was shipped as long as the war requirements lasted. The independents either failed to consider the matter at all, or thought they would be able to secure higher prices when the war restrictions were removed. The strike was probably another cause for the Steel Corporation making more than its normal proportion of the 1919 steel output, through the corporation being slightly less affected by the strike than the independents, even though the strike leaders acted as though they were directing the strike particularly against the independents.

Other production items for 1919 were: Steel castings, 976,437 tons; rolled iron, 1,059,451 tons; rolled steel, 24,042,000 tons.

The report of steel ingot production in September shows that the same rate obtained as in August, about 42,700,000 tons a year. There had been rather a sharp increase from July to August, and the failure of September to show a further increase was probably due to some of the mills being under less pressure from their customers for deliveries, since manufacturing conditions were improved and some mills, well enough supplied with orders, increased their production. The cases of mill operations being restricted by the state of order books are still exceptional, and it remains the prediction that this month will show an increase in tonnage output. This month will probably be the turning point in output, with declining production afterward until the general industrial readjustment is completed and business starts growing more active again.

Whether the readjustment will require three months or six months or a longer period is thus far only a matter of conjecture.

Pig Iron

The pig iron market has been so extremely quiet that new price levels have not been clearly developed. Everyone recognizes that the prices to which the market advanced in August, $48.50, valley, for Bessemer and basic, and $50 for foundry and malleable, and which were maintained fairly well through September, are booked to yield to much lower prices, but it requires actual transactions to show where values really stand. It is reported that a middle interest bought 3,000 tons of basic iron from a valley furnace at $45, selling 1,000 tons to a valley consumer at $46, and selling the other 2,000 tons in the east. Other buyers, however, expect to do much lower prices, possibly as low as $40. As noted in last report, foundry iron became quotable at $47, valley, instead of $50, on a small transaction, but nobody else seems willing to pay as much as $47.

U.S. SCRAP METAL

The decline continues in practically all grades of iron and steel scrap at Chicago. Much of this is due to the efforts to get under cover material reaching them from outside sources for which they have no means for disposal.

On the Boston market buying is limited almost entirely to a few dealers who have old orders to fill. One of the largest interests is refusing to buy. There is no demand for heavy melting steel.

Prices continue to fall in the local iron and steel market at New York. Over half of them have dropped from 50 cents to $1.50. Dealers say that with the exception of car wheels, which are never very plentiful, they are able to obtain supplies without difficulty.

The unsettled condition of the automobile industry following reduction in prices is largely the cause of the dull scrap market at Detroit. The auto factories are the chief consumers of iron and steel in Detroit and the conditions in the automobile trade are expected to be reflected in the scrap iron market for some time.

The easier tone lately in the markets generally has resulted in depressing the scrap trade in Philadelphia. Eastern consumers practically refuse to buy. No activity is expected on the Pittsburgh market until after the presidential election. Consumers are well covered and with few exceptions are getting good deliveries. Inquiries are limited.

The Southern market is reported as weak. In some cases melters are asking that shipments on contracts be held up.

THE STEEL WORLD IS WAITING TO HEAR FROM JUDGE GARY

New York.—Wall Street looks forward to Judge Gary's speech before the American Iron and Steel Institute on October 22 at the Hotel Commodore for a cue as to the true situation in the steel industry. Judge Gary reiterated yesterday his declaration to give no hint of his views before making that speech. Charles M. Schwab, at his country home in Loretto, Pa., declared that the steel industry was in a good, healthy state. "The conditions which make necessary a reduction in prices in certain lines and with certain companies will also tend to lower costs and increased production and will make for stability and normal operations," he declared. "The railroads of the country in normal times and under normal conditions consume about one-third of all the steel produced. Railroads during the past five years have ordered nothing like their usual amount and this deficiency of past years will have to be made up, which, added to their usual consumption, will keep the steel business steady and normal. The same conditions apply to building requirements and other lines of trade."

NEW CATALOGUE

The Armstrong Bros. Tool Co., Chicago, Ill., have issued a new catalogue, B 20. This catalogue embodies and makes effective various changes in list prices, and it is suggested by the concern that all previous lists be destroyed.

The book contains 143 pages of real live information regarding their varied line of tool holders, boring tools, lathe tool sets, grinding holders, rachet drills, C clamps, ordinary clamps, lathe dogs, wrenches, etc., etc.

For the convenience of the automotive trade they have segregated a special section devoted to drop-forged wrenches for automotive use. A copy of this book may be had upon request.

Handling Two Iron Discs on Production Basis

The Advantage of Combining Machining Operations is Self Apparent in This Material—The Same Principle Could Well Be Adapted to Other Lines, and This Article May Start You Thinking

By F. SCRIBER

AN example of how two cast iron discs are handled as one, which has the advantage of combining the machining operations, is the subject of this article and Fig. 1 illustrates the disc, the drawing at the left being a view of finished disc. It will be noticed that the disc is beveled and has a flange cast on it. At the right of Fig. 1 is shown how two of these discs are cast together, while the description which follows will make obvious the manner of handling the same on a production basis.

Having the two discs cast together the first operation consists of gripping the work on the periphery of the two flanges, and in a three-jawed chuck. The hole is now machined and both hubs faced. The next operation consists of turning the two flanges, while at the third operation facilities are provided for machining both beveled surfaces and facing of flanges. The last operation of importance is milling the three elongated slots in the beveled face, and this is followed by cutting the discs apart and facing them true.

Referring back to the first operation, the tools used are illustrated in Fig. 2. A represents the chuck jaws in which the work is gripped, this operation being performed in a turret lathe. In the first turret, face tools as shown are used, these being a short drill B for spot drilling the hole, and a cutter C for facing the boss. Both tools are held by suitable screws in the holder D, this in turn being held in the turret while the bushing E is used to securely grip the drill. Another feature of this set-up is the back facing cutter F which is operated through the

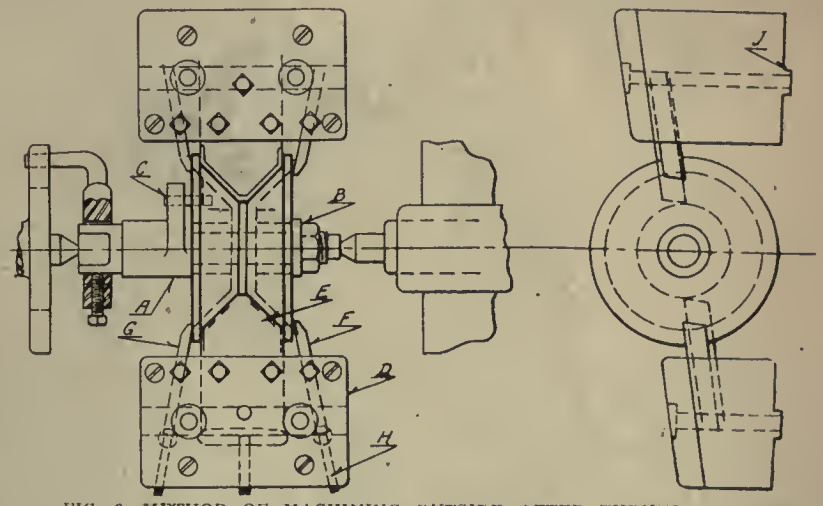

FIG. 3—METHOD OF MACHINING OUTSIDE AFTER TURNING FLANGES.

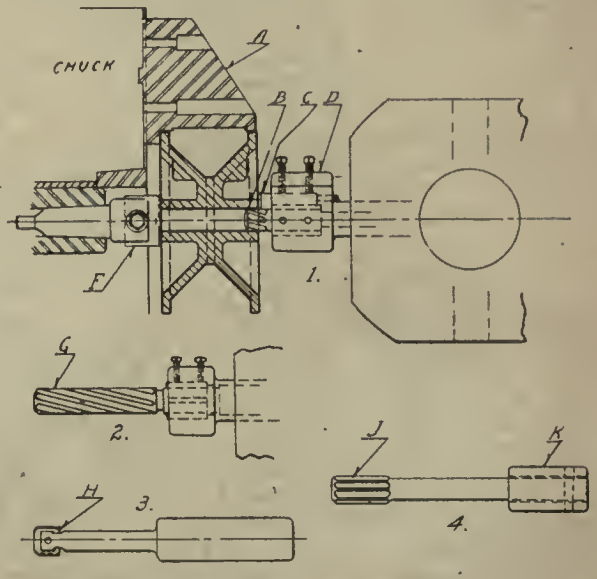

FIG. 2—FIRST OPERATION FOR MACHINING BEVELED DISCS.

spindle of the machine for facing the inner hub at the same time as the spot drilling and facing at the opposite end are being performed.

In the second turret, is a longer three-lipped drill G, which is of course used for opening out the hole, it being apparent from this that hole is cast rough in the discs. In the third turret the boring bar and cutter H are held, this cutter being of the flat type and it is used for enlarging the hole after drill has been passed through, thereby leaving a fairly accurate and true hole which is afterwards reamed by the machine reamer J, shown below, which is held in the fourth turret. This reamer is carried in the bushing K, which allows it to float slightly as is common for this class of work.

Before proceeding with the next operation of importance it is necessary to turn the two flanges on the discs, and this is done by driving a plain arbor in the work and machining in the customary manner between centres. When machining the beveled surfaces on these two combined discs it is necessary that each piece be located on the arbor in exactly the same relation to the cross-slide of the lathe as its predecessor, thereby eliminating the necessity of moving the cross-slide of the machine before making each cut. This is nicely taken care of with a sufficient degree of accuracy by providing a special arbor A. The work is held on the arbor against a shoulder by the nut and washer B, while a lug on the arbor carries a pin C which comes against another lug on the inside of the disc and acts as a driver for the same against the thrust of the cutting tools.

The machine used at this time is a lathe with a heavy cross-slide which carries tools on the front and rear side of the work. It is obvious that the arbor is held between centres and is driven by a dog in the usual manner. The block D on the front of the cross-slide contains a flat cutter E for rough facing the two beveled surfaces and the inner sides of the flanges. This cutter is notched to break apart the broad chips which would otherwise form on account of the wide cut, while cutters F and G face the outer sides of both flanges.

These three cutters are held at a five degree angle in the cross-slide block by square head screws and are adjusted by means of the headless screws H. On the rear side of the cross-slide is a similar block, this likewise carrying three tools, and is used for finishing the same surfaces. The cutter which machines the beveled surfaces at this time has no notches cut in it. These blocks are held to the cross-slide by means of tee bolts, while tongue J is used for squaring the same on the cross-slide. The manner of using is to feed the front block in until the cross-slide comes against the stop which governs the roughing size, and then reverse the cross-slide and feed the rear tools in until the other stop is reached, thereby controlling the finished size.

Having completed the boring and turning of the discs the three elongated slots are next taken care of by placing discs

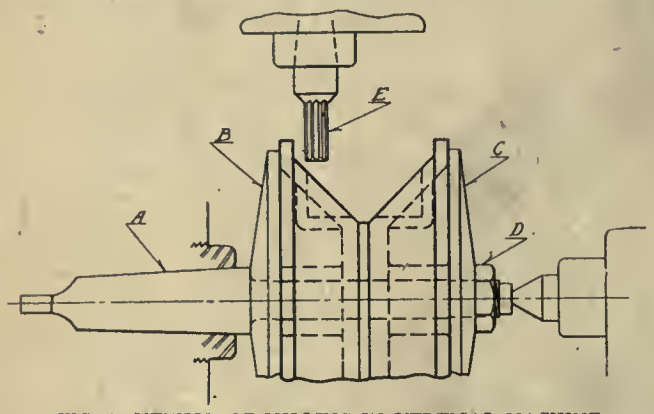

FIG. 4—METHOD OF MILLING IN VERTICAL MACHINE.

on an arbor A Fig. 4. Two large collars B and C are clamped against the outer sides of the work by means of a nut D. The arbor, which has a tapered shank on it, is placed in the dividing head of the milling machine and the tailstock centre of the machine supports the outer end of the arbor. Using an end mill E in a vertical milling machine, and traversing the table longitudinally back and forth with the centre of work under the centre of the cutter, one of the elongated slots is milled, and by indexing the same the three slots are consecutively completed.

This completes the essentials and all that is now necessary is to cut the two discs apart. This is done by placing the work on an arbor, when by using a cutting off tool they are separated. After the discs have been thus cut apart they are replaced on another arbor and a light facing cut is taken across the ends to bring them to correct length.

STANDARDISATION OF TEST PIECES

A report has been issued by the British Engineers Standard Association dealing with the standardisation of test pieces for the notched bar test, now so widely coming into use. The subject of the report has engaged the attention of the association for some considerable time past, and the committee, which has been under the chairmanship of Dr. W. Cawthorne Unwin, has had the benefit of much experimental and research work carried out at the National Physical Laboratory, with funds provided by the Department of Scientific and Industrial Research. The Aeronautical Inspection Department of the Air Ministry has also co-operated, as well as a number of manufacturers, including Sir Robert Hadfield, Bart.

The report commences with a short description of the usual methods adopted for fracturing the test piece, useful notes and data being given of the principal machines used in these tests, viz., Charpy, Izod, Fremont, Amsler and Guillery. The actual form of notch is dealt with, and this is followed by the dimensions recommended for the British standard test pieces and for subsidiary standard test pieces of smaller cross section for use when the former cannot conveniently be obtained. The report concludes with a valuable series of plates illustrating to scale the various test pieces dealt with, the direction and point of impact of the pendulum or falling weight of the testing machine and grips for holding the test pieces. The report can be obtained from the secretary of the B.E.S.A., 28 Victoria Street, S.W.1. Price 30c., post free.

Cutting Production.—Owing to the unsettled conditions of the market, the officials of the Electric Steel and Metals Co., Ltd., of Welland, have deemed it advisable to curtail the operations of their plant for the time being, and on Saturday most of the employees were laid off. Mr. G. C. Mackenzie, the general manager, stated that it was not definitely decided to close the plant altogether, and that the heads of departments, foremen, etc., had been retained in the hope that more favorable conditions will prevail. The Electric Steel & Metals have been in operation in Welland for the past seven years, and during that time have been a valuable asset to the community. They opened up during the war and operated entirely on munition work, until almost the close of hostilities, when they turned their attention to other classes of foundry production.

Mining Tools for Greece.—There is a chance for Canada to sell mining tools and machinery in Greece, according to a statement by Trade Commissioner Clark after a visit to that market. Mr. Clarke sums up the situation as follows: Greek mining for its more progressive and extended exploitation requires principally (a) capital; (b) modern machinery and plant installations; (c) more economical methods in mining operations, and (d) more convenient means and greater facilities of transport. It may be expected that further developments will occur in this industry, whose productive capital already is estimated at at least 69,000,000 drachmas, and Canadian manufacturers of mining tools and machinery should note the existing industry and watch carefully whatever additional progress takes place.

Machining Friction Gear Blank ... riction Co.

Tool Layouts Are Always Interesting, ar... Are Shown Various Examples of Work Performed Acc... to the Practice of the Foster Machine Co., Elk... nd.

By J. H. MOORE

WE have in previous issues shown various tool layouts of interest, and in the present article will illustrate some typical examples of work being performed on Foster turret lathes. These machines are made in Elkhart, Ind., and readers will no doubt remember a description of the machines themselves, which we gave some time ago in our new equipment section.

The examples shown herein deal with the machining of different styles of castings, also the production of parts from the bar stock. The tooling equipment used, as well as a detailed description of the various steps in the operation, are stated and dimensioned drawings of the parts are also shown.

It will be noted that certain reference numbers have been used in the text, and the same numbers apply to both the drawings of the parts and their layout. The surfaces finished on the lathes are indicated by heavy lines, thus making them stand out from the other portion of the view.

In most instances the time of machining is given, this including the time consumed in chucking the work prior to the machining, and in removing it from lathe after completion of operation.

Finishing Friction Gear Blank

Fig. 1 illustrates a cast iron friction gear blank that is finished all over in three operations, the work being performed on a No. 2B universal turret lathe. A layout of the tooling used in the first of these operations is shown at Fig. 2, and the operation is completed in 10.1 minutes, the various steps being taken in the following sequence.

The work is mounted in a three-jawed Barker chuck, which is equipped with a set of corrugated and hardened false jaws that grip the work along the outside of the rough rim. The hole A is rough bored by the cutter mounted in the boring bar, and which is held in the multiple turning head in position 1 of the turret, while the surface B is rough turned by tool K, and surface C is rough

straight bored by the tool L. These tools are held in a special tool holder which is also held in the same fixture mounted at position 1 of the turret.

The end of the boring bar used in the boring of hole A enters a grinding bushing in the chuck before the cut is taken, so that concentricity of the several surfaces is assured. At the same time surfaces D, E and F are rough faced by the tools M, N, and O, respectively, these being held in the square turret shown.

The hole A is again bored by the cutter held in the boring bar which is mounted at position 4 of the multiple turning head. The end of this bushing also extends into the guiding bushing in the chuck while this step of the operation is being performed. The surface B is finish turned by tool K1, and surface C is finish straight bored by tool L1, these tools being held in a special holder that is also mounted at position 4 of the turret. At the same time surface F is finish faced by tool P, which is held in the rear tool holder shown.

The gear blank is now removed from the chuck, and the machine as used is shown at Figs. 3, 4 and 5. The arrangement of the tools in these illustrations differs slightly from that shown at Fig. 2 in which the tool used in finish facing surface F is mounted in a rear tool holder, while the other views show the tool mounted in the square turret. Figs. 3 and 4 show the front of the machine, while Fig. 5 shows the machine looking from the top. All these illustrations depict clearly the tooling equipment as employed.

The equipment used in the second operation is shown at Fig. 6. The operation in this case is completed in 9.1 minutes, the sequence of the steps being as follows: The work is first secured in a three-jawed Barker chuck equipped with a set of jaws that hold the work by bearing on the previously finished surface C. The surfaces H and I are next rough turned by tools Q and R. These tools are mounted in the multiple turning at position 1 of the turret. This fixture is provided with a pilot that extends into a guiding bushing in the chuck while the cuts are being taken, thus ensuring that the surfaces machined will be concentric with hole A.

At the same time surface G is rough faced by tool S, which is mounted in the square turret. The surfaces H and I are next finish turned respectively by tools Q1 and R1, these being held in a special tool holder in the multiple turning head, mounted in position 3 of the turret. The hole A is finish bored by the cutter held in boring bar T, which is mounted in the same turning head. At the same time surface J is rough faced by tool S, and finish faced by tool U. Both these tools are held in the square turret. The hole A is now reamed by the expansion reamer held in position 5 of the turret. After this the work is removed from the lathe.

The photograph Fig. 8 was taken at the end of the third step of the series, and the tooling used is shown at Fig. 7. This operation is performed in 2.4 minutes, and the successive steps are as follows:

Third Operation

The work is secured in an air operated draw back adapter, which is inserted in the hole A. The surface C is rough taper bored by tool V, which is held in the square turret, this tool being used in conjunction with the taper attachment on rear of machine. Surface C is finish taper bored by a special tool held in the multiple turning head in position 1 of the turret. A pilot on the operating rod of the adapter enters a guiding hole in the multiple tur-

ing head as the head is advanced for this step, thus locating the tool so that surface C is bored concentric with hole A. After this the finished work is removed from the machine. These three operations are completed in a total time of 21.6 minutes.

Machining Friction Cones

The friction cone, used in connection with the gear blank just described, is illustrated at Fig. 9. This part is made of cast iron, and two chuckings are required in finishing it, both of which are performed on the No. 2B machines, in the fast time of 9.7 minutes. Fig. 10 shows a layout of the tooling used in the first operation, this being completed in 5.3 minutes. The steps taken are as follows:

The work is placed in a three-jawed Barker wrenchless chuck equipped with corrugated and hardened false jaws that grip the work along the rough surface of the rim. Hole A is now rough bored by the cutter held in the boring bar mounted at position 1 of the turret, this being provided with a pilot that extends into a guiding bushing in the chuck while the cut is being taken.

At the same time surface B is rough faced by tool G, which is mounted in the square turret, and surface C is rough faced by the tool H, which is

Report on Coarse and Fine Threads—Part II.

This Portion Concludes the Article from Last Issue, and Specifies the Gauges in Detail—It Also Supplies Tables of Tolerances for Them, and Includes Specifications for Screw Thread Productions.

THE general subject of gauging screws is too extensive to be fully covered in this report. Reference is made, however, to bulletins published by the Bureau of Standards covering various inspection methods, including the standard ring and plug gauges, and the optical projection method of gauge inspection; also, to an article in the "Journal" of American Society of Mechanical Engineers of February, 1919, with reference to the use of the projection lantern for gauging work.

Inasmuch as the threaded plug and ring limit gauge is the most universally used scheme of gauging, and one that has been brought to the highest state of refinement, there is set forth herein what is considered the best practice used in the production and use of such gauges. It is understood, however, that it is not the intention of this commission to confine manufacturers to any particular method of gauging, as that would tend to hinder progress.

It has been the practice of many manufacturers, including Government shops, to work with "Go" gauges only and to depend upon the judgment of a good workman to keep within proper limits by the amount of "shake" or difference between the work and the gauge. With a highly skilled and trained force working on but one kind of work and also referring the working gauge to but one master gauge, a fair degree of interchangeability can be maintained under these conditions.

In the recent military preparations the Government required munitions in such vast quantities and in such a short period of time that this method of insuring interchangeability failed, and a method of gauging had to be established which did not rely entirely upon the skill and judgment of the workmen or inspectors. One reason for the necessity of a complete gauging system was that it was not possible to obtain a sufficient number of skilled workmen or inspectors. Furthermore, one master gauge could not be used all over the country and consequently discrepancies in measurement between different shops had to be guarded against by the use of properly tested standards and by approved methods of measuring.

It is believed that the experience gained by manufacturers producing war material will result in a much more extensive use of gauges than was ever thought practicable during pre-war times. The gauge specifications which are given herein cover the manufacture, use and application of a system of gauging which has been thoroughly demonstrated in the execution of war contracts as being adequate for the production in large quantities of strictly interchangeable screw-thread product. It is not the intention of this report to limit manufacturers to any particular methods of test in checking either the manufactured product or in measuring gauges, for the reason that any specification which would tend to limit the development of new and improved methods of measuring would be very undesirable. However, when the ordinary forms of thread gauges are used, the specifications given herein will apply.

Gauges and Methods of Test

The specifications for gauges given herein are built upon the following fundamental assumptions:

Approved limit master gauges do not reduce the net working tolerance. Permissible errors in angle of thread specified for "Go" gauges tend to reduce the net working tolerance, while similar permissible errors on the "Not Go" gauge tend to increase the net working tolerance. These two factors, therefore, balance each other. Permissible lead errors specified for the "Go" gauge reduce the net working tolerance, while permissible lead errors on the "Not Go" gauge tend to increase the net working tolerance. In order to realize the full net working tolerance, the permissible diametrical variation specified for both "Go" and "Not Go" gauges (gauge increment) is placed outside of the net tolerance limits. The extreme tolerance equals the net tolerance plus gauge increment. The "Go" gauge should check simultaneously all elements of the thread (all diameters, lead, angle, etc.). The "Not Go" gauge should check separately the elements of the thread.

The following general specifications refer in particular to gauging systems which have been found satisfactory by the Army and Navy for the production of interchangeable parts as specified under the subject of "Classification and Tolerances." These specifications are included for the use of manufacturers where definite information is lacking. They are not to be considered mandatory.

Thread gauges may be included in one of four classes, namely: standard master gauges, limit master gauges, inspection gauges, and working gauges.

The standard master gauge is a threaded plug representing as exactly as possible all physical dimensions of the nominal or basic size of the threaded component. In order that the standard master gauge be authentic, the deviations of this gauge from the exact standard should be ascertained by the National Bureau of Standards and the gauge should be used with knowledge of these deviations or corrections.

Limit master gauges are for reference only. They represent the extreme upper and lower tolerance limits allowed on the dimensions of the part being produced. They are often of the same design as inspection gauges. In many cases, however, the design of the master gauge is that of a check which can be used to verify the inspection or working gauge.

Inspection gauges are for the use of the purchaser in accepting the product. They are generally of the same design as the working gauges and the dimensions are such that they represent nearly the net tolerance limits on the parts being produced. Inasmuch as a certain amount of wear must be provided on an inspection gauge, it can not represent the net tolerance limit until it is worn to master gauge size.

Working gauges are those used by a manufacturer to check the parts produced as they are machined. It is recommended that the working gauges be made to represent limits considerably inside of the net limits in order that sufficient wear will be provided for the working gauges, and in order that the product accepted by the working gauges will be accepted by the inspection gauges.

The following list enumerates the inspection and working gauges required for producing strictly interchangeable screws as specified for national coarse threads, national fine threads, or other straight threads.

(a) A maximum or "Go" ring thread gauge, preferably adjustable, having the required pitch diameter and minor diameter. The major diameter may be cleared to facilitate grinding and lapping.

(b) A minimum or "Not Go" ring thread gauge, preferably adjustable, to check only the pitch diameter of the threaded work.

(c) A maximum or "Go" plain ring gauge to check the major diameter of the threaded work.

(d) A minimum or "Not Go" snap gauge to check the major diameter of the threaded work.

The following list enumerates the inspection and working gauges required for producing strictly interchangeable nuts, as specified for national coarse threads, national fine threads, or other straight threads.

(a) A minimum or "Go" thread plug gauge of the required pitch diameter and major diameter. The minor diameter of the thread plug gauge may be cleared to facilitate grinding and lapping.

(b) A maximum or "Not Go" thread plug gauge to check only the pitch diameter of the threaded work.

(c) A "Go" plain plug gauge to check the minor diameter of the threaded work.

(d) A "Not Go" plain plug gauge to

check the minor diameter of the threaded work.

The following list enumerates the limit master gauges required for the verification of the working or inspection gauges as previously listed for verifying the screw.

(a) A set plug or check for the maximum "Go" thread ring gauge, having the same dimensions as the largest permissible screw.

(b) A set plug or check for the minimum or "Not Go" thread ring gauge having the same dimensions as the smallest permissible screw.

(c) A maximum plain plug for checking the minor diameter of both the "Go" and "Not Go" inspection thread ring gauge.

The following list enumerates the limit master gauges required for the verification of the working or inspection gauges as previously listed for verifying the nut.

(a) A minimum or "Go" threaded plug to be used as a reference for comparative measurements, corresponding to the basic dimension, or standard master gauge.

(b) A maximum or "Not Go" threaded plug to be used as a reference for comparative measurements, corresponding to the largest permissible threaded hole.

(c) A minimum plain ring gauge to check the major diameter of the "Go" and "Not Go" master threaded plug unless suitable measuring facilities are available for this purpose.

Gauges may be made of a good grade of machinery steel pack-hardened, or of straight carbon steel of not less than 1 per cent. carbon; or preferably of an oil hardening steel of approximately 1.10 per cent. carbon and 1.40 per cent. chromium.

Handles should be made of a good grade of machinery steel plainly marked to identify the gauge.

The following specifications will be helpful in the design and construction of gauges used for producing threaded work.

All plain plug gauges should be single-ended. Plain plug gauges of 2 in. and less in diameter should be made with a plug inserted in the handle and fastened thereto by means of a pin. Plain plug gauges of more than 2 in. in diameter should have the gauging blank so made as to be reversible. This can be accomplished by having a finished hole in the gauge blank fitting a shouldered projection on the end of the handle, the gauge blank being held on with a nut.

The "Go" plain plug gauge should be noticeably longer than the "Not Go" plain plug gauge, or some distinguishing feature in the design of the handle should be used to serve as a ready means of identification, such as a chamfer on the handle of the "Go" gauge.

Both the "Go" and "Not Go" gauges should have their outside diameters knurled if made circular.

The "Go" gauge should have a decided chamfer in order to provide a ready means of identification for distinguishing the "Go" from the "Not Go" gauge.

Snap gauges may be either adjustable or non-adjustable. It is recommended that all snap gauges up to and including ⅛ in. be of the built-up type. For larger snap gauges, forged blanks, flat plate stock or other suitable construction may be used.

Sufficient clearance beyond the mouth of the gauge should be provided to permit the gauging of cylindrical work.

Snap gauges for measuring lengths and diameters may have one gauging dimension only, or may have a maximum and minimum gauging dimension, both on one end, or maximum and minimum gauging dimensions on opposite ends of the gauge. When the maximum and minimum gauging dimensions

TABLE IX. SUGGESTED MANUFACTURING TOLERANCES FOR INSPECTION GAGES FOR LOOSE FIT AND MEDIUM FIT WORK

Number of Threads per Inch	Allowable Variation in Lead Between Any Two Threads Not Farther Apart than Length of Engagement	Allowable Variation in One-half Angle of Thread Gages	Allowable Tolerances on Diameters of Minimum Thread Gages	Allowable Tolerances on Diameters of Maximum Thread Gages
4 to 6	±0.0006	±0° 5′	+0.0006 +0.0015	—0.0006 —0.0015
7 to 10	±0.0005	±0° 10′	+0.0004 +0.0010	—0.0004 —0.0010
11 to 18	±0.0004	±0° 15′	+0.0004 +0.0008	—0.0004 —0.0008
20 to 28	±0.0003	±0° 20′	+0.0003 +0.0006	—0.0003 —0.0006
30 to 40	±0.0002	±0° 30′	+0.0002 +0.0005	—0.0002 —0.0005
44 to 80	±0.0002	±0° 45′	+0.0002 +0.0004	—0.0002 —0.0004

are placed on opposite ends of the gauge, the maximum or "Go" end of the the corners of the gauge on the "Go" end decidedly chamfered.

All plug thread gauges should be single-ended. Thread plug gauges 2 in. and less in diameter should be made with a plug inserted in a handle and fastened thereto by means of a pin.

Plug gauges of more than 2 in. in diameter, unless otherwise specified. should have the gauging blank so made as to be reversible. This can be accomplished by having the finished hole in the gauge blank fitting a shouldered projection on the end of the handle, the gauge blank being keyed on and held with a nut.

"Not Go" thread plug gauges should be noticeably shorter than the "Go" thread plug gauges, in order to provide a ready means of identification, or the handle of the "Go" gauge should be chamfered.

End threads on plug thread gauges should not be chamfered, but the first handle of the "Go" gauge should be flattened to avoid a feather edge.

Inspection and working thread plug gauges should be provided with dirt grooves which extend into the gauge for a depth of from one to four threads.

The length of thread parallel to the axis of the gauge should, for all standard "Go" thread plug gauges, be at least as much as the quantity expressed in the following formula:

Where
L = (1.5) D
L = Length of thread
D = Basic major diameter of thread.

For threaded work of shorter length of engagement than (1.5) D, the length of thread on the "Go" gauge may be correspondingly shorter.

"Not Go" thread gauge for pitch diameter only: All "Not Go" thread plug gauges should be made to check the pitch diameter only. This necessitates removal of the crest of the thread so that the dimension of the major diameter is never greater than that specified for the "Go" gauge, and also removing the portion of the thread at the root of the standard thread form.

All ring thread gauges should be made adjustable.

The "Go" gauge should be distinguished from the "Not Go" gauge by having a decided chamfer and both gauges are to have their outside diameter knurled if made circular.

The end threads on ring thread gauges should not be chamfered but the first half turn of the end thread should be flattened to avoid a feather edge.

The length of thread parallel to the axis of the gauge should, for all standard "Go" ring thread gauges, be at least as great as the quantity determined in the formula perviously given. For threaded work of shorter length of engagement than (1.5) D, the length of thread on the "Go" gauge may be correspondingly shorter.

"Not Go" ring thread gauges should be made to check the pitch diameter only. This necessitates removal of the crest of the thread so that the dimension of the minor diameter is never less than that specified for the maximum, or "Go" gauge and also removing the portion of the thread at the root of the standard form. There are specified herein for use in the production of national coarse threads and national fine threads, and for other straight threads, several tables of gauge manufacturing tolerances.

Table VII will be found practicable for all plain plug, ring and snap gauges used in connection with a measurement of screw thread diameters. In addition to the master gauge tolerances, suggested tolerances for inspection and working gauges are also given in Table VII.

Table VIII will be found practicable for both standard and limit master thread gauges for thread work designed in accordance with the manufacturing tolerances for Class I, loose fit and Class II, medium fit, made to Tables III, IV and V.

Table IX contains suggested manufacturing tolerances for inspection thread gauges with a small allowance for wear for use in quantity production of Class I, loose fit, and Class II, medium fit thread work, made to Tables III, IV and V.

Table X contains suggested manufacturing tolerances for working thread gauges with a small allowance for wear for use in quantity production of Class I, loose fit, and Class II, medium fit thread work, made to Tables III, IV and V.

Table XI contains the tolerances suggested for both standard and limit master thread gauges for work designed in accordance with manufacturing tolerances for Class III, close fit thread work, made to Table VI. As the component tolerances for this class are relatively small, it is believed that the working gauges will be required to be held within the gauge tolerances shown in Table XI.

For plain plug gauges, plain ring gauges, and plain snap gauges required for measuring diameters of screw thread work, the gauge tolerances specified in Tables VIII, IX, X and XI should be used. Attention is called to the fact that the tolerances on thread diameters vary in accordance with the number of threads per inch on the screw or nut being manufactured. In manufacturing a plain plug, ring or snap gauge, in the absence of information as to the number of threads per inch of the screw to be made, or for gauge dimensions other than thread diameters, the tolerances for plain gauges given in Table VII may be used.

The tolerances on lead are specified as an allowable variation between any two threads not farther apart than the length of thread engagement as determined by the following formula:

Where
L = (1.5) D
L = Length of thread engagement
D = Basic major diameter of thread.

The tolerances on angle of thread as specified herein for the various pitches are tolerances on one-half of the included angle. This insures that the bisector of the included angle will be perpendicular to the axis of the thread within proper limits. The equivalent deviation from the true thread form caused by such irregularities as convex or concave sides of thread, rounded crests, or slight projections on the thread form, should not exceed the tolerances allowable on angle of thread.

The tolerances given for thread diameters in Tables VIII, IX, X and XI. are applied in such a manner that the tolerances permitted on the inspection and working gauges occupy part of the extreme tolerance. This insures that all work passed by the gauges will be within the tolerance limits specified on the part drawing as represented by the limit master gauges. The tolerances given also per-

mit the classification and selection of gages so that if a gage is not suitable for a master gage it may be classified and used as an inspection or working gage provided that the errors do not pass outside of the net tolerance limits. The application of the tolerances on diameters of thread gages is exactly the same as explained herein for plain gages. For an example of this application see Table XII.

Typical Specifications

Material: The material used shall be cold-drawn bessemer steel automatic screw stock.

Composition:

Carbon, 0.08 to 0.16 per cent.
Manganese, 0.50 to 0.80 per cent.
Phosphorus, 0.09 to 0.13 per cent.
Sulphur, 0.075 to 0.13 per cent.

Method of manufacture: Bolts and nuts may be either rolled, milled, or machine cut, so long as they meet the specifications herein provided. Bolts and nuts to be left soft.

Workmanship: All bolts and nuts must be of good workmanship and free from all defects which may affect their serviceability.

Finish: All bolts and nuts to be semi-finished; that is, the bodies to be machined, under side of head and nut faced, upper face of head and nut to be chamfered at an angle of 30 deg., leaving a circle equal in diameter to the width of the nut.

Form of Thread: The form of thread shall be the "national form," as specified herein, and formerly known as the United States standard or Sellers thread.

Thread Series: The pitches and diameters shall be as specified in Table I, herein, and known as the National coarse thread series.

Class of Fit: Class II-A, medium fit (regular).

Dimensions: Nominal size: ½ inch. Number of threads per inch: 13. Length under head: 3±0.05 inches. Minimum length of usable thread: 1 inch. Diameters: (Specified in Table XI of complete report).

Tolerances and Allowances: See Table IV.

Nuts: Form: Hexagonal. Thickness: ½±0.01 inch. Short diameter (across flats): ⅞±0.01 inch.

Heads: Form: Hexagonal. Thickness: 7-16±0.01 inch. Short diameter (across flats): ⅞±0.01 inch.

Gages: The gages used shall be such as to insure that the product falls within the tolerances as specified herein for Class II, medium fit (regular):

The following gages are suggested and will be used by the purchaser:

For the Screw:

A maximum or "Go" ring thread gage.

A minimum or "Not Go" ring thread gage to check only the pitch diameter of the thread.

A maximum or "Go" plain ring to check the major diameter of the thread.

A minimum or "Not Go" snap gage to check the major diameter of the thread.

For the Nut:

A minimum "Go" thread plug gage.

A maximum or "Not Go" thread plug gage to check only the pitch diameter.

A "Go" plain plug gage to check the minor diameter.

A "Not Go" plain plug gage to check the minor diameter of the thread.

Inspection and Test: Screws and nuts shall be inspected and tested as follows:

At least three bolts and nuts shall be taken at random from each lot of 100, or fraction thereof, and carefully tested. If the errors in dimensions of the screws or nuts tested exceed the tolerance specified for this class, the lot represented by these samples shall be rejected.

Delivery: Unless otherwise specified the assembled bolts and nuts are to be delivered in substantial wooden containers, properly marked, and each containing 100 pounds.

The commission, in formulating this progress report, has acted largely in the capacity of a judiciary, basing its decisions upon evidence received from authorities on screw-thread subjects and upon the conclusions drawn by other organizations having to do with standardization of screw threads. In addition, the various subjects dealt with have been considered with a knowledge of present manufacturing conditions and with anticipation of further development in the production of screw-thread products. Above all, it is the intention of the commission to facilitate and promote progress in manufacture.

In the time provided the commission has devoted its attention to the standardization of only those threads, sizes, types and systems which are of paramount importance by reason of their extensive use and utility. There remains much to be accomplished along the lines of standardization of special but important threads, and of maintaining progress in our standardization work in keeping with the developments of manufacturing conditions.

TABLE XII. TOLERANCES AND LIMITS ON MAXIMUM AND MINIMUM MASTER, INSPECTION AND WORKING GAGES FOR SHAFT AND HOLE

Work to be gaged:

Hole,	1.250 + 0.004	1.254	max.
	— 0.000	1.250	min.
Shaft,	1.248 + 0.000	1.248	max.
	— 0.004	1.244	min.

Gages for hole:

Maximum Gages

	Dimension of Part	Gage Tolerances	Gage Limits
Limit master gage	1.254	—0.0000	1.2540
		—0.0003	1.2537
Inspection gage	1.254	—0.0004	1.2536
		—0.0007	1.2533
Working gage	1.254	—0.0008	1.2532
		—0.0013	1.2527
Minimum Gages			
Limit master gage	1.250	+0.0000	1.2500
		+0.0003	1.2503
Inspection gage	1.250	+0.0004	1.2504
		+0.0007	1.2507
Working gage	1.250	+0.0008	1.2508
		+0.0013	1.2513

Gages for shaft:

Maximum Gages			
Limit master gage	1.248	—0.0000	1.2480
		—0.0003	1.2477
Inspection gage	1.248	—0.0004	1.2476
		—0.0007	1.2473
Working gage	1.248	—0.0008	1.2472
		—0.0013	1.2467
Minimum Gages			
Limit master gage	1.244	+0.0000	1.2440
		+0.0003	1.2443
Inspection gage	1.244	+0.0004	1.2444
		+0.0007	1.2447
Working gage	1.244	+0.0008	1.2448
		+0.0013	1.2453

By comparison of the above figures, it will be seen that it is not possible for the master, inspection or working gage dimensions to overlap.

According to an estimate of the mining bureau of the Department of Agriculture and Commerce at Tokyo, based mainly on coal veins over 2 ft. thick, and generally lying not more than 2,000 feet below drainage level, the available coal deposits of Japan amount to about 822,000,000 metric tons of 2,204 pounds. In addition, it is judged that approximately 2,940,000,000 metric tons, which lie at greater depths, can be mined if highly efficient methods are used. It is also surmised that the concealed and undetermined deposits of coal may possibly amount to 5,030,000,000 metric tons.

Change in Name.—The Machine & Stamping Co., Ltd., 1209 King Street West, Toronto, Ont., changed its name on October 1 to the Russell Gear & Machine Co., Ltd., without changing the management.

WELDING AND CUTTING

Lessons on the A. B. C. of Good Welding

A Knowledge of the Torch You Are Using is Absolutely Essential if You Feel You May Require to Make Some Repair to It.

By W. B. PERDUE *

THE ordinary individual, who has no ambition other than to work in a shop under the direction of a competent foreman, need not worry about the construction of his torch. In fact, the less tampering he does with it the better he will get along. Simple as they may seem, torches are instruments of precision. In the best regulated welding shops they are treated as such; their repair is left to experts; those in readiness for operation are ranged in good order; kept free from dirt and grime; in good preservation and working order, as all tools of precision deserve to be treated.

The operator who feels that he may at some time be required to make emergency or other repairs should see to it that he has expert knowledge and the thorough understanding that will enable him to get directly at the seat of trouble and remedy it without delay.

Necessary Principles

There are certain fundamental principles involved in the construction and use of any tool. The expert is the person whose knowledge of these principles enables him, by examination, to locate the source of trouble, and to determine what corrective measures may be required to produce or restore normal working conditions.

We will now discuss at length the principles upon which successful operation of oxy-acetylene equipment depends, giving credit where due to the originators and inventors of new ideas and for quotations which follow to Messrs. Granjon & Rosenberg of Paris, the pioneer oxy-acetylene experts.

1. "The chief difficulty to be overcome is to obtain the necessary stability of flame; (a) The velocity of propagation (the speed with which the flame will burn) of the flame is about 330 feet per second; (b) It is therefore necessary, in order to avoid the striking back of the flame, that the velocity of the mixture at the exit should be of the same value, or at least such that it constantly prevents the return of the flame to the interior."

The theoretical calculations of the author proved the velocity of propagation given above to be about one-third more than it would be in a stirred and stabilized mixture. It then occurred to him that in maintaining this excessive and unnecessary speed the temperature of the flame was actually diminished, to the extent that a great deal less effective heat energy was developed than resulted from the complete combustion within the flame of exactly proper proportions of gases travelling at much lower velocities.

No matter how well constructed are the regulators which govern the flow of gases to the torch, it is necessary to employ some means within the torch to prevent the passage through the flame of alternate excesses of oxygen and acetylene.

Changes in Flame

These changes may be so slight as to cause no visible change of the flame, but careful examination of the weld will reveal adequate proof of the fluctuations which take place. The amount of gas wasted is considerably more than might be imagined, since the passage through the flame of even a slight excess of either gas very materially lowers its temperature and efficiency. To avoid flashing of the torch it is necessary that the velocity of the flow be greater than the propagation of the flame at the time when it is intermittently "lean"; that is, at the time when the amount of acetylene is lowest and an excess of oxygen predominates.

It is a very significant fact that in our large power plants where the steam

CUTTING AN INGOT FOR STEAMSHIP CRANKSHAFT.

*Mr. Perdue is in charge of welding instruction at Heald's Engineering School, San Francisco. He wishes to state that owing to sickness he has been unable to answer queries, but is again able to do so.

pressure seldom varies more than a pound in 250 no well-informed engineer would consider the installation of an engine without a governor. Here economy is the principal factor. With gas pressures of say ten pounds the fluctuation of a mere fraction of an ounce would be proportionately equal. Here the soundness of the weld and the possibility of endangering life and property through its failure must be considered.

The Modern Welder

Is it any wonder then that the modern, progressive welder demands to see the stabilizing chamber in a torch before buying, and that he is favored with more work than he can handle, while his competitor with antiquated equipment blames hard luck for the failures of his welds and his lack of patronage.

For his success in developing the stirring and stabilizing chamber in torches the author is indebted in a measure to Remond J. Tobin, of Richmond, Calif., the inventor of the Tobin Patent Adjustable Welding Head, which was used with such great success in torpedo boat construction during the recent war.

"The intimate mixture of gases should be perfectly accomplished before their escape from the blowpipe. . . . In some torches there is an energetic mixing of the two gases, but the contact is not made molecule to molecule, and stream lines of oxygen or acetylene can escape at the nozzle without being mixed."

Inasmuch as oxygen can be used without limits of pressure, oxy-acetylene torches are divided according to pressure of acetylene required into three principal classes:

(1) Equal pressure type — for high pressure acetylene.

(2) Positive pressure type — for medium pressure acetylene.

(3) Injector type — for low pressure acetylene.

Low pressure acetylene generators can be used only with injector type torches. Medium pressure generators have a range up to twelve pounds and can be used with the smaller tips furnished with equal pressure torches or with tips of any size on positive pressure torches.

Change of Torches

Inasmuch as all torches designed by the author can be changed to any of the foregoing types by substitution of another mixer, and as he has nothing to gain by extolling the merits of any particular type, he feels competent to discuss the various types from a standpoint of merit. The patents issued to most torch producing concerns limit them to one particular type of construction. It is extremely interesting to observe salesmen inviting the attention of prospective customers to the "low pressures" with which their torches operate, or to the "extremely small orifices" which are supposed to result in economical operation.

Now any reasoning person knows that with a small orifice the greater the required pressure to force therethrough a fixed or definite amount of gas and vice versa. It is also well known that it requires a certain definite amount of fuel gas to generate a certain definite amount of heat, therefore, the principal points of merit in all classes of gas burning devices are those outlined in requirements 1 and 2.

"Blowpipes for high-pressure acetylene were first to be constructed. They were designed for using dissolved acetylene, and are practically used only for that purpose now."

It is a lamentable fact that many makers of this type of equipment advertise that their torches will give satisfaction with generator pressures. Conditions over which the manufacturer has no control, such as the length and size of hose, piping, and connectors, are such that the use of printed pressure tables is quite misleading; therefore, the author invariably advises operators to set the regulator at that pressure which causes the acetylene flame to cease giving off smoke before turning on the oxygen. If desired, these pressures may be adjusted at the regulators for the larger tips and necessary adjustments for smaller sizes made by means of the valves on the torch.

Any intelligent workman, familiar with torch construction, can produce an equal pressure torch. Where means are not provided for stirring and stabilizing the flow of gases such torches are producers of inferior welds, are expensive in operation, and should not be used for professional welding work.

This idea is best illustrated by comparing the effect produced by a clear stream flowing at the same velocity into a muddy river. Miles below their junction can be discerned the clear water still flowing independently on.

Now let us imagine the speed of the clear stream to be increased. This produces an eddying effect which tends in some measure to commingle it with the other water. It is possible, however, to increase this speed to a point where the tendency to mix with the muddy water is lessened. Thus we learn from facts known since childhood, that extremely low pressures of acetylene, which require correspondingly high pressures of oxygen, as well as those pressures of acetylene which are equal to the oxygen, are not, without special stirring devices, conducive to efficiency.

Effects of Streams

Next let us imagine the effect of passing these streams through a conical expansion (diamond shaped) chamber such as is used in many torches. The tendency to commingle will be slightly increased, but hardly enough to be noticeable. These tests, made with colored gases and liquids under every possible variation of pressures and conditions, and the use of specially sensitized plates to determine the efficiency of the mixtures produced, have proved the conical chamber mixing theory to be impractical.

Lastly let us imagine these streams driven through a broken conduit of shape similar to the stabilizing chamber of a modern torch. Here they are completely commingled. Furthermore, little if any convulsive effect is imparted to the stream flowing out and away from such chamber. Thus is secured the mixture and stability required to produce perfect combustion of gaseous mixtures.

In low pressure injector type torches the acetylene, under slight pressure, enters a suction chamber from whence it is aspirated by the suction of a stream of oxygen under higher pressure. This is accomplished by means of a device known as the Giffard injector, which operates by intermittently creating a partial vacuum, drawing in the acetylene, expelling it, and repeating the process.

Torches of the positive pressure type, when equipped with stabilizing chamber of proper construction, combine the advantages of the other two types, and can be used for any and all varieties of work.

3. "The torch must be so constructed that the delivery of the proper proportions of gases to the nozzle will not be affected by its becoming heated."

Here an examination of the torch prior to purchase to determine what means, if any, have been taken to insulate the mixing device and the stirred gases from the heat is the only precaution that can be recommended. The construction of tip and mixing device of one piece of metal certainly simplifies the construction of the torch, and enables it to be sold more cheaply. It often happens that the heating of the tip of such torches causes a leakage of oxygen into the acetylene chamber, producing a condition which invariably causes a tendency to flash.

As an emergency measure, recommended only when better equipment cannot be procured, the acetylene pressure may be increased, and the oxygen orifice drilled or reamed to such size as requires a slightly lower oxygen pressure than that of the acetylene.

Weight of Importance

The weight of a torch is a matter of some importance. The good mechanic likes a tool which is light and "feels good in the hand." It goes without saying that more and better work will be done with torches which "fit the hand" and are light and easy to handle than with those which are built without thought of convenience in handling.

Metal to metal seats on tips and other movable parts should be kept clean and free from grit. Tips should be kept clean both inside and out, since any accumulation on the outside of the tip causes it to become heated more quickly than a clean tip. It is still more important that the orifice of the nozzle be kept free from incrustations and obstructions. This must not be done by means of wires or broaches inserted from the flame end, or by rubbing the face of the tip on the bricks of the welding table. In old fashioned non-stabilizing injector type torches any widening of the nozzle causes a derangement of the torch. Such types may be cleaned only by means of

(Continued on page 61)

DEVELOPMENTS IN SHOP EQUIPMENT

NEW OPEN-SIDE PLANER

The L. & P. Manufacturing Co., Niagara Falls, Ont., have placed on the market both open-side planers and the double column planer shown in illustration. The beds of these machines are of closely ribbed type fully enclosed between the ways. The fourteen-foot machines have three oil wells provided to each of the vees. The worm bearings are cast solid in the bed with reservoirs to maintain oil above the centre of the drive. Outside housing for thrust bearing and reduction gears are cast solid with the bed.

The housings of the double column planer as shown in illustration are of heavy box pattern, provided with clamping screws for holding in working position to both housings.

The planers are of double deck box type, having ports in sides for removal of chips, stake holes being drilled through top deck only. This prevents chips dropping into driving mechanism. Three tee slots are provided and four rows of 1-inch stake holes spaced twelve inches apart each way.

The columns are of heavy box pattern and are well ribbed and securely fastened to the bed.

Four tool heads are furnished on the two column planer, two on the open-side planer. Each of these heads are of standard heavy swivel type provided with parallel gibs with set screw take-ups. The feed screws are fitted with micrometer collars.

The parallel drive is obtained by forged steel worm and cast iron machine cut rack, the worm lying at such an angle that thrust is parallel to the ways.

All shaft bearings are split bronze lined boxes, excepting those supporting the worm, the latter being solid. The drive thrust bearings are readily adjustable, and consist of a number of steel, bronze and fibre disks, having radial oil grooves across their faces. They run in an oil well located outside the bed. Reversing thrust bearings are similar but are located inside the worm oil well.

Worm bearings and oil reservoir are piped to filler connection outside of bed, and thus platen need not be removed for refilling. The balance of drive bearings, being outside of bed, are accessible at all times.

The motor is connected by flexible coupling to driving pinion shaft on left hand side behind planer close to bed.

The reduction gears consist of one pair of wide face spur gears fully enclosed, arranged to run in oil, the drive pinion being provided with an outboard bearing.

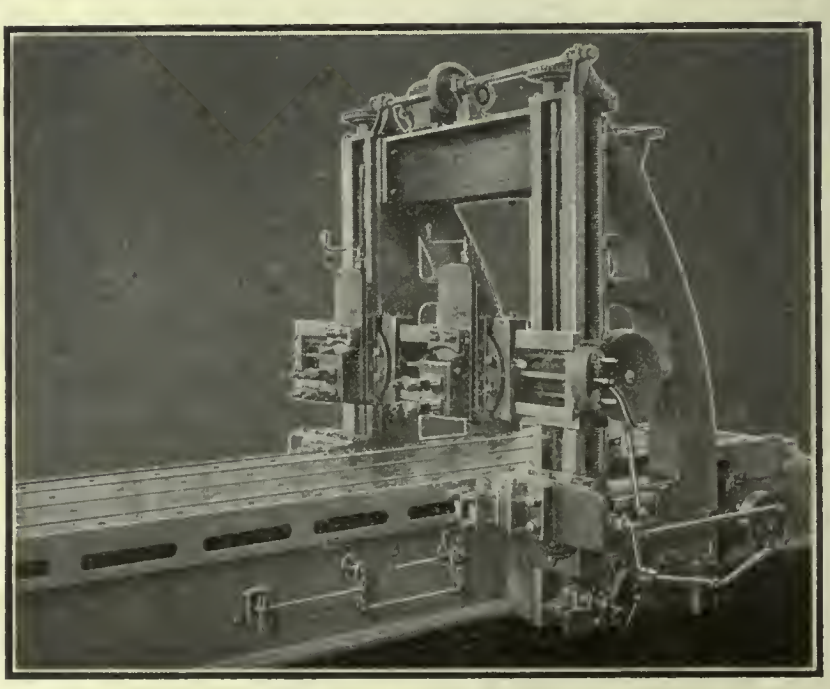
Following are the specifications for the double column machine. Planer width 48 inches, width between housings 50 inches, length of table over all 15 feet 6 inches, length of bed over all 23 feet 4 inches. The length of down feed of head or cross rail is 9 inches, and the minimum distance centre of tool blocks is 19 inches. The width over gear belt is 8 feet 1½ inches, and the height over gears 8 feet 10 inches.

The other specifications herewith on the open-side type are self-explanatory, and these machines are made in both the belt and motor types.

Planer width 48 inches, length of table over all 15 feet 6 inches, length of bed over all 23 feet 4 inches, length of down feed of head on cross rail 9 inches, floor space length, including table travel 32 feet, planer height 48 inches, maximum height under rail 50 inches, width of table 44 inches, horse-power required 15 to 25. The drive motor used is a 25 horse-power reversible variable speed planer motor and runs from 250 to 100 r.p.m. The cross rail motor is a 2 horse-power constant speed motor running at 1,150 r.p.m.

ROTATABLE COAL HOPPER

Firemen on big locomotives find promise of lightened work in the rotatable coal hopper that has been invented for engine tenders. This invention is so planned that the coal is kept handy at the firing deck, making it an easy matter for the firemen to reach the coal without shoveling from the rear of the tender or using power apparatus. This special hopper is in the form of a great segmental tub, or drum, having a diameter that is the approximate width of the tender. This drum is inclined toward the firing deck; it is so mounted on a ball-bearing centre plate as to turn readily. In its outer wall are openings, one for each segment, through which the coal falls by gravity. As soon as the coal is emptied from the segment, the brake that controls the drum is released. Naturally the greater weight above the centre of the drum makes it rotate, bringing the next loaded segment into position.

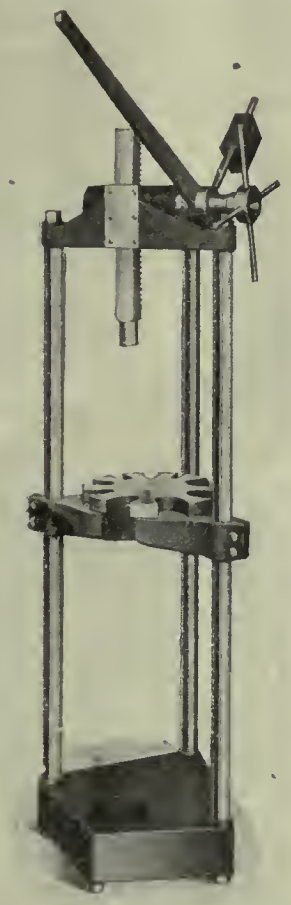


GENERAL VIEW OF THE DOUBLE COLUMN MOTOR DRIVEN PLANER.

NEW ARBOR PRESS

The National Engineering Co., Ltd., Sarnia, Canada, have placed on the market a new arbor press, an illustration of which is shown.

Instead of using the old "goose-neck," a "three-point" construction with a direct strain is adopted. The machine, neatly



GENERAL VIEW OF ARBOR PRESS.

finished, is of light weight and occupies the small floor space of 20 inches.

Some of the features of superiority in this three-ton press are as follows: It has a 36-inch range, which makes it a very useful tool in garages for removing gears, etc. It also has an adjustable table with nine openings on the dial, and the ratchet wherein the strain is placed on all the teeth instead of one tooth. The machine has a capacity of 16-inch diameter. The A. R. Williams Machinery Co. are selling agents for the "NECO" line.

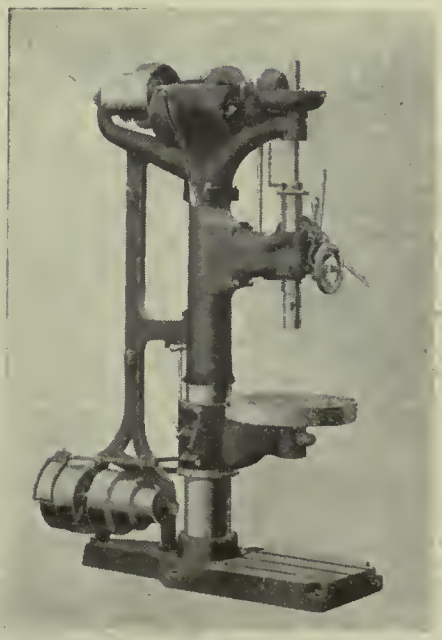
DRILL PRESS

The Sibley Machine Co., South Bend, Ind., U.S.A., have placed on the market a new stationary head drilling machine with positive geared feed, back gears, etc. It is modelled very much after the style of their sliding drill head, and the illustration accompanying this article gives one a good idea of its general construction.

One of the new and exclusive features of this machine is the fitting of all drive shaft bearings with die cast split bushings of a high quality anti-friction metal. These bearings are interchangeable and insure long life and easy replacement. Drive pulleys and cones carry wide belts, while with the generous bevel and back gear ratios abundant power is delivered to the spindle. Long range of the head and spindle on column permits the use of large jigs. Back gears are of the sliding type, fully enclosed and operated by a single lever. Spindle is provided with ball thrust bearing.

Another feature is the new geared feed with four changes and a neutral position. Feed changes are obtained by moving a knob conveniently located in the centre of the hand wheel in connection with a sliding spline, four feeds being provided for each spindle speed. The initial drive of the feed shaft is from the top cone shaft through spur gears and two-to-one spirals, the latter bronze and steel respectively. This arrangement is very compact. All gears in the lower feed box run in an oil bath and are completely enclosed. The steel worm which meshes with the extra large worm gear also runs in an oil pocket. The adjustable automatic stop of new design is quick and positive in action. Hand feed and quick return of spindle is through the medium of a three-lever spider, at right of feed box.

Special attention has been given to the oiling of the machine; all bearings are equipped with oil cups, grooves and channels, insuring proper distribution to the vital points. The loose pulley is self oiling and will run several months without attention. All feed gears in the feed case are completely enclosed and running in oil. Particular care is given to the finish of this tool, spindle sleeve and all shafts being ground. All machines are thoroughly tested before shipment.



GENERAL VIEW OF GEARED HEAD DRILL PRESS.

Positive geared tapping attachment, geared or belted motor drive, round or square table with tee slots and oil pocket, oil pump outfit complete and quarterturn countershaft are furnished as special equipment.

INSERTED TOOTH SAW

An inserted tooth metal saw is being placed on the market by the Simonds Manufacturing Company, of Fitchburg, Mass. This saw, which is designated as No. 000, was especially designed to meet the requirements for a saw to cut structural iron, I beams, channels and stock with thin walls that could not be cut as successfully with saws of somewhat similar design, because the pith or spacing of the teeth was not fine enough to keep two teeth in the cut at all times in this work.

This new saw through its arrangement and closer spacing of teeth provides for smoother running and eliminates chatter which is often noted where the teeth are placed further apart in the plate. It is a fast cutting saw and is fitted with as many teeth as it is possible to securely fasten into the plate in the Simonds proven method of holding, and at the same time retain the perfect alignment of teeth and strength of plate necessary to stand up and cut true. These saws are being made from 10 inches in diameter with kerf of one-quarter inch and maximum of 40 teeth to 50 inches in diameter, 15-32 inch or 7-16 inch kerf with 210 teeth as the maximum number.

TABLE FOR FACE GRINDING

The Badger Tool Company, of Beloit, Wis., are placing on the market a face-grinding table to be used in connection with their regular line of single-spindle disk and cylinder-grinding machines. The overall dimensions of the table are 14 by 73 inches and the longitudinal travel is 32 inches. Hand-wheel feed provided for a 4-inch adjustment toward the grinding wheel; greater movement may be obtained by resetting the main saddle on the bed. All table and grinding wheel equipments are interchangeable.

BRITISH INNOVATION IN WEAVING

It is very rarely that anything really new in weaving machinery makes its appearance. Nevertheless a British firm has just introduced a new type of loom which involves many radical departures from the traditional type. From the practical standpoint its main feature is that it can be tended by a young girl, who can be taught the necessary operations in a few hours. The new loom has a wide range of products and already artificial silk, sponge cloth, and even blankets have been woven on it.

The Cost of Strikes

THE Bureau of Labor Statistics at Washington has concluded that it is no use trying to compute reliable figures on the cost of strikes. All data pertaining to the matter, where an attempt has been made to reduce it to money, is of no value.

The bureau refers to the steel strike as showing the difficulties of gaining accurate information as to costs. Because of the difficulty of ascertaining the number of persons actually on strike and the different statements made by the two sides, it is held to be impossible to get figures of any value.

The innocent third party, the public, the bureau says, seldom suffers a money loss, its losses being mostly in the matter of inconvenience.

In Britain, right now, there is a concrete case of what it means to the third party. If the miners persist in their strike it will mean in a short time that hundreds of thousands of workers, who have no quarrel with their employers, and who cannot afford to do so, will be thrown out of work by reason of the absence of coal to keep their places of employment in operation.

The Matter of Trades

ONE finds more attention given in the daily papers than even to the matter of trades and apprentices. In a recent issue of the Woodstock Sentinel-Review there was the following:—

"In the good old days there were plenty of barrels at 25 cents each. But in those good old days there were cooper shops in almost every town and village. Cooper shops are disappearing. Is anybody learning the cooper trade these days? The old-time shoemaker has practically disappeared. Where he survives at all it is as a cobbler. The old-time tailor is disappearing. Many of those who still keep up the struggle for existence earn more of their living from mending than from making. Tinsmiths and plumbers tell you it is almost impossible to get boys to learn these trades. Boys will not serve the apprenticeship necessary to learn a trade when they can go into a factory, and, in a few weeks, learn to run a machine sufficiently well to earn a man's wages."

The New Liskeard "Speaker" discussed the matter from another viewpoint, saying in part:—

"But the war has brought about a still greater change for the boy and young man, because he can get such good pay at almost any kind of work, will not 'lose the time' to learn the trade. We expect it would be next to impossible for any of the manufacturers to get apprentices to-day, unless such apprentices are paid next to journeymen's wages. These boys and young men only think of the present. So far as they are concerned, the future may look out for itself. If we are right in our view of this matter, soon there will be no master mechanics. So called 'handy men' will take their places. Who can foretell what changes will take place during the next ten years?"

There is a condition of affairs here that Canadian Machinery has, on many occasions, tried to place before its readers.

The years of discipline that were spent in learning a trade were not wasted. The small wages of those earlier days enforced thrift often to the point of actual want, but it left an appeciation of the worth of a dollar that is painfully absent in many a young man to-day.

It will be a sorry day for the future of this or any other country if we pass up the learning of a trade as waste time, forgetting the stalwarts in all lines who have come up through the ranks, and the foundations for whose greatness were laid in the stringent and memorable apprenticeship days.

THERE are an increasingly large number of people in the business world who are believing that Royal Meeker, commissioner of the United States Department of Labor, said something very true when he stated: "It will take a long time to deflate the world's inflated currencies or to inflate the world's deflated supply of goods." In another way, we are in for a period of high prices for some time yet. It is not until one gets down to facts that he realizes just where prices have hopped in the last few years, say since 1914. Unfortunately, we have not yet developed in this country the art of keeping statistics in such available form as they have them in United States, but conditions are much the same, as in many cases we get our supplies from that country. In the matter of lumber, the average of increases since 1914 shows: Yellow pine, 340 per cent.; Douglas fir, 527 per cent.; spruce, 165 per cent.; hemlock, 240 per cent.; and oak, 444 per cent. In the structural side of building the following materials show: Structural steel, 126 per cent.; steel bars (used for reinforcing), 135 per cent.; wire nails, 188 per cent.; steel rivets, 168 per cent.; and electrolytic copper, 41 per cent., now, but it has shown increases as high as 119 per cent. Cement shows 77 per cent., common brick, 350 per cent.; crushed stone, 95 per cent.; sand, 150 per cent.; and gravel, 122 per cent.

WHAT France intends to do with the money derived from the sale of goods which she purchased from the United States at the close of the war is a question which is now puzzling that country. On the termination of the war the French Government bought from the United States stock or "surplus war material" which cost the United States approximately $1,500,000,000 for $400,000,000. This stock consisted of both moveable and stationary material ranging from equipment that had never been used to some almost worn-out, and included everything needed in the prosecution of modern warfare. It was supposed that France would use this material in her own reconstruction work, but several sales from this stock at home and abroad since the armistice, the most recent being to Harris Bros., a U.S. firm, have raised the question as to whether France intends to apply the proceeds from these on her loans from the United States amounting to $2,997,477,800. Those in touch with the situation believe that France may have applied the proceeds on her indebtedness resulting from her popular loan of 1917. It looks as though the Frenchman was highly efficient in financial matters to buy at bargain prices and sell in a higher market and receive payment in premium money.

The Secret of Henry Ford's Outstanding Success

Was forced to develop his factory to supply the demand he created.

THE editor of the New York "Sun" shatters accepted theories and thereby shocks his readers by a habit he has of doing his own thinking, of leading, not following the public, and making his own analysis of conditions. When the press and public of the United States were enthusiastically and thoughtlessly happy over the enormous business coming to them for steel and other material for a war-devastated world, that paper burst the bubble by showing that there was more steel in an ordinary New York skyscraper than would rebuild the whole damaged area in Belgium and France.

If we were to ask the why of Henry Ford's supersuccess, there would be a hundred per cent. reply that it was entirely due to his ability as a manufacturer.

The "Sun" editor, applying the analytical test, finds that the great, unthinking public is again wrong. Instead he shows that Mr. Ford is primarily a great salesman or merchant, that he was forced to develop his wonderfully efficient factory to supply the demand made by himself as a merchant. The "Sun" says:

Henry Ford Points the Way

Henry Ford is both a great manufacturer and a great merchant. He could never have become the great producer he is if he had not been a great merchant. It is because Ford is the outstanding genius of the automobile world as a merchant that he has become the outstanding genius of the automobile world as a producer.

The Ford automobile is primarily what it has come to be because Ford has greater genius than any of his competitors in the distribution of his car. With the price right and his selling organization right the production of his car became a matter of ways and means of keeping up with the demand. And as the output increased the cost of production decreased, and as this decrease in cost was deducted by the great merchant from the selling price the demand automatically increased.

In his early days Henry Ford was a mechanic at the bench. It was as a mechanic that he dreamed out the now world-famous Ford car. He had never been a merchant, had never fancied that he was endowed with the qualities of a merchant, though it was as a merchant that he was and is nothing short of a genius of the first order.

And now he has given us fresh evidence of his vision as a matchless distributor of the products of his mammoth workshops in the drastic slashing of prices to pre-war levels. In this stroke Henry Ford has pointed the way for all other producers, all other merchants. The country is headed for lower prices, pre-war prices or prices thereabout.

No man, no body of men, no association of interests working in collusion or co-operation, however gigantic, can hold up these unnatural and exorbitant war prices. What Henry Ford has done in his far-reaching vision other men must do or they cannot survive.

A review of the successes and failures in Canadian manufacturing confirms the "Sun." Walter H. Cottingham, probably our outstanding present-day success, developed and acquired the largest paint and allied factories in the world to fill the demands created by him as a merchant.

Senator Nichols was induced to take over and direct the destinies of the General Electric Co. and allied interests because as a merchant he had created his own market for electrical products in Canada.

Sir George Foster, our Minister of Trade and a member of the Imperial Trade Commission, expressed this view in 1914. He said the commission had found in Australia that German trade was growing steadily because the Germans were better merchants. Their superior salesmanship was overcoming the handicap of the superior quality of British goods and the strong national sentiment that extends throughout the Empire in favor of the British manufacturers.

Canadian manufacturers are in a less fortunate position than they of the Mother Country. The latter have well organized plants, trained workmen and established connections. The majority of men at the head of Canadian industries have worked up from apprentice boys. They have had to build new organizations and train workers. It has been a mighty strenuous career. Neither the thousands of employees nor the country as a whole appreciate what we owe these pioneering executives. But their thoughts have been on production and they love their factories and their employees. They have neglected their accounting and merchandising departments. The "Sun's" editorial suggests a new thought to many, and a very timely one. We must give more attention to selling our products at home and abroad. In this way only can most of us hope to keep our workers and plants running full time.

But salesmanship means more than taking orders. The buyer must be able to pay. The products must be what he wants, and what he orders; and our service must be prompt, reliable and satisfactory in every way. That it has not been is shown by the persistent complaints of our late Overseas Commissioner Lloyd Harris and many of our local Trade Commissioners. But it can be made satisfactory.

BROWNED ALUMINUM

To protect aluminum and aluminum alloys from corrosion, L. von Grotthuss has tried the experiment of browning the metal electrolytically. The aluminum is suspended in an electrolyte consisting of a sulphur compound of molybdenum and zinc is used for the anode. The cell is maintained at a temperature of 60 deg. to 65 deg. C. The aluminum is soon covered with a dark brown coating. The metal may be bent or rolled without cracking the coating. A piece of aluminum thus coated was immersed in a salt solution for two months without showing the slightest traces of corrosion.—Abstracted from Metal and Iron.

MARKET DEVELOPMENTS

Which Way Will Steel Market Move Now?

Dealers Claim That It Has Become a Case of Seeing Which Party Can Wait the Longest—No Change Likely in the Prices of Small Tools in Canadian Market.

PITTSBURGH openly admits that the steel market there has developed more than usual flatness, and that there is a falling off in consumption. While this may be so, yet it is not reflected to any great extent in Canada. In fact some of the merchants in the steel and iron business claim that the situation has become stronger during the last week. A few days ago, they claim, there was a feeling that the bottom might fall out of the market, but it has become fairly well established since then that there is not going to be any sharp reduction in prices.

Some of the material that has been turned loose by the cancellations of the automobile plants is being taken up by other concerns, and there are cases where considerable relief has been afforded by this action.

Dealers in small tools do not look for any change in the prices of their products, claiming that right now they are selling high speed goods at from fifty to seventy-five per cent. below the schedule that was prevalent during the war. There have been reductions made in several lines of small tools during the last few months, and there seems to be a feeling that present prices will stick for some time.

It is too early to predict just what effect the British coal strike is going to have on British firms exporting steel and tools to this country, but some dealers hold that the effect will be felt in a very short time, as there is not much stock held in this country.

The scrap metal market is very dull just now. Dealers do not want to take on any more tonnage than they can dispose of almost at once in the present market, so the most of the business is being done in small lots. Prices quoted are more or less nominal, and cannot be guaranteed. Some of the trade look for a lower price, and when this comes they believe trade will increase.

CANCELLATIONS CAN BE TAKEN UP TO MAKE SPOT DELIVERIES NOW

Special to CANADIAN MACHINERY.

MONTREAL, Que., Oct. 21.—There is still a tense atmosphere surrounding business transactions and buyers continue to show a conservative attitude when looking for material. Consumers are purchasing only for urgent requirements and the placing of orders for material and equipment is only done when the goods must be obtained to carry on immediately. While the situation in England is not expected to have a direct bearing on Canadian conditions, the tension contingent on a possible strike there has been felt in this district. Should this trouble be of long duration it would first affect the coal situation here, as efforts would probably be made to bunker trans-Atlantic vessels at Canadian ports.

Under the surface of apparent firmness the steel market is undoubtedly developing a nervous tendency which will ultimately be manifest in a slowing down of demand and a consequent effort to meet the situation by lower prices. Already some dealers have been asked regarding the possibility of cancelling a portion of orders placed for material, but little definite action has been taken to advise the mills to this effect, as the bulk of orders now on the books are not subject to any cancellation. In some instances it may transpire that dealers will endeavor to dispose of some of this stock by redistribution to customers requiring spot supplies. The better service given by the railroads has facilitated the transportation of raw and finished materials, so that delayed deliveries of steel and other commodities is not so serious a factor in market conditions.

Outward indications of price reductions on machine tools are not pronounced, but the reluctance of the dealer to assume a definite attitude of optimism might imply that weakness may develop at any time. "The general demand for tools of all kinds is less in evidence and enquiry for next year's business is falling off considerably. This, we feel, is only temporary, and we are looking forward to a renewal of activity with the turn of the New Year." This statement by a dealer here gives the impression of a quiet period for the remainder of the year. The old material market continues in a lifeless mood and trading is very light, particularly in the non-ferrous lines. Machinery cast retains the centre of interest in the volume of business done.

WAITING GAME IN STEEL TRADE

Can Dealers Hold Out Longer Than the Rollers in Price Adjustment?

TORONTO.—Although the week was broken by the holiday, business is by no means that of a small week in many lines. Machine tool dealers believe that the understanding is becoming general that price reductions are not going to materialize for some time. They also hold that price reductions would not have brought any more business into the market. The importation of British machine tools may be interfered with if the strike of the coal miners is not settled. Reports are that there is not much coal in any of the plants, and the steel makers are beginning to cut down already. The blast furnaces in the Middlesborough district are already damping down, and thousands of furnace men and steel workers are idle already. The Tees-side district provides a third of the whole British output of pig iron.

The steel market is just now at the

Warner & Swasey Screw Machines

For large output and close limits—If you are figuring on screw machine work you can depend on W. & S. machines being right for the job.

64 Front Street West
TORONTO

point where it is waiting to see what is going to take place. One of the merchants sized up the situation to-day as follows:

"We are through with the independent mills for the present and it means that we are in a waiting game, and it is a question of who can stand it the longer, the mills or us. I believe that in the past week there has been a settling of the market. Just a few days ago everything seemed more or less up in the air, and there was a feeling that prices were likely to be shot to pieces all at once—that the premium mills would at once hop down to the level of the corporation prices, and there might even be a sagging of these, but there has been a change in the last few days. The trade has come to realize that the bottom has not dropped out of the market, nor is it going to. There is still a great demand for many lines of steel, and the cancellations that are coming in are nearly all from one or two lines of industry, and their tonnage can quickly be taken up for spot deliveries if it is decided to allow them to cancel." It was hinted in some quarters that the dealers here would be willing to pay up to 6.50 base for black sheets from the independents for quick delivery. The corporation price for Canada is 5.55.

There is a better supply of cold rolled shafting than for some weeks past owing to cancellations by the automobile trade, which formerly had been a large buyer of this class of material. There are many shops all over the country, and many firms which make a business of furnishing complete equipment, that will be glad to take on any cold rolled they can find.

The boiler tube shipments are reported as better than for weeks past, but it will be some time, even with the very best of shipments, before the deliveries will begin to even up with the demand.

The Small Tool Market

There is a nice lot of business moving in this market, at least some of the dealers are quite well satisfied with what they are getting. They admit that there is no large buying going on now, but for all that there is a good turnover and the stock is moving out well.

"Do we expect any changes in small tools? No, we do not," was the opinion given by one of the dealers this week. "It was only a few months ago that reductions were made in high-speed drills and cutters. This was done to enable us to meet outside competition, but the reduction has remained, and I think you will find that right now the prices of high-speed drills, cutters, etc., is about from 50 to 75 per cent. below the prices that were being charged in war times. You can look a long time in the machine-tool field before you will find anything that has done that. We believe that present prices are going to stay for some time unless something very much out of the ordinary takes place."

The scrap metal market shows little or no change this week. Prices that are quoted elsewhere in this paper may or may not be paid by the dealers, depending on the need they experience for purchasing. "In some lines we do not want to take on material at all," is the way one dealer stated the case to-day. "In others if we take anything at all we want only lots that we can handle in the present market. It looks to us very much as though the market is due to come to lower levels."

NOT SO DULL IN YEARS AS NOW

That is What Report Says of the Tool Trade in New York This Week

NEW YORK, Oct. 21, 1920.—The machine-tool industry is marking time. Buyers show very little interest, and the efforts of machine-tool manufacturers and their representatives to "stir up" orders are generally unavailing. The market has not been quite so dull in years. As has been previously reported, the machine-tool industry is centering its hopes for future business largely on railroad purchases. But it must be admitted that the Eastern roads

as yet have shown no definite indication as to when their inquiries will come out.

With the exception of a reduction of 15 per cent. in one line of internal grinders, there has been no move on the part of machine-tool manufacturers generally to make price reductions. While reductions have been considered by some companies, their ultimate decision has been that lower prices would not at this time stimulate any substantial amount of buying.

The price guarantee is becoming more general, and this seems to meet the view of those buyers who have actual need for tools immediately. Some guarantees run for as long as six months, which means that the buyer will be given a rebate equal to any reduction which might be made within that period. In most cases this is a one-sided agreement; that is the buyers decline to agree to pay an increase in price should there be any. Legally, of course, a contract is not a contract unless it works both ways, but sellers in some instances seem willing to make the one-sided arrangement if by so doing they can land an order.

STEEL MARKET HAS VERY FEW URGENT BUYERS AND IS WEAKER

Special to CANADIAN MACHINERY.

PITTSBURGH, October 21.—The iron and steel markets continue stagnant, as is naturally to be expected. When dull times have prevailed for some time there is necessarily some business being done, but in the early part of a generally dull period there is particularly little business because buyers are getting deliveries on previous purchases. Conditions to-day show that buyers have done what they usually do in an active period when material appears scarce, they have overbought. It looks as though consumption had greatly decreased, because the same buyers who a couple of months and more ago were importuning producers for heavier shipments are now acting as if they were receiving too much material. Consumption, however, has decreased very little. The main change is a change in the mental attitude of buyers. Such changes frequently occurr almost overnight.

Pig Iron Slumping

Whatever may have been true of the advances in pig iron prior to the sharp advancing movement of last August, there was no difficulty in seeing last August that the advances made in that month were ill-timed. The volume of buying was very small, much less than is usually required to send prices upwards, and it looked very much as if the advances were based upon little more than a whim of the furnacemen to get pig iron up to the interesting objective of $50. The course of affairs now in the pig iron market reflects the artificial character of the latest of the advances, for pig Iron instead of declining is slumping. A difficulty is that inquiry is so light that sometimes the prices at which producers would really be willing to sell are not disclosed. Thus Bessemer iron is still quotable nominally at $48.50, valley, the price to which it advanced in August, although it is certain that furnaces would sell at less. It requires a precise quotation, or an actual sale, to develop the price at which furnaces really would sell.

In the case of basic iron there are clear cut developments. Basic had also advanced in August to $48.50, valley, and during September the market remained, nominally at least, at that figure. Since the beginning of this month it has been clear that some furnaces would be glad to sell at less. A couple of weeks ago a middle interest was understood to have bought 3,000 tons at $45, valley, then selling 1,000 tons to a consumer at $46. Since then there has been further weakening. It is thoroughly established that several sellers have quoted $42, valley, without effecting sales. In the case of one consumer at least, the reason they did not sell was that the consumer got the iron he needed, 1,500 tons, from a middleman at $40, valley, and the middleman had offered 3,500 tons, so that it looks as though there is 2,000 tons ready for some one to buy at $40. According to common practice in quoting the pig iron market, transactions in which a middle interest figures are not regarded as setting market prices, hence the quotable market to-day on basic iron is $42, valley, a price at which iron has been offered, with no takers, representing a decline of $6.50. It was early last February, on the advancing market, that basic got up to $42, and thus the market has declined as much in about three weeks as it had advanced in six or seven months. Usually the market declines at about the same rate as that at which it had previously advanced, and the more rapid decline this time confirms views entertained previously by many in the trade that the advance was partly artificial, and not well based.

As to foundry iron, it is in the same class, marketwise, as Bessemer, not enough business having been done to show where values really stand. The trade calls the foundry iron market nominal at $47, valley, or $3 under the price attained in the August advance. Doubtless on an attractive inquiry furnaces would quote considerably less than $47.

Attitude of Steel Producers

In past times when the steel market became quiet the mills would hold together in the matter of prices, keeping up their quotations until they had delivered most of their contract tonnage. There was no advantage in reducing prices to effect a few fresh sales if thereby cancellation of existing contracts would be invited. At those times, however, the independents and the Steel Corporation were together. Now the independents have to play their game alone, and it is a question whether they will hold together. Some steel makers profess confidence that they will do so, and that production will be allowed to decline and decline again before mills reduce their quotations to the Steel Corporation level, which common opinion has it is the ultimate objective. Not a few observers expect prices to continue to weaken as they have been doing in the past few weeks, and if they continue the pace set thus far it will be only a few weeks, or two or three months at most, until the independents with few exceptions are down to the Steel Corporation level. Some observers even profess doubt whether, even if the independents adhered to their present quotations, the demands on their contracts would be sufficient to enable them to keep above a 60 per cent. rate of operation in the winter.

Steel Prices

There has been particular weakening in strip steel. While the automobile industry does not consume any large part of the steel output as a whole, say 4 or 5 per cent., averaging the year as a whole,

POINTS IN WEEK'S MARKETING NOTES

Pittsburgh reports that the iron and steel markets continue stagnant, and the belief is expressed that consumption has greatly decreased.

Some observers claim that if the independents maintain their prices they will not have enough booking to operate at 60 per cent. capacity in the winter.

The top of the plate market in Pittsburgh is now 3.25, while as low as 3c has been done in consideration of an attractive tonnage.

Some of the independents have sold black sheets as low as 6.50.

Cold rolled shafting is more plentiful owing to cancellations that have been made by automobile concerns.

Dealers in small tools point out that they expect no reductions as they are selling high-speed now from 50 to 75 per cent. under war figures.

The scrap metal market is weakening toward lower prices. Dealers do not want to accept large deliveries at present prices, and only small lots are moving.

they do use a great deal of strip steel and thus their light operation at this time is reflected in the strip market. Last August, when independent prices were well established at 5.50c for hot rolled and 8.50c for cold rolled, there were predictions that the market would go up half a cent, but instead of doing so it has been declining, and it is probable that one could buy now at about 5c for hot rolled and 8c for cold rolled. Cold finished steel bars are easier, there being little difficulty in buying at 4.25c, while a few weeks ago sales at 4.25c were rare. In plates 3.25c is now the top of the market instead of the bottom, single carloads being available at that figure, while attractive inquiries bring out quotations down to 3.10c, and 3c has been done in at least one case. In structural shapes there is conflicting testimony. The independent price had been 3.10c, against the Steel Corporation's 2.45c. Some interests claim 3.10c is being adhered to, while others report transactions at 3c and under, down possibly to 2.70c.

The sheet market is easier. Independent quotations generally are 6.75c to 7.25c on common black, but it is said that one mill has sold at 6.50c. It is known positively that a mill "married" contracts by selling to a customer at 6.50c when the customer wanted to cancel a contract placed some time ago at 7.50c. Galvanized run from 8.25c to 9.75c and blue annealed from 5c to 5.25c.

The Week's Events in Montreal Industry

Fraser S. Keith, general secretary of the Engineering Institute of Canada, officiated last week at the organization of a new branch of the Institute at Moncton, N.B. Officers of the branch are W. A. Duff, chairman; J. D. McBeath, vice-chairman, and M. J. Murphy, secretary treasurer.

Further airing of the Ross rifle controversy is promised, following a recent address by Canon Scott of Quebec, senior chaplain of the First Canadian Division during the war, before a large gathering at Calgary last week. He is asking for an investigation and a definite finding so as to enlighten the people of the country regarding the facts of the entire case.

A portion of the plant of the Davie Shipbuilding Company at Levis has been acquired by the lumber firm of Knox Bros. of Montreal. The buildings will be equipped with machinery for resawing and dressing lumber, and it is expected that the finished output will approximate twenty carloads of lumber per day. Yard storage capacity will be about 15,000,000 feet of lumber, and the drying shed will accommodate one million feet. It is stated that operations will be commenced at once.

At the October meeting of the Canadian Railways Club the subject for discussion was a paper on "Patents of Invention," by William McFeat, Patent Attorney of Montreal. In his address Mr. McFeat gave a brief but clear description of the early history of patent laws, the importance of invention to community and country, the fundamental principles of obtaining and maintaining Canadian patents, and likewise how to realize on patents granted. Thirty new members were added to the roll at this meeting.

Following the recent ruling of the board of railway commissioners, the Province of Quebec has taken steps to regulate the supply and distribution of fuel by appointing J. W. Lewis as fuel administrator. Mr. Lewis held this position when the situation necessitated control last year. While coal distribution will be left almost entirely in the hands of the trade, the office has been recreated to keep a rigid check on tonnage movement and to be prepared to deal with complaints should the occasion arise.

In order to provide themselves with adequate supplies of silicate bricks for the maintenance of their blast furnaces, the Dominion Iron and Steel Company are taking steps to develop a large tract of land rich in silica, which the company acquired at Neils Mountain, near North Bay. The road bed for the necessary hauling of the material from the property to the adjoining railroad is being prepared by slag brought from Sydney, N.S. The silicate brick plant is now being constructed at Sydney and manufacturing is expected to commence in the near future, as soon as sufficient material has been shipped from the clay beds up north.

The business firm of Forrest, Jackson and Forrest has recently been organized and will henceforth carry on business under the name of the Sheffield Engineering Supplies, Ltd. In addition to the Dormer high-speed twist drills now carried in stock, the firm will carry a complete line of Dormer high-speed steel milling cutters and reamers. These lines are all made by the Sheffield Twist Drill & Steel Company. Other lines carried by the firm will be high grade hack saw blades and files. Capt. H. H. Pinch has been added to the organization and will have the position of vice-president. E. Jackson will retain the position of president, and E. B. Forrest will be secretary-treasurer.

Emile Belanger, 26 years of age, an employee of the Consolidated Rubber Company of Montreal, was, last week, awarded $17,500 for the loss of two arms, which were amputated following an accident in April last year. It was proven that the machine was inadequately protected with safety appliances, that these appliances had been recommended by workmen, and that delay in installing the necessary protection was the cause of the accident. "In these circumstances," Justice Surveyor said, "there is reason to declare that there was inexcusable fault on the part of the company defendant, and therefore it ought to be condemned in damages as though the accident in question were governed by the common law." Plaintiff sued for $25,000 damages under the Workmen's Compensation Act.

On the afternoon of October 14 an interesting event took place at the C.P.R. Angus shops at Montreal, it being the annual presentation of prizes to apprentices for the work accomplished during the past year. The prize winners in order of merit were: W. Morrison, machine apprentice; A. E. Watson, machine apprentice; C. Girdwood, tinsmith apprentice; T. Brown, machine apprentice; R. Thomas, machine apprentice; L. Kinlough, carpenter apprentice, and E. Hardy, carpenter apprentice. The prizes were in the form of several volumes of reference books particularly selected for the various branaches of the work in which the different boys are engaged. In addition to awards for local work, prizes won at the Canadian National Exhibition, by apprentices A. Sanfacon and L. Lebouc, for architectural drawing, and a special prize to T. Brown for mechanical drawing, were also presented. The presentation was made by Mr. John Burns, works manager, and several works officials gave short addresses on their past experiences and the progress that has been made during the past fifteen or twenty years.

FIRMS WANT TO ESTABLISH TRADE RELATIONS WITH CANADA

Information regarding the following lines can be obtained by communicating with this paper and mentioning key numbers.

Sheffield Makes, Thinks and Talks Steel

Mr. Swallow, of Ingersoll, Has Had a Chance to See the Development of Changing Industrial Life in That Centre—Men There Are Experts in All Matters Pertaining to Steel

MR. H. SWALLOW, manager of the Ingersoll File Co., returned a week or so ago from a brief trip to Sheffield. In reply to a query from Canadian Machinery regarding conditions in the steel world of Sheffield—for it's all steel there—Mr. Swallow writes as follows:

To understand the conditions in Sheffield to-day it is necessary to step back a generation or so.

Originally it was a city of small units, each unit self-contained and making articles from raw material to finished product. Several of these units would occupy one building whence grew the factory which might contain up to a hundred such units each doing all the operations on a similar article. Eventually for financial and other considerations they grouped together under one executive and one firm name, but maintained their working identity. An order for five dozen tools would be received and would be handed to one of the groups where it would be completed. When orders grew in magnitude overlapping was inevitable. The system evolved craftsmen of wonderful ability but it also evolved weird and wasteful methods of handling and routing materials.

The war taught what could be done in mass production. The urgency of patriotism was behind that. Then came the armistice, and found a world utterly unstocked of all the products Sheffield loves to make—and can. But operating costs kept rising, the demands of labor increased, until the English steel man found himself in the position of his Yankee competitor years ago who was faced with the greater individual production, and the lower labor costs of Sheffield.

The demand, therefore, was for speed of production, smoothness of operation, and modern factory methods. Sheffield gasped at the prospect, grunted its disapproval of the departure from grandad's ways of doing business, but went to work to solve these problems. The modern buildings erected for shell production were utilized, expert factory organizers were called in, deals were made with the unions, and everybody rode on a wave of prosperity such as they never dreamed of. Labor kicked, and is still kicking and therein is the fly in the ointment. Production has slackened in the past few months because of the unions' resentment of labor-saving innovations.

If Sheffield can solve that problem she will again be the steel centre of the world. She has the right materials, the best methods, and the finest steel craftsmen on earth, steel men with generations of steel workers behind them who think, talk and live little else but steel and steel products. Any Canadian toolmaker who could command the same class of help would cut a swath a mile wide through the American continent.

The failure of the much-heralded coal strike in England was due to two causes: The union was not financially ready for it, and the public was, as a whole, hostile. No strike can hope to succeed in the face of popular disapproval, however "red" its leaders may be. An armistice has been called, but it may be broken at any moment. The next big strike in England will be a show down. It may culminate in a lockout by the employers who have already adopted that plan with the electricians. After a settlement (not another compromise) look out for Sheffield.

The executives who run the industries there are young men, educated by practical steel workers, and schooled in the amazing production of war years, live wires like Harry Brearley, the inventor of stainless steel, who are always a lap ahead in the production of special steels. The writer met one man much under 40, who is managing director of five large enterprises, and manages them profitably and well.

Recently, gigantic mergers of some of the oldest and wealthiest firms in Sheffield have taken place. This will further consolidate the varied interests, and has undoubtedly been caused by the understanding arrived at by the French and American steel makers who have eyes on the fat market of the European continent.

It is to be seen that Sheffield is gradually in her thorough English manner assimilating all that she can profitably use of new ideas and methods. She has always traded in the far corners of the earth, and when she gets her house in order, other nations will have to set their pace by hers.

Already her cutlery and small tools are appearing in quantity in this and other countries. Hér steel makers are catching up and making fairly quick delivery. She is backed by immense wealth and can wait.

CLAIMS OF CANADIAN SHOPS FOR U.S. SHELL WORK ARE SETTLED

THE work of settling claims that Canadian munitions plants had against the U.S. Ordnance Department has been completed, and the last of these has been paid. The matter of disposal of the property of the Motor Trucks at Brantford is still in court, but a decision is expected very shortly.

One of the officials of the U.S. Ordnance Department, speaking to Canadian Machinery of the disposal of the property and the work connected with the making of the settlements, stated: "I do not think any of the men who have been on the settlement board would care to go through the experience again. In the rush of getting results when they were very badly needed there was not the time nor the machinery necessary to get a complete record of everything, and some of the munition makers themselves had to carry a good many of their accounts and memos in their pocket. When it came to making a settlement of course we looked for documents, for vouchers, for written orders, etc., and in a good many cases they were not in existence.

"When we came to dispose of the tools that were the property of the Ordnance Department, we met the machine tool builders of United States, and agreed then to do everything in our power to keep from upsetting the market for new tools, which would have resulted had we gone ahead and dumped our stock on the market. Single purpose machines were scrapped, and we had to see that they were sold as scrap. We found there were parties in both countries who planned to secure the machines at scrap prices and rebuild them into some sort of mongrel lathes and put them out at a fair price as a cheap machine. Our stand was that they had no business to do this, and that if they bought a machine as scrap and at scrap prices, it was up to us to see that they got scrap and nothing else. We did not believe that they had any more right to profiteer in this matter than we would have, and so, when a machine, generally a single purpose affair, was set aside to go at scrap prices, we generally undertook to see that it was well struck with a drop hammer before it had a chance to leave our hands."

The U.S. Ordnance Department is undertaking the publication of a magazine at Washington, the material for which comes from men who are or were engaged in the Ordnance work during the war. The object is to preserve and place on record as far as possible material in connection with ordnance activities, and also to review the work that was carried on in the shell shops of Canada where United States contracts were placed. A number of articles that appeared in Canadian Machinery dealing with various operations in the shell shops will be drawn on the furnished information for the Washington magazine.

CONFIDENCE

THE GREATNESS OF BRITAIN IS FOUNDED ON HER INTEGRITY.

HER STRENGTH SHE DERIVES FROM WORLD COMMERCE—HER ENDURANCE FROM CONFIDENCE.

THE WAR TEMPORARILY RETARDED HER CONSTRUCTIVE EFFORTS, BUT THE POWER OF THE CONFIDENCE OF THE PEOPLES OF THE WORLD WILL RESTORE TO HER IN MORE BRILLIANT FORM THE LEADERSHIP SHE HAS JUSTLY EARNED AND PROUDLY HELD.

CONFIDENCE IS THE FOUNDATION OF OUR POSITION IN THE WORLD OF IRON AND STEEL—OUR PROGRESS DEPENDS ON IT.

WE HAVE BEEN SUCCESSFUL IN THE PAST—THE FUTURE IS BEFORE US. TO ADVANCE, WE MUST CONTINUE TO MERIT THE CONFIDENCE OF THE BUYERS OF STEEL AND IRON PRODUCTS OF EVERY DESCRIPTION IN CANADA, AND WE ARE DETERMINED TO ADVANCE.

Quick Drop in Steel Prices Not Desirable

Mr. F. H. Whitton, of the Steel Co. of Canada, Traces Conditions That Have Been Met in the Market Since the Signing of the Armistice—Costs Are Still High

SPEAKING before the Canadian Wholesale Hardware Association on the iron and steel industry, Mr. F. H. Whitton, of the Steel Company of Canada, made it clear that his company was not looking for a sharp decline in prices of steel or iron. He believed that such a course would be dangerous, and not in the best interests of our industrial life.

"In January of 1919," said Mr. Whitton, "we believed that the period of readjustment had arrived. We made reductions of $4 to $6 a ton, business was depressed, some wanted to cancel orders, and there was a great curtailment of business up to June, 1919. But that was a false sign because the demands of peace time requirements immediately caused a rebound in business and you all know the pressure which has taken place from that time to the present. Up until that time labor was very scarce; it was an era of wage upon wage increase, decreased production, general dislocation of business and restlessness among the men. The public were extravagant and there was a great indulgence in luxuries. Speculation has increased during the past eighteen months. But at last a halt has been called. Our war debts have to be paid, our Government has called upon us to be economical and is taking our money to pay interest and principal. On behalf of itself the Government has had to curtail expenditures. Banks have wisely curtailed credit. The object of our banks is to maintain the interests of the country and their action indicates that the time has arrived when the first steps should be taken to adjust business towards normal conditions. There is nothing to be feared if we show a few jolts but the lessening of industrial activity will not be sufficiently severe to be alarming and those who fear a depression will likely be wrong.

"There is much work in arrears, much construction work to be done. A large demand is assured to supply our own people and the whole world. A downward trend in prices is taking place and the market will find its normal level, but what is its normal level? No one knows. When the public take all the goods produced at high prices it is useless to argue for lower prices. Speaking of hardware, we must not allow our products to be classified in our minds or in the minds of our customers, in the same list as the more speculative commodities such as coal, sugar, cotton, silks, etc.

"Regarding general conditions there is no question about them whatever. In regard to the crops this year, we have a most bountiful harvest and the very immensity of it will probably bring to normal levels the price of food stuffs.

"Those lines which require employing the least labor will come down first and to the greatest extent. Iron and steel premium prices will probably disappear, but prices will not come down as rapidly as other lines and the new normal level of steel will probably be a surprise to most of us.

"Iron and steel in its many finished forms passes through so many processes and probably employs a larger percentage than any other general commodity. Going back to the fundamental articles, we take ore. Ore in the ground is worth 10 to 20 cents a ton; coal in the ground is worth 20 to 30 cents a ton. These materials amount, with other alloys, to 15 per cent, while 85 per cent. of the value represents labor costs. You know the position of labor to-day. We may consider wages high but there is no rush downwards. There will be a recession in labor but only as conditions warrant. So we see that articles with the least labor will be affected the least.

Comparison of Prices

"I have compared prices of materials of a year ago with the present. These figures include 10 per cent. United States exchange in Canadian currency and exchange is figured on just that portion bought from the United States. The prices are for the third quarter compared with 1919 and are as follows:

Ore is 31 per cent. higher.
Coal 109 per cent. higher.
Coke 118 per cent. higher.
Fluxing stone 20 per cent. higher.
Alloys 49 per cent. higher.
Scrap 45 per cent. to 80 per cent. according to grade.
Fire brick 52 per cent. higher.
Ingot molds 57 per cent. higher.
Repair parts (iron) 42 per cent. higher.
Repair parts (steel) 20 per cent. higher.
Oils 32 per cent. higher.
Engine oil 90 per cent. higher.
Black oils 145 per cent. higher.

"Wages are the most important item," said Mr. Whitton, stating that all those present knew the increase in this line. He, however, advised that no undue pressure be brought to bear to bring down wages too suddenly.

Mr. Whitton pointed out that the above figures have greater significance when it is borne in mind that there are four or five tons of material in one ton of steel.

"There is a great shortage of iron and steel," said Mr. Whitton, "it being essential in so many different requirements such as machinery and production of other goods, in farming, mining, etc. The demand in Europe is also large and their production has been decreased."

Discrepancy in Steel Prices Causes Misapprehension

"Speaking of prices, there is a very great variation in the price of iron and steel between the largest corporation in the United States and the other makers and no one attempts to explain. I have no doubt that there are good and sufficient reasons for that position. Everyone concerned thinks that in Judge Gary there is one of the cleverest men in the iron and steel business. Of course we know they have advantages over any other iron and steel producer, when you take into account their costs, properties, ownership of railroads and boats, their large production. But there is some motive other than this because their exports are at much higher prices than their domestic prices. There is that discrepancy and this is apt to cause misapprehension as to values in the minds of buyers.

"In the New York Times of October 5th Judge Gary, speaking as to the effect of the advance in freight rates on prices, said: 'I hope it will not cause the Corporation to advance prices; however, I am not certain as yet what the effect will be and prices may be affected to some extent. Rails should be slightly advanced.'

"This is interpreted to mean that the Corporation is at least more likely to advance their prices than to recede," said Mr. Whitton. Continuing: "Take the case of the independents. Their costs of manufacture are very high and the difference in prices between the corporation and the independents does not mean that this is a margin of profit which the independents enjoy over the corporation. We must not expect too rapid or severe cuts in steel prices. There are only a few people who can wave the magic wand and reduce prices, but too rapid reductions would cause unemployment and the lessening of purchasing power. Only steady production will bring values down.

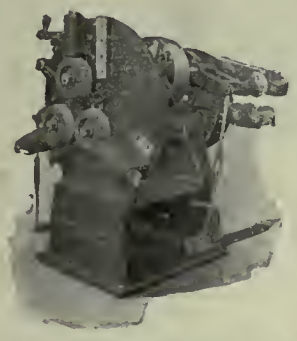
"Labor conditions are improving in efficiency. Men respect their jobs more than they did, they are willing to give you a little more labor in return for the prices that you are paying them. We have probably not reached the pinnacle by long odds, of the efficiency of labor. Wages are at the top notch and the men and the unions will fight reductions. On the other hand is the tendency to-day for the open shop. That is the only basis on which we should work.

Immigration

"Immigration is large and increasing. A great number of foreigners went back home after the armistice and when they

RYERSON

Flue Shop Equipment



Ryerson Universal Flue Cleaning Machine

The Ryerson Universal Flue Cleaning Machine is designed to meet the demand for a single flue-cleaning machine for standard size as well as super-heater tubes. It is used in shops where the amount of work does not warrant the purchase of the larger type of flue cleaning machines.

Ryerson Flue Shop Equipment is in constant use by the majority of the leading railroads.

We manufacture a complete line of machinery for cleaning and repairing locomotive boiler flues.

Spring Shop Equipment

The Ryerson Universal Elliptic Spring Forming Machine, designed primarily for railroad use, is one of the most important developments in the modern spring making industry. This machine will form elliptic spring leaves of any size and curvature used in ordinary practice, requiring but one spring maker for its operation.

It provides a rapid and scientific way to form springs, giving them the proper radius and desired camber in one operation.

Ryerson Universal Elliptic Spring Forming Machine

Ryerson Spring Shop Equipment is used in many of the largest and most efficient Railroad Spring Shops of the world. We manufacture a complete line of machinery for manufacturing and repairing locomotive and coach springs.

get money again they will be back. There are many who do not want to come back and there are a number who will not be allowed to come back. But this immigration which is coming in at the present time is going to bring us a supply of labor and more efficient labor than we have had for some time. We have been very short of common labor. British subjects do not like common laboring any more. At the same time you must recognize that the unions will make strenuous efforts to restrict immigration as much as possible through politics and other ways.

Must Keep More Trade at Home

"Another thing we can do in helping on the downward trend. Canadians have got to buy more Canadian goods and curtail purchases in other countries. Figures for August show that the United States bought from us $47,000,000 worth of goods, an increase of $3,000,000 over the previous year. In the same month we bought from the United States goods to the value of $85,000,000 which was $22,000,000 increase. We had an adverse trade balance in that month of $38,000,000.

"We must look after ourselves first as they do and which we must respect them for. This will apply to all of us in the coming year. One point you are apt to forget is that when we pay over that $38,000,000 we have to send along another $3,800,000 to pay the exchange for one month on the increase alone without the exchange which had to be paid on the total value of goods purchased. In 1920 so far we have bought from the United States goods to the value of $445,000,000 as against $335,000,000 last year, or an increase of $110,000,000 up to the end of August.

"Steel is scarce in the markets of the world. Railroads use one-third of the production of the mills and during the past five years purchases by the railways have been much more than normal. The deficit has to be made good. Construction needs of the present and future are very large. This is not a time for buyers to lose confidence. We knew how to go up, we knew how to meet our difficulties. We know how to come down and we have the ability to do it safely. All we have to do is keep our heads level, to instil in our men the idea that we have all still got to work, that all this theory that living is possible without work is wrong, and if we so order ourselves there is nothing in the way of disaster in any shape or form ahead of us."

H. W. Hutchinson, of Winnipeg, who has been elected a director of the Cockshutt Plow Co., Brantford, Ont., is well known in Western business circles but has also been associated with a number of Eastern Canadian industrial and financial enterprises. He is vice-president of the Sawyer-Massey Ltd., Hamilton, a director of the Dominion Bank, and president of the Consolidated Mortgage Co., Winnipeg Trust & Mortgage Co., Mortgage Investors Co., and other companies.

UNSETTLED IN OLD COUNTRY DISTRICTS

Too Many Strikes and Rumors of Trouble to Permit of Rapid Recovery

The Toronto office of the Department of Overseas Trade, speaking of machinery and engineering in the home country, reports:

The demand on home account has, for most descriptions, continued quiet, and manufacturers are turning their attention increasingly to export matters. Some sections are, it is true, well employed, notably in the case of manufacturers of textile machinery, who are stated to have sufficient orders on hand to keep them busy for some years to come; but, as a whole, these trades are suffering from something approaching a slump in the volume of orders coming forward.

The labor situation does not tend to improve matters, for, with the trouble in the electrical engineering trades still unsettled, and a lock-out having been declared, with its consequent adverse effect upon practically all branches of the engineering trades, manufacturers are acting with considerable caution.

On the other hand, the threatened strike has been averted, the claim for an additional 6d. per hour having been conceded; but the general labor outlook, especially in view of the latest developments in the coal situation, cannot be said to be favorable to improved conditions in these industries.

Signs of Progress

Oakville, Ont., is to have a new fire hall, to be built at a cost of $15,000.

Architect Carrothers, of the Board of Education, London, Ont., is preparing plans for a new Central High School.

Announcement has been made that $10,000 is to be spent in repairing and renovating the Prince George Hotel, Toronto.

Building operations are under way on the new factory to be built by the Canada Ingot Iron Co., Guelph, Ont. The cost is estimated at $16,000.

A new high school is being planned by the High School Board at Burlington, Ont. It is expected to be ready by the new year at a cost of $60,000.

The C.P.R. is having a survey made for a branch line from Harriston to Listowel, which will likely run through Palmerston with a passenger depot at Palmerston.

The Imperial Oil Co. are planning to have all the buildings on their property at Brandon, Man., removed this fall in order that an early start may be made in the spring on their $300,000 plant.

It has been announced by Maj. C. McLaurin, superintendent of the Government hydroplane station at Jericho, that an aerial substation will shortly be built at Kamloops, B.C.

A new Chinese Y.M.C.A. is to be erected in Toronto at a cost of $100,000. under the leadership of Edward Gung, a Chinese medical student at the University. The intention is to tear down the present quarters on Chestnut and build on that site in the spring.

Manitoba Medical College is to have a two-storey brick addition at a cost of $172,000. The contract has been awarded to the Sutherland Construction Co.

Engineering

A new Collegiate Institute costing $300,000 is planned by the Board of Education at St. Catharines.

Thos. Kennear & Co., 49 Front Street, E., Toronto, are planning the erection of a warehouse at Galt, Ont.

A report is in circulation that the Canada Steamship Line intend building a new terminal at Hamilton.

The construction of a telephone system from Hamilton to London to operate trains is planned by the G.T.R.

The city of Kingston is planning to build a modern 110 room hotel at a cost of $450,000 if the money can be raised by subscription.

Horwood & White, architects, Toronto Street, Toronto, Ont., are preparing final plans for dept. store estimated to cost $1,000,000 for Hudson Bay Co.

The erection of a library estimated to cost $25,000 at Lethbridge, Alta., is contemplated by Carnegie Library Corp., James Bertram, Secretary, New York.

The property at 157 Sherbourne St., Toronto, has been purchased by Burgers, Ltd., and will be converted into a candy factory.

The contract for the construction of new stables costing $45,000 for the Royal Canadian Mounted Police at Point Grey, B.C., has been awarded to R. Moncrieff.

The Mackinnon Steel Co., Ltd., Sherbrooke, Quebec, has received an order for steel for the coal trestle and steam pipe bridge from the Brompton Pulp & Paper Co., Ltd., East Angus, Quebec.

Lieut.-Col. A. G. Peuchen is erecting a four story building costing $150,000 at 191 King W., Toronto, which will be leased to the Ford Co., at a rental of $17,000 for their head office and salesroom.

A wire mill is to be added to the present plant of the Steel Company of Canada, Hamilton, at a cost of $250,000. It will be the largest of its kind in Canada, and will provide employment for 300 men when completed.

When the engineer, Mr. Achison, revises the plans for the new Deaf and Dumb Institute at Portage La Prairie, new tenders will be called as the tenders offered previously were for a minimum of $1,300,000, while the committee have but $1,000,000 to spend.

The Dominion Envelope and Carton Co., Toronto, have completed a transaction by which they take possession of seven acres of the commission's property at the Eastern Gap, Toronto. Work will commence in the spring upon a building 300x500 feet and one story high.

TRADE GOSSIP

More Coal Coming.—It was stated by an authority this week that coal would probably be more plentiful next month with the closing of navigation on the upper lakes. At present the mines are sending the largest portion of their output to Western Canada while they can take advantage of cheaper freight rates by water. With the closing of navigation in the near future, Toronto and central Ontario district will come in for its share of attention.

Germany Gets Order.—Canada has lost the order for 2,400 steel railway cars which the Belgian Government, through the Canadian Trade Commission, sought to place with manufacturers in this country. Instead of "made in Canada" cars, the Belgians will ride in coaches of the "made in Germany" variety when the order is filled. Advices to the Trade Commission are to the effect that the Belgians have placed the order with Germans and will pay for the railway material with foodstuffs which are to be supplied to Germany.

Plate Mill Record.—The new plate record of the Dominion Iron and Steel Company, at Sydney, broke all previous records for production when 260 tons of plates were rolled in one day. The regular daily production of the mill is about 200 tons a day. About two months ago the 240-ton mark was reached. Last week the mill ran without a hitch of any kind, resulting in the establishment of the new 260-ton record. The greater part of the plates which are being run at the present time are being shipped to Halifax, Montreal and other Canadian cities. As yet no further foreign orders have been received.

Locating in Toronto.—West Toronto's building operations include another large factory, which will employ a large staff. Grinnell and Company, of Canada, situated near Bloor street on Dundas street, having decided to manufacture in Canada are putting up large machine shops and foundry adjoining their present office building. The work is now well in hand, and the buildings, which will stand upon about two and a half acres of land, are to be of reinforced concrete, and will extend from Dundas street right back to the railway tracks. The machine shops will be 180 by 52 feet, and the foundation 210 by 100.

Rather Buy Than Build.—Although no statement is being made in advance of the declaration of the successful bids, the Canadian Pacific Ocean Services have put in tenders for some of the German passenger vessels which are being disposed of by the British Government. It is probable that at least one first-class and one second-class boat may be secured. The company prefers to buy rather than to build, because of the high cost of construction to-day, which Sir Thomas Fisher recently commented upon very strongly. The Empress of Canada recently launched on the Clyde, cost, roughly, £1,700,000, as compared with £550,000 for which it could have been constructed before the war.

Who Did This?—Trailers purchased by the Ontario Power Commission for service on Windsor Street Railway System cannot be used until extensive alterations have been made. According to an employe of the Commission, it has been found impossible to keep the cars on the rails, because the wheels are one inch narrower than those in use. It will cost several thousand dollars to make the necessary changes.

Ask Injunction.—Following the sale of the Cramp Steel Company's plant in Collingwood to the Baldwin's Canadian Steel Corporation Limited, the municipality made a seizure of the plant when it was found that it was the intention of the purchasers to move the equipment to Toronto. The reason for the seizure was the alleged arrears of taxes, which, with the compound interest to date, reaches almost $200,000. The original owners claim that there was an agreement with the municipality whereby the arrears in taxes would not be collected, but this was cancelled following the sale. The Baldwin Corporation claims that before the sale was completed they secured a statement from the town treasurer that there were no arrears of taxes, and also obtained a receipt for the 1919 taxes. Following the seizure an injunction was asked by the company restraining the town officials from seizing the plant, but no answer has been filed in defence.

A B C OF WELDING

(Continued from page 61)

valves which prevent change in the preheating flames when cutting oxygen valve is thrown open. The uses for a good cutting torch in the modern repair and welding shop are so varied that they need not be mentioned. With a little practice it is possible to cut out shapes almost as smoothly as can be done with any machine tool, bevel steel parts for welding or cut out a rivet in hurry up time.

The accompanying illustration shows the author amusing himself cutting off the end of a heavy steel ingot preparatory to its being forged into a crank shaft for one of the steamers which helped us win the recent war.

In the plants of the large steel companies many small shapes are cut with the torch from plate purchased as scrap in old boilers; steel shafting is cut to convenient lengths and salvaged. Many things are done to prevent the final loss of the dollars which the small town dealers in such articles let slip through their fingers.

61 7
384

TURRET LATHE PRACTICE

(Continued from page 373)

mounted in the same turret. The hole A is next finish bored by the cutter held in the piloted boring bar mounted in the multiple turning head at position 3 of the turret.

The chamfer D is produced by tool I, this tool being mounted in the same fixture. The surface B is finish faced by tool J, which is held in the square turret, and surface C is finish faced by tool K, which is also held in the same turret. The hole A is now reamed by the expansion reamer in floating holder in position 5 of the turret. After this the work is removed from the chuck.

Second Operation

The second operation is completed in 4.4 minutes, and the tooling is shown at 11, and the various steps are as follows: The work is placed on an automatic drawback adapter that expands to suit hole A, which was finished in previous step. The surface E is rough faced by tool L, which is mounted on the rear tool holder. The surface F is rough taper turned by tool M, which is mounted in the square turret, this tool being used in conjunction with the taper attachment.

The surface F is now finish taper turned by a special tool O, which is mounted in the multiple turning head at position 1 of the turret. The turning head is provided with a pilot that enters a hole in the spindle, thus ensuring that surface F is machined concentric with hole A. The work is next removed from the machine.

These various layouts are of particular value, insomuch that in themselves they teach a valuable lesson in careful layout. To machinists and tool designers in general, we can recommend a study of these layouts, as it will be time well spent. In a later article we will describe other tooling equipments as used on turret lathes for machining automobile differential gear cases, cast steel chuck bodies, bar stock parts and other interesting portions.

A B C OF WELDING

(Continued from page 379)

a soft brass wire. Tips for torches of the more modern stabilizing types may be cleaned by means of a steel broach inserted from the rear end.

Nothing equals pure drawn red copper for the construction of welding tips, and makeshifts for this metal should not be tolerated. There is a tendency on the part of some manufacturers to substitute "special alloy," "nickel copper," or other metals which cost less to drill and manufacture.

A popping sound emitted from the tip of a cutting torch when the preheating gases are lighted indicates a leak caused by defective seating.

Cutting Torches

Torches for rapid and efficient cutting must be built with specially constructed

CANADIAN AGENTS WANTED

FOR HIGH-GRADE AMERICAN-MADE LATHE —14 to 26. In replying state territory you can cover and cover thoroughly. Box 682, Canadian Machinery. (c22m)

AMERICAN FIRM MANUFACTURING PATented process case hardening specialty wants the services of party capable of building up sales in Canada. Box 706F, Canadian Machinery.

CANADIAN REPRESENTATIVE WANTED by U.S. manufacturer of well known line of high speed and alloy steels. Correspondence invited and will be treated as confidential. Box 707F, Canadian Machinery.

CANADIAN AGENT WANTED — AMERICAN firm whose line (high grade factory specialty) is being manufactured in Canada, wishes to get in touch with live man who will act as Provincial or Dominion representative. Box 679, Canadian Machinery.

Agent Wanted

Wanted, a jobber to represent, in Eastern Canada, an American manufacturer of well-known and advertised line of Oxy-Acetylene Welding and Cutting apparatus. Terms very favorable.

Box 705F
CANADIAN MACHINERY

PATTERNS

TORONTO PATTERN WORKS, 65 JARVIS Street, Toronto. Patterns in wood and metal for all kinds of machinery. (ctfm)

BRANTFORD PATTERN WORKS ARE PREpared to make up patterns of any kind—including marine works—to sketches, blue prints or sample castings. Prompt, efficient service. Bell 'Phone 631; Machine 'Phone 733. Brantford Pattern Works, 49 George St., Brantford, Ont. (ctfm)

Used Machinery Bargains

6—No. 25 Foote Burt Drill presses, $250 each.
1—D-3 Colburn Drill Press, $350.
1—Revell Quadruplex Air Compressor, $500.
1—No. 73½ Bliss Stamping Press, $500.
1—730½ Brown-Boggs Stamping Press, $500.
2—Lees Bradner Thread Millers, $350 each.
1—10,000-lb. Olsen Testing Machine with Extensometer, $500.

All F.O.B. cars Lachine, Quebec, subject to prior sale.

Also Lathes of various kinds and a full line of used pulleys and hangers at very low prices.

Consumers Metal Company
LIMITED
Lachine, Que.

PARTNER WANTED

LIVE BUSINESS MAN TO JOIN ANOTHER in the sale of high-grade electric trucks; clean-cut, profitable business, which will show large returns; this is an exceptional opportunity; executive and selling ability essential; also capital of $10,000; reply immediately. Box No. 720, Canadian Machinery.

FOR SALE

42'' Pond Car Wheel Lathe, Motor Drive, 40 x 40 x 10' Powell, 2 H. Planer, No. 4 Brown & Sharpe Plain Miller, 3-Spindle Barnes B.G. Drill. Box 723F, Canadian Machinery.

USED MACHINERY FOR SALE

1—16" Hendey Shaper
2—18" x 8' Mueller Lathes
1—32" x 24' Engine Lathe
2— 3 x 36 J & L Turret Lathes.

CHARLES P. ARCHIBALD & CO.
Machinery and Supplies
285 BEAVER HALL HILL, MONTREAL

FOR SALE

THE FOLLOWING COKE TIN PLATES IN stock at Toronto warehouse for immediate delivery: 254 packages, 112 sheets, 100 lbs. basis, sizes, 15 x 30, 18¼ x 26¼, 18¾ x 28, 25 x 28, 22 x 26 and 19 x 28, Primes and Wasters. Box 721, Canadian Machinery.

Mr. Charles L. Brown, titular to Canadian Patent No. 203,193, dated August 24th, 1920, relating to Improved Box Forming Machine (Wood), wishes to dispose of his inventor's rights and privileges. For information apply to: Adrian A. St. Laurent, Ind. Eng., Patent Broker, 75 Stewart, Ottawa, Ont. (C18M)

TAKE NOTICE

that the Bennett & Wright Co. Limited of the City of Toronto, Canada, duly manufactured the hot water heater covered by Canadian Patent No. 107,120, prior to the period called for by the Patent Act, and on application to the undersigned any further orders for the above invention will be filled at a reasonable price.

RIDOUT & MAYBEE, 156 Yonge Street, Toronto, Solicitors for Anders B. Reck.
(C17M)

SALESMEN WANTED

Must be thoroughly familiar with the Foundry and Coal Mining Trade. Box 719 F, Canadian Machinery.

MACHINERY WANTED

WANTED IMMEDIATELY—1 30-TON LUCAS Forcing Press. Address all replies to Box 722A, Canadian Machinery.

WANTED—FIVE TO SIX HUNDRED H.P. CORliss engine, also 72 in. roller-band resaw; 250 tons 40 or 50 ft. rails; 5-ton locomotive crane; all must be in good shape. Apply N. J. McArthur, 325 Howe St., Vancouver, B.C. (cfm)

WANTED—8 IN. HORIZONTAL, 54 IN. AND 66 in. upright band resaws; steam engines, 35 to 125 h.p.; 36 in. gang saw grinder, planers, edgers and sprocket chain, etc. R. C. Patterson, Smithville, Ont. (cfm)

Electrical Equipment

WANTED—Circuit breakers, 2-3 phase, 2200 volt, 100 amp., oil switches for pipe mountings with overload release. 1-2 phase same as preceding. Frid Construction Co., Limited, Hamilton, Ont. (cfm)

Machinery Wanted

Advertisements under this heading will be inserted once free of charge. Readers are invited to use this department when in need of equipment. Replies may be sent to box number, care of Canadian Machinery, if desired.

MACHINE WORK WANTED

MACHINE WORK WANTED FOR LATHES, shapers, milling machine and planer, etc. Hourly or contract basis. Prompt delivery. W. H. Sumbling Machinery Co., Toronto. (ctfm)

HARDWARE AT REDUCED PRICES.

Some Interesting Examples of Bulldozer Work

The Uses of a Bulldozer Are Explained, and Four Typical Examples of Work Performed Are Shown—Mechanics Should Become More Familiar with the Possibilities of Such Machines.

By J. H. MOORE

BEFORE going into a discussion of the uses of a bulldozer, and examples of work performed on the same, we will imagine that there are readers who have never watched such a machine in operation. This may appear, to those who are familiar with a bulldozer, like explaining the A, B, C's of the alphabet, but one must remember that many a good mechanic has never entered a forging department, therefore has had no chance to watch the bulldozer perform. It is for the benefit of such readers that we append the following.

Study Fig. 1, not with an idea of looking at the die, but at the machine itself. This view illustrates the main essential working parts of a Williams and White bulldozer. To be brief, this style of machine is used for all types of bending of both hot and cold metals. It consists of a heavy cast iron, or semi-steel bed, with a block or bolster at one end. This block is stationary. The other end has a moving head which slides back and forth on the bed. This head is clearly shown on the photograph. In operation, heavy dies are clamped against the stationary bolster, and on the moving head. These dies are so made that when the moving head comes up to its extreme stroke the form left between the two dies is exactly the desired shape.

The cold bending of course is limited to partly light stock, while very heavy stock is first heated by furnaces in close proximity to the machine. The material is placed on or in the stationary die, when the moving head is back as far as it will go. The operator then pushes his clutch lever, as shown on the photograph, the clutch is released, and along comes the moving head, or ram as it is termed, bending the material as it comes.

This description will no doubt be sufficient to allow readers to grasp the object of such machines. It might be well to add that they are built of extremely strong design and can withstand very hard usage.

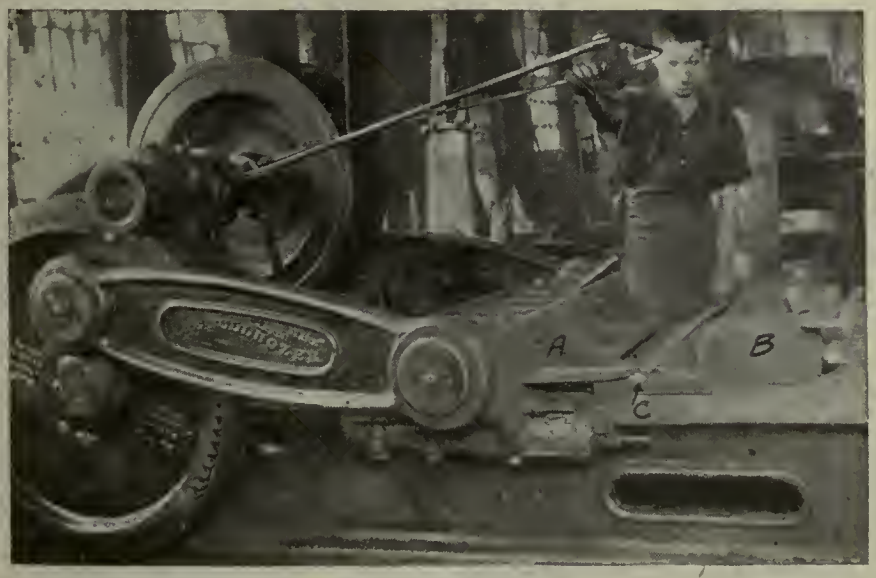

FIG. 1—GENERAL VIEW OF A BULLDOZER, WITH EXAMPLE OF WORK PERFORMED.

FIG. 2—A SPREADING OPERATION. THE STATIONARY PORTION OF DIE ONLY IS SHOWN.

For Forge Shops

The feature as spoken of above makes them ideal for forge shop work, and at the plant of the International Harvester Co., Hamilton, Canada, where these photographs were taken, a great number are in use for all styles of bending. A typical example is that shown at Fig. 1.

The part being bent, or formed, as some express it, is a portion of a harvester. The piece in its finished condition is shown resting on top of the stationary bolster B. The work, before being formed, is illustrated at C. It will be noticed that in this case the work is placed flat on the stationary die, and by close inspection of the photograph the path which the metal will take to fit the die can be followed. A is the moving die. The stock in this case is about 2 inches wide and ½ inch thick. It is first heated, then placed on the die. Near the end of the stock, closest to the line of vision on this photo, is a hole. Advantage is taken of this fact, and the hole is slipped over a gauge pin to prevent the stock moving. This is at the

FIG. 3—A SQUEEZING OPERATION PERFORMED ON BULLDOZER.

end C. The operator pushes the handle, along comes the ram, and a perfect bend is the result. Twelve hundred of these parts are bent in one day.

Spreading Operation

At Fig. 2 is shown a very different style of bulldozer work. A represents a guide for the moving die. We do not show this moving portion as it would conflict with the rest of the view, but its shape can be understood from the nature of the work performed. C represents the part before bending, or spreading, while B shows the finished work.

This piece is made from the U-shaped stock as shown, and the work is gauged from the slot. This is an operation which would be very awkward to perform but for the bulldozer, and when we mention that 300 are completed every nine hours, it speaks well for the efficiency of the operation.

A continuation of the idea is shown at Fig. 3. This illustrates not a spreading but a squeezing operation. Small trunnion supports fit in between these parts, a pile of which can be noticed at right of the photo. After leaving the operation depicted at Fig. 2, the parts are drilled, then passed on to the bulldozer at Fig. 3. Here the operator picks up a trunnion, which has two small pine-like projections on it, and slips these into the two holes at top of piece as shown at A. He now places them in the stationary die, and sets the moving ram in motion. Readers may imagine that the rectangular-shaped nose shown on photo is really squeezing on the piece B. This is not the case, as the nose is really a holding down member and passes directly over the work B, while the die portion of the moving ram comes up and squeezes the work directly to the point where the trunnion pins come through. This might really be termed an assembling operation as the work is all cold. Incidentally it has proved much faster than the old hand assembled method.

Typical Bulldozer Die

The remaining illustration, Fig. 4, is shown more with an idea of presenting the appearance of a complete bulldozer die. C represents the moving die, while the two rams A are attached to this die for guiding and holding down purposes. This system is often adopted to hold the stock securely to the stationary die while being bent. The two portions B are merely housings for the rollers under which the rams A pass. On close inspection of this die a guide pin can be seen toward the left-hand side of the left ram A. D is the stationary die. Another gauge pin can be noted between the two rams A, and somewhat nearer the right hand side.

There are of course more intricate dies made which give a side, and even an angle, motion of separate dies, but for the purpose of this, the first, article on bulldozer work we have touched only on the dies of simpler design. At some later date we will present more intricate problems in buldozer practice.

MOLYBDENUM IN STEEL MAKING

A prominent American metallurgist states that ferromolybdenum is added in a fixed condition. It is supposed to give the steel properties similar to those of tungsten steel, but only one-third to one-half as much molybdenum is necessary; that where regular, high-speed steel contains 18 per cent. tungsten, 6 to 9 per cent. of molybdenum may be substituted. However, it gives these properties only when the addition is properly made and proper heat treatment follows. The regulation of these factors caused so much trouble and expense that, in the United States, the manufacture of molybdenum high-speed tool steels has been practically discontinued for several years. It is used for this purpose in other countries, however, to a considerable extent. At the present time it is mainly employed in tool steel as an auxiliary rather than as a major constituent. Various reasons have been assigned for the discontinuance of the use of molybdenum.

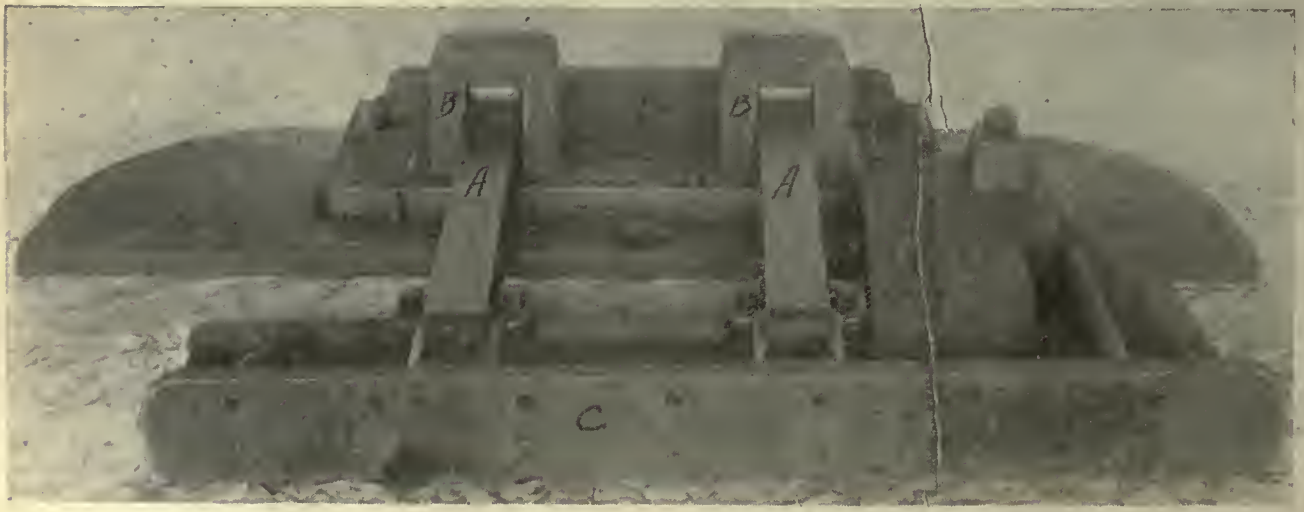

FIG. 4—A GOOD EXAMPLE OF A TYPICAL BULLDOZER DIE.

How One Shop Maintained its Margin of Profit

It is Not Often We Get a Chance to Print Such Experiences—Contract Work is at All Times a Peculiar Proposition—How Certain Work Was Completed is Told Herein

By DONALD A. HAMPSON

CONTRACT work is like job work in one respect—the margin of profit is so small that it keeps the engineering and production heads constantly on the alert to turn defeat into victory. The way one shop maintained its small margin of profit is told herein and the several instances may present ideas which others can use in their business.

For years it had been a struggle to get castings when we wanted them, and as we would like to have them. The congestion in the grey iron foundry business was so bad that we were obliged to make anything go that we could, even if we had to spend money to re-make the parts after they left the foundry. One great trouble with foundries in general is the lack of attention a casting gets after it is poured. The place is pretty hot by the time pouring starts and the men want to get home as soon as that part of the work is completed which takes any skill. This is where a big mistake is made. Hundreds of dollars worth of spoiled castings could be saved if an intelligent, skilled man were left behind to knock apart the moulds, but the general practice is to have Tony or Mike, the watchman, knock out the castings as soon as he comes on the job, and this he proceeds to do in a heroic manner that leaves all castings in the same state—uncovered, and supported in a still red state, by whatever part may happen to rest on the floor, regardless of how the casting will warp and sag in cooling.

We were building a number of machines that had a "track" that was planed to accurate dimensions. It was the hardest piece to machine we had, because of its length and the inside facing of rows of pads sunk below the general surface. This latter was made worse if the castings were warped, so that the pads cut almost through at one place while barely cleaning up at others. Cautioning the foundry did no good. They were supplied with a straight pattern and requested to be careful about the cooling, but all to no avail, and we continued getting castings that would not clean up.

To make these go we heated them red at the sections of bend, weighted them in various ways, and let them cool off. By so doing we were able to get very straight castings and turn our work out with no delay. A casting so weighted is shown at Fig. 1, which illustrates one "symmetrically crooked"—merely having dropped at the ends.

A Talk on Threading

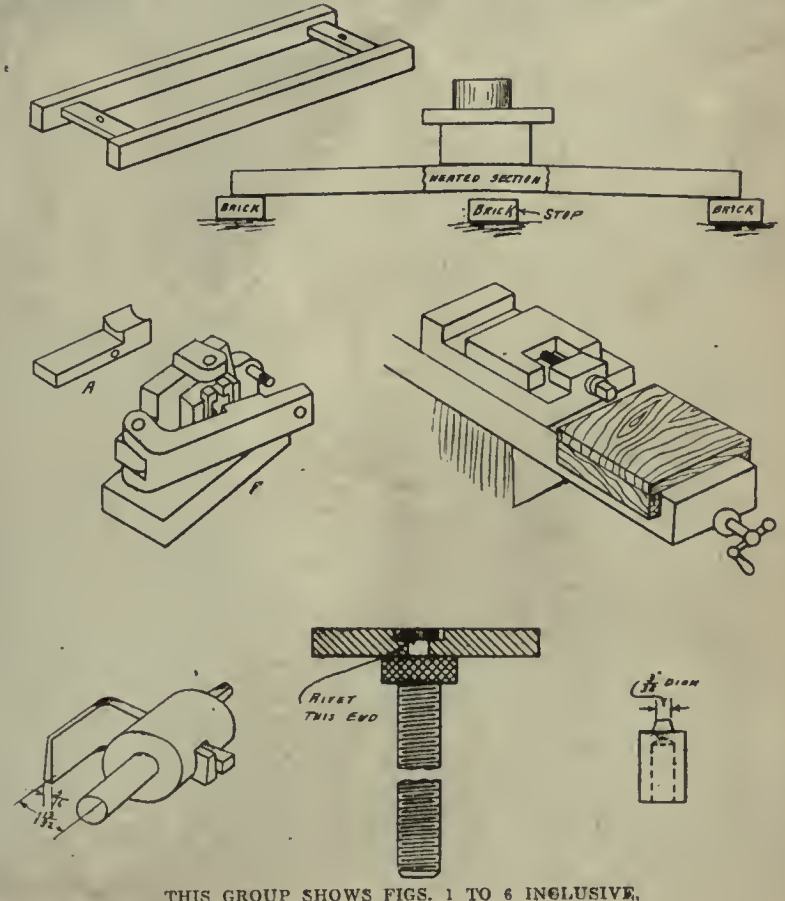
Shops that have to do accurate threading on screw machines or threading machines have been troubled in maintaining a constant lead and in getting a good thread at the end where the die starts. Workmen and executives are apt to think their results and their tools are not as good as those used in other lines and to wonder just how these favored people turn out this perfect work. For instance, they ask, "How do tap makers get such good threads clear to the points of their taps?" The answer is simple. "By selection." Tap blanks are all made up as plug, or bottom, taps and threaded as such. Then an inspector goes over the run and picks out those of poor lead and with poor threads at the start; the good ones are fluted and relieved as plug taps, the poorer ones are cut into taper taps. It is commercially impossible to maintain the production of threaded parts to the highest standard and some such scheme as mentioned saves money without sacrificing needed accuracy. Our shop was making an automotive part on contract, including a screw that was exceedingly hard to keep in shape right up to the end. Our equipment was of the very best. The way we did the work was to set the automatic to make an extra ¾-inch of length and by another operation to cut this part off afterward, it being the only part that had threads that were not acceptable.

Ball Bearings

Our milling department was up to the latest wrinkles in steels and feeds and speeds. Contract work has to be forced where there is clear going. This forcing wears the shoulders of the feed screws and the seat that takes the thrust. It means constant re-facing and collaring. We decided to settle that job once and for all. Each machine, as it was taken out of service for any repairs whatever, was disassembled by removing table, screw and saddle bearing of the screw. Enough material was cut away to permit the insertion of a standard ball thrust bearing of the three ring type, costing around a dollar apiece. Putting this bearing between the shoulder and the cast iron bearing placed all the thrust load on hardened parts. It settled our problem then and there, at very little expense. The first of the millers so changed has now been in daily service for eight years and there is not yet enough wear to make repairs advisable.

Rapid Facing

A customer decided on a change on a dozen presses we were making, substitut-



THIS GROUP SHOWS FIGS. 1 TO 6 INCLUSIVE.

ing a solid 3-inch square steel bar for the cast head piece that was intended to go between the uprights. We got the steel and sawed the bars off, 24 of them in all. As they had to be individually fitted and everyone knows what an uncertain job vertical planed cuts are, we cast our eyes on milling machine equipments that would do the work better and quicker. The photo shows what we found and how it was done. A knee with tongue to fit the table slot was used for both a stop and to align the bars. A single clamp sufficed to hold the work in place. And the inserted blade end mills that we had made to screw directly on the spindle nose for various surfacing jobs were just the proper tool for this work. With plenty of power, we left the sawed pieces long, avoiding any loss through a crooked cut, and let the cutter "walk right through the end," as the chips will show.

The piece shown in Fig. 2 is one of a pair used as a split nut in some ten thousand patented devices we contracted to make. It is made of cold drawn steel ⅜-inch square, milled to shape. The half round cut was made with a formed radius cutter, doing the work in a hand milling machine with lever feed, milling one piece at a time. Though production was acceptable, the finish was not, the tendency being to crowd the work past the arbor, springing the latter and leaving the cut shallow and rough. This resulted in slower tapping and broken taps.

A better scheme was worked out as shown at B, Fig. 2. Two pieces at a time are held in a drilling jig, upright, spaced properly and clamped by the hinge. Then a three lip twist drill is passed down through the bushing and cuts the concave in both pieces at once. Greater production and real uniformity resulted at once from this improved fixture. In general, it might be said that outside of manufacturing shops, the advantages of three or four lip drills and the possibilities of drilling vs. other methods are rather overlooked.

Keeping the Miller New

The best practice in milling and planing is to set up jobs at different points on the table—not to set each and every one right in the centre—but nine out of every ten workmen cannot be taught the wisdom of this. This continual centring wears the ways in one short section (for cuts are rarely of capacity length) and it results in uneven wear and abuse of the table. Workmen have a propensity for dropping hammers, wrenches, and miscellaneous junk on the exposed section of the table between the job set up and the front end—they never put them down carefully. In consequence, that section looks decidedly second-hand in less than a month, and no good end has been accomplished from this malpractice. We found it almost impossible to break the men of this habit so, as it is more convenient to keep tools near by, we made up the protection boards for each machine and the men took to them at once. By making the sides a tight fit on the table, the boards hold themselves in position in spite of jar of cutting. If no other good were accomplished, the feeling that the machines were not abused would compensate for the little effort expended. Fig. 3 shows this kink.

The drawing Fig. 4 illustrates an assembly of a screw set into a head piece, and the teat end riveted over upon a washer in the counterbore, the combination forming a screw that could be turned when desired, but held without an excess of side play. We had been riveting over the teat by hand and we knew all along that we were not getting good work—fully half of the screws were so tight that they had to go through a long loosening process or else they were so loose they had to be sent back, with risk of incurring trouble No. 1 the second time.

The simple fixture shown by the photo is the way in which we turned out a product that "looked as if it was made somewhere." The head piece may be seen under the arch of the fixture, and the lower end of a screw appears below the clamp. This clamp is a bar of steel bent at right angles, the short end having a jaw that holds the screw in a channel, and the long end forming the handle which the boy grasps in connection with the stationary bar, which is nearby; pressure sufficient to keep in place is thus afforded, while as soon as the hand is taken away the work may be removed. The arch shaped main casting is fastened to the drill press table when located by the spindle, fitting in the top and extending up to the taper and tang end, which is driven by the machine spindle. The lower end of the work spindle carries the roller, which "rolls" over the screw end. Production was increased four-fold and the rejects became practically nil. By giving the head a spin with a finger, the boy knows when it still needs more, which he applies by another pull on the feed lever and another trial up to the point where the head will not spin but will push.

Trepanning Tool

After we had built and delivered several cold heading machines to the wire company's new plant, they wanted a change made that involved cutting two three inch holes through the side frames of each, a distance of two inches. The machines had been set up but as yet there was no power in the building and so we had to resort to hand methods—and in these days hand methods have to be arranged for the easiest possible working.

First we put ⅝-inch holes through in the centre, using a common ten-inch ratchet. Meanwhile we were making the trepanning tool shown at Fig. 5, which was to be piloted by the ⅝-inch hole and was to cut away a chunk three inches in diameter. And this it did quite nicely, using the same ratchet with a pipe extension on the handle. Our experience in cutting tank and boiler plates led us to adopt this method as the best and in preference to a series of smaller holes to be finished with a larger tool.

Spotting Bearings

Go into any garage and watch a man scraping a bearing. His can of Prussian blue is in constant use. In fact, the garage machinist would not know how to fit a bearing if he did not have this material. But a little Venetian red or vermilion powder mixed with oil will do as well. The old school of machinists who had to go miles from the nearest habitation on a repair job never had any Prussian blue—they used a little red lead or red paint or lamp black—anything they could find after they got there—and they did good work with it too. Really, a marking material is not essential ex-

REFERENCE TO THE TEXT WILL EXPLAIN THESE PHOTOGRAPHS.

cept on the finest class of work for the bearing spots always show up a visible black or polish that is sufficient. And lamp black is as good a marking material for fine work as any compound that can be bought, and much cheaper.

Concrete Cams

We had a four inch Cleveland automatic and often set it up for as few as a hundred pieces. On several occasions we required feed cams that we did not have and to avoid the expense and delay of these large pieces, we made concrete cams. These served quite nicely. After the machine had been set up in other particulars we would lay out the feed cam in chalk and lead pencil directly on the drum, which was something like three feet in diameter. By turning over the machine and checking the movements we assured ourselves as to the accuracy of our work. Then a strip of 1-16-in. x ¾-in. steel would be bent to follow this contour and wired in place, standing on edge of course. A sheet of wrapping paper would be cut and stuck to the face of the drum to cover the screw holes. Two or three cam screws were greased and inserted to the usual depth, their function being to anchor the cam-to-be. Then using sections of pasteboard for the exterior of the "form," cement was poured (or rather trowelled) on; the procedure being to put the cement on top, cover with pasteboard at the right thickness, fasten the latter securely, and turn the drum until a further portion was on top. The work was left overnight to harden. The resulting cam was solid and secure and had a smooth steel roller face. In point of expense it was highly satisfactory.

Something About Burrs

It is impossible to wholly avoid the process of removing burrs, but in so far as drilled and tapped holes are concerned, two simple means are at hand to avoid this work. Many reamed holes have set-screw or oil holes intersecting them or are intersected by unimportant holes. These unimportant holes should be drilled after the others but before the main holes are reamed, and the tap holes should be tapped before any reaming is done. Then when the reamer is put through, the finished hole is smooth and does not have to be hand scraped or again reamed for the swell that the tap would leave.

The practice of countersinking all holes should be followed; it is a saving of time always, general impressions to the contrary notwithstanading. For ordinary holes a touch is sufficient to remove the burr for tapped holes, they should be countersunk up to or slightly over the outside size; the saving in time and in files will make up for the extra operation. Apprentices trained in the Brown and Sharpe plant are taught early to countersink all holes.

During the war we had a contract that included hundreds of thousands of parts shown by Fig. 5 which were made on the automatics, heat treated, and assembled. The vital part is the little extension, or teat, which had to be hard to resist constant blows without any change of shape, but not so hard as to break or shatter. We had assumed that case-hardened machinery steel would answer the requirements, but tests on the first few thousands proved to the contrary. The few that were strong enough to stand the racket were so hard that they cracked off at the shoulder; the rest, though hard by the file test, battered up in a short time because of the soft interior. The parts had been heated for about 24 hours.

We knew that we could get results by using tool steel, hardening, and then drawing to the proper temper, but this latter material was too expensive both in first cost and in treatment throughout the cutting and tempering. And the proportion of "lost" parts was sure to be greater.

After some trial, we arranged the work satisfactorily. The same machine steel parts were used but they were put through a continuous run of 48 hours in the furnace before quenching. They came out glass hard, of course, but in addition the depth of case went clear through the teat. And the adjacent face of the shoulder was deeply hardened, its state being such that there was no strain at the line where it joined the teat. The parts were hard enough on the surface and far enough under the surface to give the desired backing. They had only to be "let down" to take out the "snap" and become ideal for the work.

The carbonizing transformed the entire end into tool steel at a lesser cost and was then tempered as tool steel would have been. In not a few cases this same process may be followed to advantage; it is reported that a famous file company was short on a certain "shape" and bought three tons of mild steel at 2 cents a pound, which they proceeded to bring up to their standard in a similar manner, and no complaint was ever received, nor did anyone suspect what they were getting.

LUBRICATION AND THE GERM PROCESS

The following is a synopsis of a paper on "Lubrication and the Germ Process," by Henry M. Wells and James E. Southcombe, M.Sc., read at the British Association meeting:

The authors draw attention that the modern view of lubrication on the physico-chemical side is the existence of a residual valency or affinity between the oil and the solid surfaces of the bearing and journal. The problem has, therefore, to be considered as a kind of intimate relationship between the oil and the metal. This is quite a different view to that held by investigators in the past, who thought that the property of "oiliness" so strongly manifested by fatty oils as compared with mineral oils resided in some particular physical characteristic of the oil itself. The modern point of view has been elaborated recently by a number of students of the subject.

The authors have discovered the reason why the fatty or fixed oils possess superior friction-reducing properties to that of mineral oils. They have shown that this is due essentially to the presence in fatty oils of minute quantities of free fatty acids, which are absent in the majority of mineral oils. In consequence of this discovery they have added small quantities (about 1 per cent.) of fatty mineral or organic acids, which are easily accessible and relatively cheap to hydrocarbon oils. The products so obtained possess remarkably low frictional co-efficients. As an example, the addition of 2 per cent. of common fatty acid to a mineral hydro-carbon oil reduces the coefficient of friction shown by this oil on a friction testing machine from 0.0084 to 0.0052—a diminution of 26 per cent.

By suitably choosing the type of fatty acid to be added to mineral oil, the behaviour of oils in the presence of water and other contaminating substances can be modified at will. It is also shown that the risk of metallic corrosion is even less with these oils than the usual compounded oils, because the latter frequently develops in working notable quantities of free acid.

The principle of making mineral lubricating oils possessing increased frictional properties by adding to mineral oils suitably chosen fatty acids in relatively minute amounts has been patented throughout the world, and has been somewhat fancifully called the "germ process," because the fatty acid is the germ of the idea.

The value of the process lies in that oils possessing friction-reducing properties much superior to mineral oils can be prepared at relatively little extra cost to mineral oils. Secondly, by this means an immense quantity of fatty oil suitable for the manufacture of margarine and other foodstuffs is liberated for the country's needs and substituted by a much smaller amount of commercial fatty acids, which are quite unsuitable for food and are more or less in the nature of a by-product.

Finally, it may enable the lubricating oil manufacturer to produce the highest class of friction-reducing oils from comparatively thin — therefore cheaper — mineral oils, and incidentally this may have the utmost significance to-day, when we are striving to foster and develop the mineral oil production of our own country and the Empire.

ERRATA

In our August 12th issue we published an article entitled "Can We Avoid Grinding Wheel Accidents?" In the third paragraph from the bottom of the last column on page 159 the term "exposure between the flanges" should read "outside the flanges," and not the word "between." The wording used was rather confusing so that we call readers' attention to this matter.

Manufacture of Helical Springs for Heavy Duty

In This Age of Mechanical Design, New Problems Arise Continually in the Use of Springs Demanding the Highest Possible Quality—Herein is Shown an Example of Spring for Extreme Heavy Duty.

By T. D. LYNCH, Research Engineer Westinghouse Electric & Mfg. Co.

SPRINGS of great variety of design and quality have been manufactured from flats, rods, ribbon and wire during the ages past. Some of them have been heat treated before forming, others after forming and still others have had no heat treatment, the high elastic properties being given to the latter by the work done in cold rolling or drawing the raw stock to its finished size.

Early spring making was for the use of buggies and spring waggons, then for clocks, watches, cars, locomotives, etc., and still later for automobiles. To the automobile manufacturer belongs the credit for the development of the superior quality of springs now used in the construction of automobiles. This progress, however, has not been without concentration of purpose relative to both material and treatment and each step has inscribed its mark of success or failure.

In this age of mechanical design, when every ounce of strength is exacted from each member, new problems arise continually in the use of springs demanding the highest quality possible to produce. To meet this growing demand for quality, every phase of spring manufacture must be co-ordinated and carefully processed at the furnace, at the rolling mill and at the spring making plant.

The steel maker has offered his carbon spring steel made in large open hearth furnaces, which has its field of application but is not strong enough for the most severe conditions that must be met at this time. Chrome vanadium steel, silico-manganese steel and chrome molybdenum steel have much higher elastic properties and are capable of withstanding proportionally greater stresses. Therefore, these and other alloy steels must be considered in connection with this high class work.

Springs for Heavy Duty

Within recent months one of the writer's duties has been to assist in the procurement of helical springs for a unique and unusually severe duty. The accompanying photograph shows the general problem involved, which consists in the transmission of the driving power of a motor to the wheels of a locomotive through a set of cushion springs. The arrangement is such as to permit free vertical and lateral wheel play. In this application the stresses are tension, compression, torsion and shear, separately or in combination, and these stresses are augmented from time to time by shock, producing a condition that makes necessary a material of high elastic strength, and, at the same time, a large degree of toughness.

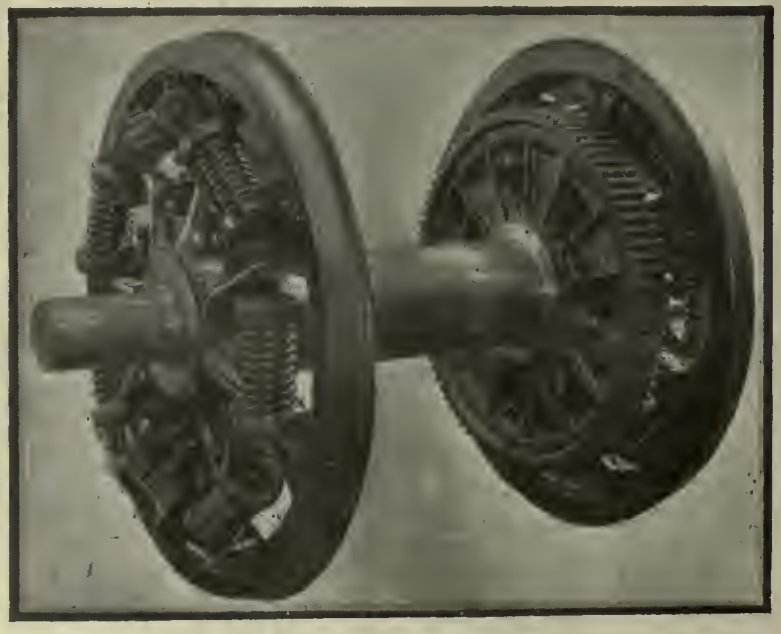
The first step in the study of this problem was to investigate the general practice of spring makers—to find that the general process in vogue for the manufacture of springs from bars larger than 3-8-inch diameter is to obtain the bars from the steel maker, produced in large open hearth furnaces, rolled in a commercial manner, representing tonnage production. Bars thus made are heated to a temperature varying more or less from a bright to a dull red at different parts of their length, coiled into springs and quenched from this irregular coiling temperature. It is needless to say that springs made by such a process cannot be depended upon in severe service.

A few spring makers have realized the need for greater care in making and heat treating springs for heavy duty and a receptive attitude towards better spring making is now being taken by them. Spring steel, and especially alloy spring steel, cannot be too carefully made, nor can it be too carefully coiled and treated in order to produce a strictly reliable finished product. Therefore, let us assume that the steel is carefully made and rolled into rods by the processes known to the steel makers as their best, coiled into springs at a proper and uniform temperature and finally treated by steel treaters under their best practice. Only such manufacture and treatment can be expected to give us the very best results. This hypothesis being granted, let us propose a process for consideration, covering the manufacture of a silico-manganese steel spring made from 1-inch rounds, including the making and rolling of the steel, the coiling, treating, testing and inspection of the spring, in order that we may procure the reliable quality above indicated.

There are many alloy spring steels on the market, any one of which would require similar care in their making and fabrication, but for this article we have chosen a silico-manganese steel. The question now arises how should a spring of the highest quality be processed, including the chemical composition, manufacture of the steel, rolling of the billets and bars, heating and coiling of the spring, the heat treating, inspection and general care required throughout the different steps in order to produce the most reliable product. The following process has been worked out and is submitted for criticism and suggestions from those who may have similar problems to solve.

Chemical Analysis

The steel shall be what is known as silico-manganese steel of the following chemical analysis, both on ladle test and check test from finished rolled



HEAVY DUTY SPRINGS USED ON THE WHEELS OF A LOCOMOTIVE.

bars: Carbon .50-.60, manganese .60-.80, phosphorus not over .04, sulphur not over .04, silicon 1.90-2.20.

The steel shall be made by the crucible or electric furnace process and by a company that has been known to have produced high quality spring steel of the class specified. The ingots shall be not less than 9 inches square at large end and 8 inches square at smaller end, so poured and the molds so coated as to give a smooth surface to the ingot. Each ingot, when cold, shall be carefully inspected and any blemishes shall be chipped or ground out, leaving a surface that will be free from laps or seams after rolling.

Rolling of Rounds

The ingots shall be slowly and carefully heated to approximately 1,100 degrees Centigrade and rolled or forged to squares of approximately 3 inches by 3 inches and sheared into suitable billet lengths for final rolling. Excessive reduction will not be permitted. Sufficient discard shall be made so that no signs of piping or segregation can be found and a very careful inspection made, especially of the top cut.

The billets shall be allowed to become cold and a very careful inspection made for surface defects and any slight blemishes ground out, leaving a smooth, even surface, no ragged corners or slivers being permitted. The billets shall then be heated to approximately 1,100 degrees Centigrade and rolled to finish size, great care being taken to avoid excessive reduction at any one pass.

The bars shall be sheared to length and carefully inspected for piping, segregation and surface defects. Each bar shall be straight, free from surface cracks, scratches, seams, folds and indentations and shall be true to section. The diameter of the bar shall not vary more than two and one-half per cent. from that specified.

All bars shall be tied in bundles and a metal tag securely attached to each bundle. The tag shall have stamped on it the requisition number, heat number, size of rod and manufacturer's identification mark. When bundles are opened great care must be exercised so as not to nick or in any way injure the bars. A nick or scratch in a bar, however small, can not be permitted.

Coiling of Springs

The bars shall be heated slowly to a uniform temperature of approximately 925 degrees C. (1,700 deg. F.) and immediately coiled over a mandrel preheated to at least 100 degrees C. The mandrel shall not be water cooled nor shall any water be allowed to touch the spring while hot.

Notching for length shall be done at a dull red heat and in such a manner as not to cut, scratch or otherwise injure the surface at any other point on the spring. The springs after notching shall be allowed to cool slowly and uniformly in such a manner as to prevent local chilling which may cause surface stresses or cracks to form.

The springs shall be slowly and uniformly preheated to approximately 700 degrees C. (1,290 degr. F.), transferred to a furnace held at a quenching temperature of 900 degrees C. (1,650 deg. F.) and uniformly heated as near as possible to this temperature and quenched in oil. The quenched spring shall be drawn in a salt bath at approximately 455 degrees C. (850 deg. F.) to relieve quenching stresses. The drawn springs shall be cleaned from the adhering salt by a hot soda wash, followed by an oil or lime dip to protect them from corrosion.

Physical Properties and Tests

The properties specified below shall be determined in the order given. The spring shall not be rapped or otherwise disturbed during the test.

Solid Height.—The solid height is the perpendicular distance between the plates of testing machine when the spring is compressed solid with a test load of at least 125 per cent. that necessary to bring all the coils in contact. The solid height shall not vary more than 1.5 per cent. from that specified.

Free Height.—The free height is the height of the spring when the load specified in paragraph (a) has been released, and is determined by placing a straight-edge across the top of the spring and measuring the perpendicular distance from the plate on which the spring stands to the straight edge, at the approximate centre of the spring. The free height shall not vary more than 1.5 per cent. from that specified.

Loaded Height.—The loaded height is the distance between the plates of the testing machine when the specified working load is applied. The loaded height shall not vary more than 1.5 per cent. over nor more than .75 per cent. under that specified.

Permanent Set.—The permanent set is the difference, if any, between the free height and the height (measured at the same point and in a similar manner) after the spring has been compressed solid three times in rapid succession with the test load already specified. The permanent set shall not exceed .4 per cent. of the free height.

Hardness Tests.—The Brinell hardness number shall not be less than 375 nor more than 450. This test shall be made on the coupon resulting from notching to length and broken off after spring has been heat treated.

Structure.—The grain structure of the finished spring should be troostitic or troosto-sorbitic.

Dimensions

The springs shall be straight, with uniform pitch, and shall remain straight throughout the working range. The diameter of single coils of the spring shall conform to the tolerance given on the drawing. The concentricity of the coils of the spring shall be determined by means of a plug-gauge and ring-gauge, extending the full length of the spring, "D" is specified outside diamesions:—

	Length of Spring			
	10" or less		Over 10"	
Outside diameter of ring gauge	d minus	.063	d minus	.094
Inside diameter of ring gauge	D plus	.063	D plus	.094

where "d" is specified inside diameter of spring. "D" is specified outside diameter of spring.

When the drawing specifies a spring with ends squared and the spring is placed with either end on a flat plate, its axis shall not make an angle of more than 5 degrees with a perpendicular to the plate.

Springs varying from the required finished dimensions may be reheated and reset but all such reset springs shall be completely re-treated—that is quenched and drawn again.

Tests and inspection shall be made at the end.

Packing and Marking

All springs shall be plainly marked with serial numbers and manufacturer's identification letter at one end of the finished spring and on each coupon resulting from notching to length. The purchaser shall assign the serial numbers to be used with each order. Each size of spring shall be packed separately in such a manner as to protect the springs from injury during shipment.

Each package shall be plainly marked as follows:—Requisition number, P. D. Spec. No., number of springs, style number of spring (or drawing and item number if there is no style number), name of manufacturer.

For example:—Req. C-5,100; P. D. Spec. No. ; 6 springs; style No. 591,500; Blank Company.

Tests and inspection shall be made by the purchaser at the place of manufacture prior to shipment. The inspector representing the purchaser shall have free entry at all times while the contract of the purchaser is being performed to all parts of the manufacturer's works which concern the manufacture of the springs ordered. The manufacturer shall afford the inspector, free of cost, all reasonable facilities to satisfy him that the springs are being furnished in accordance with this specification.

This paper has included more than the heat treatment of springs and is intended to emphasize the great importance of a better knowledge of complete spring manufacture and bring together on common terms the designing engineer, the steel maker and the spring maker.

A full discussion of this article is desired, hoping that the combined experience of the members of this organization or others may bring out additional data that will assist in establishing a complete and efficient process for the manufacture of truly reliable springs for heavy duty. It is further hoped that this paper has shown the need of coordinating the talent and experience of the men at the steel mill, rolling mill and spring coiling plant as well as the heat treating and testing of the finished product.

Conley Continues Along the Road of Experience

John's Trials Are Varied—He Performs a Bit of Dentistry, Spoils a Job, Then Finds Out Why He Spoiled It—He Hears of the Peculiarities of Cast Iron, Etc., Etc.

By J. DAVIES

AFTER John had been in the shop for six months his father said jokingly to him, "I suppose you have learnt all there is to learn in the shop by this time." To which John replied, "Not much. I have just been in the shop long enough to find out that I don't know anything."

"If you have found that out in six months you are making pretty good progress. It takes some men six years to find it out and some never do. What have you been doing to-day?"

"I have been doing a bit of dentistry to-day. Some teeth were broken out of a lathe gear and I had to put some fresh ones in."

"How did you manage it?"

"Mr. Smith had the fragments of the broken teeth chipped out, and the spaces filled up with the oxy-acetylene welder, then acting under instructions I bolted the gear against the angle plate and marked around two of the teeth on the angle plate. I next ground a tool to fit one of the spaces I had previously placed at the top. I now put the tool in the tool post, fitted it correctly into the space, and tightened it up firmly, setting the indicator for depth at zero.

"I next loosened up the job and turned it round until the broken part came under the tool, and two of the good teeth coincided with the marks I had put on the angle plate. All I had to do after this was to feed the tool down to the zero mark, which indicated the depth, and repeat the operation as many times as there were teeth to be replaced."

"That sounds pretty good, but how did you know that you were moving your job round in a true circle?"

"Oh, I forgot to mention that the boss had the surplus metal turned off in the lathe, and had a piece of flat iron bent at right angles bolted against the angle plate for the gear to rest on. I thought I did that job pretty slick but the next job, oh, boy!"

"What happened to the next job?"

"Well there is no use mincing matters, I completely spoiled it, and I don't hardly know yet how I did it."

'That sounds interesting. What kind of a job was it?"

"It was a cast iron block. I had to put a 60 deg. dovetail on each side, and make it to fit a female gauge. This was the first dovetail that I had ever done. The first thing I did was to put the head of the shaper round until the 60 deg. mark coincided with the zero, then I tried to cut the dovetail but I found the tool rubbing hard on the back stroke and when I tried the 60 deg. thread gauge on it it wouldn't fit within a mile. I moved the head to a different angle, and by the time I made the work fit the gauge, I had it too small. I must confess I was completely up a tree, and now the job is resting on the scrap pile waiting for a cheap trip to the cupola. What was the trouble, dad?"

"The first difficulty, my boy, was in misunderstanding the graduations on your machine. The machine was at zero when your cross and vertical slides were at right angles to each other. Nearly every shaper and planer that I have seen is marked this way. It is apt to be very confusing to a beginner, consequently when you wanted an angle of 60 deg. with the horizontal, you had to move your head 30 deg. because you were already set at 90 deg.

"Your graduation would now read 30 deg. which does not mean that you would cut a 30 deg. angle, but that you have moved your head 30 deg. from the vertical, which would be 60 deg. from the horizontal. It doesn't follow that after your machine is set to the correct angle that you are going to cut that angle. It is quite possible to cut a right angle and have your machine set for a 60 deg. angle."

"How do you make that out?"

"The shape of your tool has a good deal to do with it. Suppose you had your shaper head set at 60 deg. and the cutting edge of your tool was vertical to your work, you would make a right angle because in that case you couldn't make your tool cut any other than its own shape. In every case of dovetails or undercuts you must be sure that your tool is a smaller angle than the one you desire to cut.

"It will help you to understand angles if you get a common two-foot rule, place one 12-inch length on top of the other and open it out to form a square. Remember that you start at 0 and keep increasing your angle to 90 deg., when your rule will form a square. If you continue in the same direction until you have straightened out your rule you have increased your angle from 90 deg. to 180 deg.

"To avoid the tool dragging on the back stroke, it is necessary to move your clapper box so that your tool will lift away from the work. Before starting a cut always lift up your tool by hand to see that it lifts away from your work. If you were cutting a slot for the head of a bolt you would not be able to move your clapper box. You would have the choice of two alternatives, either lengthen your stroke so that your tool could be run clear through the slot and lifted up at one end and put down at the other, or the tool and clapper box could be fastened rigidly so that they could not move at all.

"I once saw a fellow with an ingenious device for this kind of work. He had a common door hinge clamped to the back of the tool in such a way that it would bend on the forward stroke and when the tool got past the end of the slot it would fall down and on the return stroke lift the tool clear of the slot."

"Thanks, very much, for your explanation, dad. I see the idea clearly, no wonder I spoiled the job."

A short time after John had this conversation with his father, he was promoted to the planing machine, and as the shaper and planer are so near akin we will omit any further reference to the shaper and follow him to the planer.

When he was running the shaper he had often looked with envious eyes at the planer hand riding on the end of the table with his legs dangling down. Now that John is running the planer he is keen to do the same thing himself the first chance he gets.

It so happened that the first job he had was one with a fairly long stroke. John perched himself up on the end of the table and started to kid the other fellows and do all in his power to make them jealous of his soft snap as he termed it, but unfortunately for John the dog on the side of the table which operates the reverse slipped, and before John could grab the wrench and tighten it up, the table had run off the rack to the delight of those around. John naturally came in for some chaffing, and he had hard work to organize a crow bar gang to put the table back in its place, which he was anxious to do before the boss came around.

He was planing a surface plate, and he had received instructions to just rough it out, then take it off the machine, put it on one side, and go on with something else. He didn't understand why he was not to finish it when he had it set up, so he decided he would ask the boss the reason. So when Mr. Smith came around, John, pointing to the casting, asked him why he had had that casting taken off the machine before it was finished.

Mr. Smith replied: "It is like this, John. Cast iron is subject to more or less change of shape, particularly after the outer surface, or skin, has been removed, by turning or planing. One method of avoiding these changes in the finished part is to allow the castings to "season" or stand for several weeks or even months after taking the roughing cuts, before finishing them. These changes are caused by the internal stresses in the casting, which are

gradually readjusted and neutralized by seasoning.

"Sometimes in order to avoid a long seasoning period, castings that must retain their shape as much as possible are subjected to some kind of heat treatment. A method which has proved successful, as applied to the cast iron beds of measuring machines, is in the nature of an annealing process. After rough machining castings, they are placed in a furnace and heated to a dull red heat and allowed to cool very gradually, then machine finished and scraped.

"Another peculiar feature of cast iron parts which are subject to repeated heating and cooling is that they grow or increase in size. This growth is so pronounced that annealing ovens eight feet in length have been known to grow to eight feet six inches."

"There is another very important thing I want to call your attention to. Few machinists realize how easily a casting, even of very large size, can be sprung by careless bolting down to the table. Before finishing a casting that needs to be machined very accurately, it should be roughed all over as there is a certain amount of internal stress in every casting, and any uneven places at the bottom should be packed up, so as to give a good solid bearing surface before being finally bolted down. Otherwise the work will be bolted down, and when the bolts are released it will go back to its original shape, with the result that the planed surface will not be true.

"Where there is a large surface to be machined, like the surface plate you have just taken off, it could have been roughed out with a gang tool holder. Tool holders are commonly used in most planer and shaper work. They are an advantage, not only from the great saving in tool steel, but from the facility with which the small inserted tool can be removed and ground up to shape. One special form of tool holder, peculiar to planers, is for holding three or four inserted roughing tools. These are called gang tools. It has been found that the resistance of a cut varies as the square of the thickness of the chip, and that a rougher feed can be taken if the cut is divided up among three or four tools than would be possible if only one tool was used.

"Cast iron should be finished with a broad flat tool unless the metal is very hard and causes chattering, when the breadth of the tool will have to be somewhat modified. In roughing out cast iron it is sometimes advisable to take a cut with a chisel along the edge, where the tool leaves the work, to prevent it breaking away and leaving ragged edge, but, look, it is 11 o'clock, and time for bed, so off you go, we will continue this discussion later."

Optical Reflecting Power of Nickel and Monel Metal

SOME recent tests of the U.S. Bureau of Standards are of interest in connection with the use of nickel and Monel metal for the construction of mirrors and of reflectors for automobile and locomotive headlights, for searchlights and other similar equipment. The tests show that polished surfaces of both metals reflect a high percentage of light, and greater than most other metals as is indicated in the following table containing the results of reflectivity tests.

Metal	Authority	Per Cent. of White Light Reflected
Nickel	Bureau of Standards	65
Monel Metal	Bureau of Standards	62
Silver	Smithsonian Physical Tables	92
Gold	Smithsonian Physical Tables	65
Speculum Metal	Smithsonian Physical Tables	62
Platinum	Smithsonian Physical Tables	61
Steel	Smithsonian Physical Tables	55
Copper	Smithsonian Physical Tables	55
Nickel Bronze	Rubens and Hagen	49
Tungsten	Coblenz	50

Due to the fact also that nickel and Monel metal are not corrodible metals a polished surface of either will retain its polish and reflecting power and will not become dulled and less efficient upon exposure to air and moisture as surfaces of other metals will.

These valuable properties of nickel are most commonly utilized at present in the form of nickel-plated reflectors and it is in this form that most people are familiar with them. Much interest is being manifested, however, in solid nickel and Monel metal reflector construction, i.e., in reflectors constructed of formed nickel or Monel metal.

Optical Emissivity of Nickel and of Monel Metal

In order to determine the temperature of an incandescent mass of any metal in the open with an optical pyrometer such as that of the Leeds and Northrup Company, or the Scimatco, it is necessary to know the radiating or light emitting power of the metal; namely, the emissivity or the ratio of the light emitted by the metal to that emitted by a perfect black body at the same temperature. The metal always appears cooler or darker than a black body, such as carbon or graphite, at the same temperature for it emits or radiates less light; its emissivity is always only a fractional part of that of the former and always less than one.

In consequence of its lesser light-emitting power the temperature of the metal, when measured optically, appears to be less than it really is and the difference between the true and the "apparent" temperature is greater the smaller is the emissivity of the metal. This true temperature may, however, be calculated from the apparent or measured temperature by using the following equation:

$$\frac{\frac{1}{\text{true temperature} + 459}}{\frac{1}{\text{apparent temperature} + 459}} = .0000579 \log E$$

where E is the emissivity and the temperature are in Fahrenheit degrees.

Tests at the U.S. Bureau of Standards have shown that the emissivity of both nickel and Monel metal in the molten states is .38 and consequently almost equal to that of iron or steel. In the solid state both nickel and Monel become covered with a thin layer of oxide when heated in air to incandescent temperatures; the emissivity of solid oxides of nickel and Monel are .89 and .70 respectively.

REGO CUTTING APPARATUS

We have received a very fine catalogue dealing with Rego welding and cutting apparatus. The Carter Welding Co., Toronto, Canada, are sole sales representatives for this line, and to those not familiar with this apparatus we suggest a perusal of the following:

The Rego principle of gas mixture, whereby the acetylene enters the mixing chamber at a slightly higher pressure than the oxygen, is said to positively insure the elimination of the flashback under all operating conditions. It is claimed that it materially reduces the oxygen pressure, thereby preventing any excess and wasteful oxygen, which is detrimental to good welding. Economy of operation, safety and perfection of flame, are other features claimed for this line.

The catalogue shows some actual photographs of tests for flashbacks, and it is clearly shown that there no flashback occurs. The book deals with the carrying-cases, trucks and various welding apparatus. There are also shown some welding and battery outfits, some lead burning and light welding apparatus, and a decarbonizing outfit.

Another item is a description of the Rego torch, with complete data on the same. The various models are shown, and specifications given. The latter part of the book describes tripod manifolds, wall manifolds, and the Rego diaphragm regulator, together with detailed description. Other styles of regulator are shown, also adapters, hose connections, wrenches, etc., etc.

Calculating Dimensions on 100-h.p. H.R.T. Boiler

The Shell and Joint Portions Are Discussed in This Present Article, and in Later Issues We Will Go Still Further Into This Matter—It is a Good Thing to Know the Whys and Wherefores of Boiler Design.

By T. H. FENNER, Editor Power House

IN our October 14th issue we published an article by the above author dealing with the design of joints of the butt strap type. Believing that readers are interested in these calculations, we continue in the present article to discuss the application of the previous joints discussed to the design of an actual boiler.

Assuming that the boiler is of 100 h.p., the leading dimensions being 72-in. diameter, by 18-ft. long, and a working pressure of 125 lbs. per square inch, we have the following:

The first thing necessary to find is the thickness of plate to carry the required pressure, and this is accomplished as follows: It is a well known fact that the bursting pressure of a sphere is found from the formulae below.

$$f=\frac{pd}{2t}$$

When we wish to apply this to an actual boiler, we have some variations to introduce, these being the least percentages of longitudinal joint, and the factor of safety. Neglecting these for a moment, we will show how to find any one of the factors from the others. For instance, to find the pressure the formula would be

$$p=\frac{f2t}{d}$$

To find the thickness we would have

$$t=\frac{pd}{2f}$$

While to find diameter the formula becomes

$$d=\frac{2tf}{p}$$

The formula to find the working pressure of a boiler is

$$WP=\frac{S\times\%\times 2t}{d\times F}$$

where S=tensile strength of material, %=least percentage of longitudinal joints, t=thickness of plate in inches, d=diameter in inches, and F=factor of safety.

We have already set the required working pressure, and as we are to get a boiler of good workmanship and material we can assume 4.5 as a factor of safety. We will use a triple-riveted double-strap butt joint with an efficiency of 86% for the longitudinal seams, so that all that remains is to find the required thickness of shell. We must, therefore, substitute the known figures in the formula, and thus find the unknown. We have then

WP=125,
d=72,
S=60000,
F=4.5,
%=86.

Putting in the figures, we get

$$\frac{60000\times.86\times 2t}{72\times 4.5}=125.$$

It is easier to use all fractions instead of decimals, so

$$\frac{60000\times 86\times 2t\times 2}{72\times 100\times 9}=125.$$

By cancelling out we get

$$\frac{50\times 86\times 2t}{3\times 9}=125$$

$$2t=\frac{125\times 27}{50\times 86}$$

$$t=\frac{125\times 27}{100\times 86}$$

$$t=.3924.$$

The nearest fraction to this is 25-64, but as the plates are not made in variations closer than 1-32, we will call it 3-8 inch and see if that will give the desired result. If not, we will increase it 1-16.

Then

$$\frac{60000\times 86\times 2\times 3}{72\times 100\times 9\times 4}=WP.$$

Cancelling

$$\frac{50\times 86}{9\times 4}=119.$$

This gives only 119 lbs., so we must take 7-16 as the size of plate, and try again.

$$\frac{60000\times 86\times 2\times 7}{72\times 100\times 9\times 8}=WP.$$

Cancelling

$$\frac{25\times 43\times 7}{6\times 9}=139.$$

This gives us 14 lbs. more than we require, but as plates in this country are not rolled to dimensions of thirty-seconds of an inch, we must use the 7-16 plate. This is a good fault, as it allows a margin against corrosion, and makes practically no difference to the heat conductivity. It also allows a bigger factor of safety. This will now be, assuming the pressure is carried at the figure first set

$$\frac{60000\times 86\times 7}{72\times 100\times F\times 8}=125.$$

Then

$$F=\frac{60000\times 86\times 7}{125\times 72\times 100\times 8}$$

Cancelling

$$F=\frac{86\times 7}{5\times 24}$$

$$F=5.$$

Designing the Joint

We have now got the diameter, length and thickness of plate of the boiler, and now we will determine the particulars of the joint.

First, as we have seen in the articles on riveted joints, we will determine the pitch of rivets in the outer row. Then

$$\frac{P-D}{P}=.86$$

$$P-D=.86P$$

$$D=.14P.$$

Now we have 7-16 plate, we will have a 15-16 inch rivet, and if the diameter is .14 of the pitch, the pitch will be

$$\frac{.9375}{.14}=6.69 \text{ or say } 6\ 11\text{-}16.$$

Let us see how close this will come to the required percentage.

$$\frac{6.6875-.9375}{6.6875}=85.98\%.$$

This is sufficiently close for all purposes. We will now try the rivet strength, using the pitch found. We

shall have four rivets in double shear and one in single shear, making eight rivet areas in all. Then by formula, using .7 as the constant for steel rivets in steel plates

$$\frac{a \times n \times C}{p \times t} = \%.$$

Then

$$\frac{15 \times 15 \times .7854 \times 8 \times 70 \times 16 \times 16}{16 \times 16 \times 107 \times 7 \times 100} = \%.$$

Cancelling

$$\frac{9 \times .7854 \times 20}{107} = 132\%.$$

This gives a much higher percentage of rivet strength than plate strength. By reducing the rivet diameter to ⅞ inch we get a higher plate strength, and a lower rivet strength, thus

$$\frac{7 \times 7 \times .7854 \times 8 \times 70 \times 16 \times 16}{8 \times 8 \times 107 \times 7 \times 100} = 111.3\% \text{ rivets}$$

and $\frac{6\ 11\text{-}16 - ⅞}{6\ 11\text{-}16} = 86.9\%$ for plate.

This is more in proportion, and the smaller size rivets will reduce the cost of manufacture.

We will now see if we are within the limits of the maximum pitch as allowed by the Ontario regulations. The maximum pitch is found by using the formula

$$PM = (C \times T) + 1⅝$$

where PM = maximum pitch,
C = Constant,
T = Thickness of plate in inches.

The constant C varies with the type of joint as follows:

No. of Rivets in one pitch	Constant for Lap joint	Constant for Double butt Strap joints
1	1.31	1.75
2	2.62	3.5
3	3.47	4.63
4	4.14	5.52
5	....	6.00

As there are five rivets in a pitch, we must use the constant 6. Then

$$PM = (6 \times .4375) + 1.625$$
$$= 2.6250 + 1.625$$
$$= 4.25.$$

Although the regulations omit to state this, in a joint with every alternative rivet omitted in the outside row, this formula should be multiplied by 2, and in this case the maximum pitch for the outside rivets is therefore 8¼ inches, and we are well inside this dimension. The combined efficiency of plate and rivets must be found from the formula given in the regulations:

$$\frac{(A \times C) + (P - 2d)T}{P \times T}$$

This, as can be readily seen, is the shearing strength of one rivet, multiplied by the constant, and added to the net section of the plate between the outside row of rivets, divided by the unit section. Substituting figures we get

$$\frac{\left\{\left[\frac{7 \times 7 \times .7854 \times 70}{8 \times 8 \times 100}\right] + \left[6 - \frac{11}{16} - 1¾\right] \times \frac{7}{16}\right\}}{6 \frac{11}{16} \times \frac{7}{16}} =$$

Combined Efficiency.

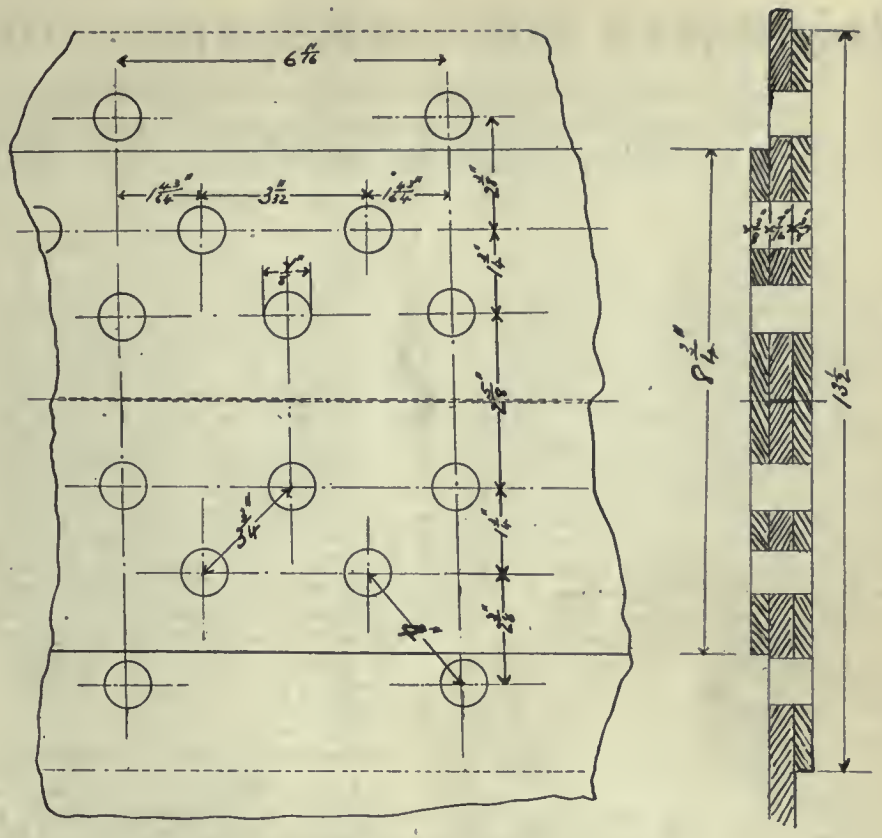
Reducing to decimals it becomes

$$\frac{.42 + 2.16}{2.92} = \frac{2.58}{2.92}$$

$$= 88.3\%,$$

which is higher than the plate strength as determined.

We must now determine the distance between the rows of rivets, and the exact allowable arc definitely decided by the regulations. Of course one could arrive at this distance by calculating the section of metal to be left to secure the necessary strength, but for the purpose of those passing examinations it will be better to work out the formulae set down by the Ontario board. The minimum distance between the outer and middle rows is found by the following expression, where V = the minimum distance:



TREBLE RIVETED DOUBLE UNEQUAL STRAP JOINT.

$$V = \sqrt{[(11\text{-}20P + d)(1\text{-}20P + d)]}$$

In order to make these clear we will show the various steps in full. Substituting figures we get

$$V = \sqrt{[(11\text{-}20 \times 6.6875 + .875)(1\text{-}20 \times 6.6875 + .875)]}$$
$$= \sqrt{[(.55 \times 6.6875 + .875)(.05 \times 6.6875 + .875)]}$$
$$= \sqrt{[(3.6781 + .875)(.3343 + .875)]}$$
$$= \sqrt{(4.5531 \times 1.2093)}$$
$$= \sqrt{5.4793}$$
$$= 2.33$$

Therefore 2.33 inches is the minimum distance between outer and middle rows. For the distance between inner and middle rows we have

$$\sqrt{[(11P + 8d)(P + 8d)]} \div 20$$

Substituting figures

$$\sqrt{[(11 \times 6.6875 + 8 \times .875)(6.6875 + 8 \times .875)]} \div 20$$
$$= \sqrt{[(73.5625 + 7)(6.6875 + 7)]} \div 20$$
$$= \sqrt{[80.5625 \times 13.6875 \div 20]}$$
$$= \sqrt{[1102.69 \div 20]}$$
$$= 33.2 \div 20 = 1.66.$$

Then 1.66 inches is the minimum pitch between the inner and middle row.

For the minimum diagonal pitch between inner and middle rows the formula is

$$P = (3P + 4d) \div 10$$
$$= (3 \times 6.6875 + 4 \times .875) \div 10$$
$$= (20.0625 + 3.5) \div 10$$
$$= 23.5625 \div 10 = 2.35.$$

Relation of Fuel and Furnace to Heat Treatment

Technical Appellations Are Avoided as Much as Possible—Principal Fuels Used Are Discussed, Also Furnaces and Burner Nozzles—This Article Should Be Read by All Interested in Heat Treatment.

By R. P. MAYNARD *

IN dealing with this subject it is not the purpose of the writer to avoid in so far as is possible any technical appellations, and to refrain, moreover, from reference to any commercially advertised appliances, such as furnaces and burners of which there are legion. My vocation brings me in intimate touch with the heat treatment of steel in all its many phases and in shops utilizing appliances from the most modern to the crudest makeshift. In the course of this constant contact with the steel treater, I find that he is invariably well trained in the handling of both high and low carbon steel, and possesses almost infallible knowledge of the requisite textures, grain and lustre of the metal in all its varying degrees of carbon content, and that, while he is aware that heating is the most important of all the operations to which steel must be subjected, still I find that in the majority of cases he is grossly ignorant of that which makes the heat possible—namely, fuel application.

Besides the steel, there are three other prime elements involved in its treatment, which are (1) furnace; (2) fuel, and (3) operator. The latter is often like the average automobilist, whose knowledge of his car extends only to the hood and footboard. It is my intention to convey henceforth a brief discussion of combustion and its application, augmented by a few criticisms of what is hoped will be of a constructive nature.

The principal fuels used in heat treating are bituminous and anthracite coals, coke, fuel oil, natural gas and gas manufactured from solid or liquid fuels. These fuels consist of combinations of carbon, hydrocarbon and hydrogen, which, when combined with oxygen at certain temperatures, unite and form a combustible mixture. The source of oxygen is, of course, the air, and the more intimately it is mixed with a given fuel, the more efficient the combustion derived.

Fuels Used

Solid fuels are gradually being displaced for heat treating by liquid and gaseous fuels, with the latter, gas, predominating, principally because of its cleanliness and convenience. Of all the available fuels used commercially, gas is the only one which the steel treater does not have to handle, store and distribute, and is, moreover, unique in that it is not paid for until after being used.

Most gas companies maintain a corps of trained industrial fuel engineers, whose business it is to assist the steel treater in his heating problems, and it is partly because the oil companies do not offer this engineering service that this splendid fuel is not in more general use for the heat treatment of steel. Properly burned, the use of oil affords a marked economy, especially when used in connection with the larger furnaces, for in the use of oil the heat treater is simply operating miniature gas plants, as the liquid hydro-carbons are expanded into a gas and united with oxygen to produce heat. To burn a given quantity of oil requires the same amount of air as is required to burn the equivalent heat value of gas. The luminosity of the flame is due to the carbon content of the fuel, which insures a soft reducing furnace atmosphere, thus eliminating the possibility of scale.

Must be Thoroughly Screened

To properly burn a liquid fuel requires that the oil be thoroughly screened, as no oil burning system can burn oil that is not clean. The liquid must then be as finely divided as possible, and while in this atomized state must be mingled with the proper amount of air to support combustion. The liquid hydro-carbons can be finely divided by several methods. Air at a high pressure may be made to travel at cross-current with the oil stream, and the oil caused to spray by the impact of the compressed air. Steam may also be used in the same manner, with the added advantage that it imparts a certain amount of hydrogen gas which unites with the oil. However, latter day practice is treading away from compressed air, and the prevailing custom shows that the average shop is using air at only six to 12 oz. pressure with oil at from 20 to 50 lbs., and with gas at from two to four oz.

One of the principal sources of grief which the heat treater has to contend with is the blower problem. The two prevailing methods are the central air installation which embraces the distribution of air through pipe lines, and the unit blower application, where a small fan is connected to each furnace. Both processes have their advantages, but it has been conclusively proven that no fuel burning equipment has as low power factor as the small unit blower, which enables not only individual control, simplicity and quietness of operation, but which has frequently saved its first cost from the difference, as against the central system, in operating power during a reaonably short period. No matter how small any installation of a central system, where additional equipment is at all probable, the subsequent additions in furnaces usually exceed the original provision for air, whereas the unit system easily provides for this.

Just a word about furnaces and burner nozzles. There are more than a dozen large builders of reliable heat treating furnaces in the United States, and their products are, in the main, uniform. While many of these manufacturers have made progressive strides in furnace design and construction, still there appears to be in most furnaces—especially in the semi-muffle type—a conservative standardization. Whether this is due to lack of imaginative ingenuity, or simply a frank admission that the present type of furnace has reached its perfection, I do not pretend to advance. From time to time a builder will improve a door lifting device, or add sturdier legs, or heavier refractory linings, but I will venture to predict that the coming year will see some radical departures in furnace construction.

Already I notice a tendency to decrease the number of burner nozzles on heat treating furnaces. It has ever been the theory of the furnace builder that inasmuch as heat must be applied with uniformity and not in spots only; numerous burner tips must be located along the side of the furnace. May I not draw a comparison that the days of the bucket brigade are over, and that with two healthy streams of water a modern fire department can do more than with 1,000 water buckets? Any furnace fired with 20 nozzles can be heated just as efficiently with two, or at most, with four, when properly spaced and of adequate capacity. It is like comparing 20 little water falls to the concentrated power of Niagara.

Let me also advise against the use of the "pepper-box" or "honeycomb" type of nozzle now in general use. These nozzles can easily withstand high temperatures in a large combustion box, but are apt to fuse and oxidize in a small furnace. They should never be used in a high speed furnace. Also I find that in most furnaces the nozzle tips are set well back in the channel-port of the refractory lining, and if the nozzle tip is of the pepper-box variety, the restricted channel only shortens its usefulness. My experience has convinced me that a nozzle should be of a single orifice, set flush with the inside wall of the furnace lining and cemented in so that no metal is exposed to the heat.

A thing of paramount importance in heat treating is the furnace atmosphere, which is influenced directly by the proportions of fuel and air, as well as the intimacy of their mixture. The result of incorrect proportions of fuel and air and imperfect mixture thereof is often the cause of injury to the steel, and will even cause carbonizing boxes to scale ex-

*From Journal of Steel Treaters' Society.

cessively and become prematurely useless.

Furnace atmosphere also has its bearing on the heating of high-speed steel. In shops where the high-speed furnaces are kept constantly at a working temperature, there is little chance of damaging the most delicate high speed steel. But in the hardening room, where a high-speed furnace is used intermittently there is danger because the operator will employ a highly oxidizing blast to bring a cold furnace up to heat quickly, and then neglect to change the character of the flame when entering the steel.

This calls to mind an incident which happened recently, which might well be called the "Parable of the Small Gas Meter." A steel treater had a carbonizing oven and cyanide furnace, the combined gas consumption of both taxing the capacity of the single gas meter, but he was not aware of it. He later installed a high speed furnace, and in making the burner installation of this appliance I suggested that he had better notify the gas company to install a larger meter. Evidently he thought a larger meter would register more gas in proportion than the present meter, thus increasing his unit fuel consumption on his present basis of production. At any rate, the small meter remained, and when all three furnaces were in operation he could not keep from "pitting" the high speed steel because of insufficient gas and excess air. The moral of this is that if you use gas in your heat treating room, always consult the gas company in making changes or additions to your equipment. They are genuinely anxious to sell you service—not merely fuel.

Another thing, never use a furnace that is too big for the work required. It is poor economy. I know of a shop in Chicago where they bought a big semi-muffle furnace, which plays as many roles as the bass-drummer in an "Uncle Tom's Cabin" troupe. They use it for forging, annealing and case hardening, and I might also add that in the latter practice this same firm also seal their carbonized boxes with Portland cement instead of fire-clay.

There are constantly little occurrences in the hardening room which are perplexing, especially to the inexperienced steel treater. I have often heard a heat treater assail the gas company for poor gas service, when all in the world the matter was that the salt mixture in his potassium chloride (clean heat) bath was ready for the embalmer, or else perhaps he was quenching his steel in oil or water which was far too hot. On the other hand, I have seen the heat treater blamed when gears which he had hardened and sent on into another department had subsequently been ground with the wrong sort of abrasive wheel.

The Question is "Will It Work?

A Claim That the Introduction of Chemical and Metallurgical Science Has Not Proved to Be a Panacea for All Industrial Evils.

By HENRY TRAPHAGEN

THE introduction of chemical and metallurgical science in our industries has not proved to be the panacea for all industrial evils that the layman imagined it to be. Profound scientific learning or skill in chemical technique will not always solve our industrial problems. After all is said and done, it appears to me that the one big outstanding dominant question in the industries must be, "Will it work?"

Is the material suitable for the purpose for which it is sold. Is the material capable of weathering abuse in unskilled hands? Is the material sound; is it uniform; is it the finished product of skilful craftsmanship or a flimsy makeshift designed to meet an arbitrary formula? These are some of the questions that the conscientious manufacturer must ask himself if he would know the real worth of his product.

The consumer is little concerned with how a product is made; it is of little moment to him what the manufacturer puts into the material. But he is vastly interested in how much service he can get out of it. Again, it is the same old question: "Will it work?"

It requires more than a knowledge of metallurgy to run a steel mill. The most expert chemist on earth cannot make a good drill if he is not a mechanic, nor can he devise tests that will show up the practical defects in such a drill if he is not acquainted with the mechanical details of such tools. The most carefully computed mixture that ever graced a charge slip will not make a good heat if the cupola tender does not know how to patch his lining or if the chemist does not know how to recognize physically defective coke. All the chemical analyses in Christendom will not make a porous casting sound. The best ingot that was ever poured will not produce a trustworthy rail if the roller tears and pinches the billet in rolling, and so it goes. No product is any better than its weakest point. There is that ever present chain of operations, each link separate, yet indissolubly joined with the other. If one link is faulty the chain is useless. Truly no product is any better than the man who makes it. And this is doubly true in the various metal industries.

Science is Wonderful

Metallurgical science is a wonderful thing. Wizards of the past and present are the creditors of the world, for the debt can never be fully paid. Still it must be remembered that metallurgy and chemistry are not cure-alls. The scientist cannot make a workman out of an idiot; nor can he evolve that mystic formula that can wipe out and supersede craftsmanship.

Things of metal have always been and always will be products of personal skill and experience. It would be well for us to pause, think, and think deeply and earnestly, before we embrace any mechanical contraption that purports to be a substitute for human intelligence. The light of science has shown the way through dark and devious paths. The flaming torch of the pioneer has given way to the searchlight of organized science. Yet that all-powerful light is in imminent danger amid the disconcerted flashes of a million lesser ill-directed lights.

Weeds grow thicker and faster than flowers. The broad-minded, practical, experienced scientist is one thing. The arbitrary, shallow, inexperienced chief chemist or metallurgist, found in many plants, is quite another. How often do we see perfectly good steel rejected because the phosphorus content may be one thousandth of one per cent. above an arbitrary limit. And on the other hand, how often do we witness the curious procedure of accepting a carload of defective castings on the evidence of a doctored and carefully nursed test-bar.

Producer Must Analyze

The chemist and metallurgist in the plant of a large producer functions in quite a different manner than the fellow in the shop of a consumer. The producer must analyze in order that the product may be sorted. He must attempt to cater to the wants of many and varied customers. Hence, the number of laboratories that are to be found in our large producing mills. Keep in mind that a chemical analysis is a sorting process and nothing else. It is no guarantee of workmanship, it is no protection against physical defects, and the fact that metal may be of proper composition will not prevent a sloppy, ignorant workman from ruining good material.

The gentleman who buys must have a laboratory. He must imitate the big fellow. He must analyze a package of drillings from every shipment; he must copy impossible specifications from handbooks and force them upon the producer. He must rave about accuracy in composition, and at the same time let the question of workmanship go to pot. He sees fit to allow a youngster fresh from college who cannot drive a nail with six hammers dictate to the producer, whose product is backed up by years of experience.

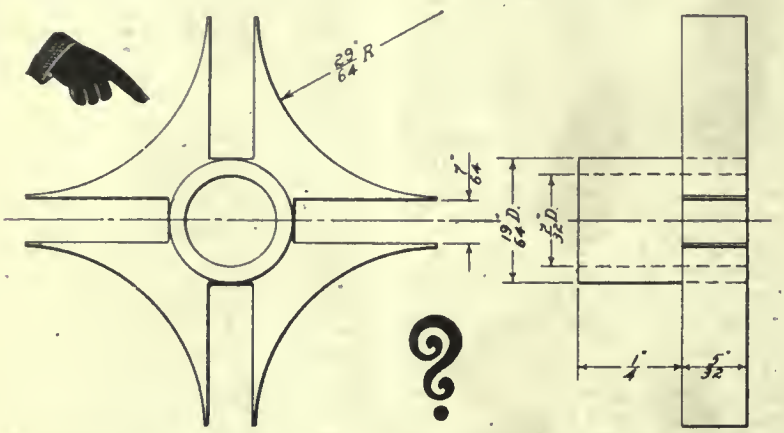
Now what has been the result of all this? Naturally, the customer must be pleased. The producers have carefully

Continued on page 69

WHAT OUR READERS THINK AND DO

HERE'S A PROBLEM

Small jobbing shops frequently are called upon to do work that taxes the ingenuity of the man in charge, and when small quantities of certain pieces



BE SURE AND SEND IN YOUR IDEAS ON THIS PROBLEM. WE WANT THEM.

are required to be produced, the time allowed does not permit of expensive jigs and fixtures by which the work could be carried out successfully. On the other hand the piece may be so intricate or necessitate such close accuracy that great care must be exercised in deciding on the process of manufacture so as to avoid loss through the possibility of errors arising from the method adopted.

Such a job is shown in the accompanying sketch. These pieces represent a Geneva movement that forms part of the mechanism for moving picture machines. Unless the different sections of this piece are absolutely uniform and to dimensions they are not suitable for the duty they are required to perform. A short time ago a small shop in Montreal secured a trial order for about one hundred of these, with the prospect of obtaining a considerably larger order if the work proved satisfactory. The trial quantity was completed, but quite a number of pieces failed to pass the customer's inspection. At present the superintendent of the shop is devising other methods of doing the work, and he is desirous of learning of ways and means from some of the readers of Canadian Machinery as to the best method of accomplishing the job.

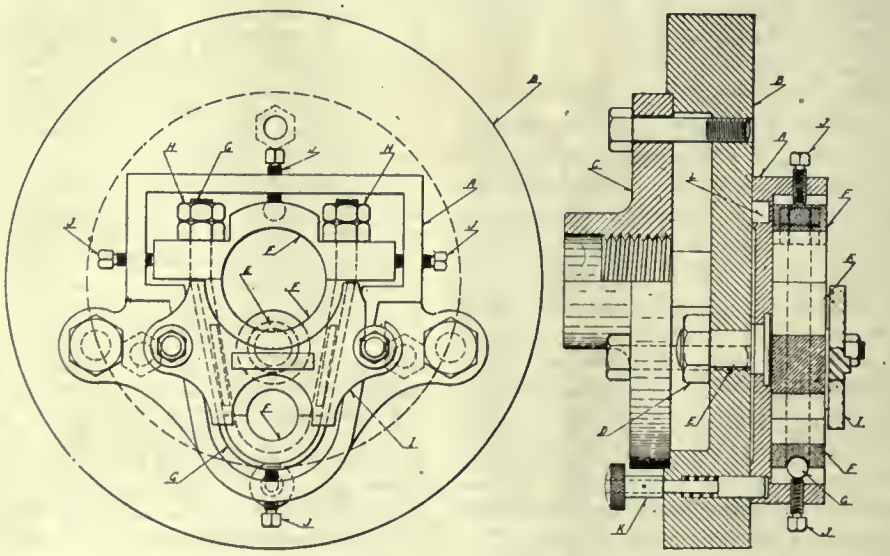
The piece is made of cold rolled steel and the dimensions and uniformity must be very accurate. Production would approximate 5,000 yearly.

Readers are requested to send in their ideas as to the best way of manufacturing this Geneva movement, and an estimate of the cost of production per 100. We shall, of course, pay for all acceptable material as usual.

BORING JIG FOR THREE-PIECE BRASSES

By J. H. Houldsworth

The accompanying drawing illustrates the assembly of a box jig used for boring out the two holes in the three-piece brasses for the cutter levers of the tiffin nail machines. This is a marked improvement over the old method of holding the brasses in a chuck, as it insures greater accuracy, both in centre distance and alignment of the holes. In the fixture shown the jig A is secured to the special face plate B by a bolt on either side, and midway in the centre line of these bolts is the swivel bolt E, held in position by the nut D. Ample space is provided for operating the nut by fitting the auxiliary face plate with four bearing lugs. The jig face plate is secured to the lathe face plate by three equally spaced bolts. The three brasses F. F. F have semi-circular grooves on the sides, and are firmly bolted together by means of the round strap bolt G and the nuts H, H. The swinging clamp 1 is provided with two small strips for clamping the brasses in the fixture. The four screws J are used to line up the brasses before boring. The swivel bolt E is located the same distance from the centre of the two holes, so that when one is bored the clamping bolts are removed and the stop pin K drawn back, to permit of turning the fixture through 180 degrees, when the stop pin engages with the small hole L, thus bringing the small hole in the correct position for boring. When these brasses are worked in quantities this jig is highly efficient and economical.



ASSEMBLED VIEW OF THE BORING JIG.

Want Locomotive.—The Department of Railways and Canals, Ottawa, is asking for tenders on a new or second hand switching locomotive: One (1) only 0-4-0 switching engine, 50 or 60 tons, saddle tank type preferred, but would accept engine with tender if former not obtainable. Quote price for delivery at Government siding, Merritton, Ont., freight, duty and all other charges paid.

MAKING EFFICIENT BEVELS

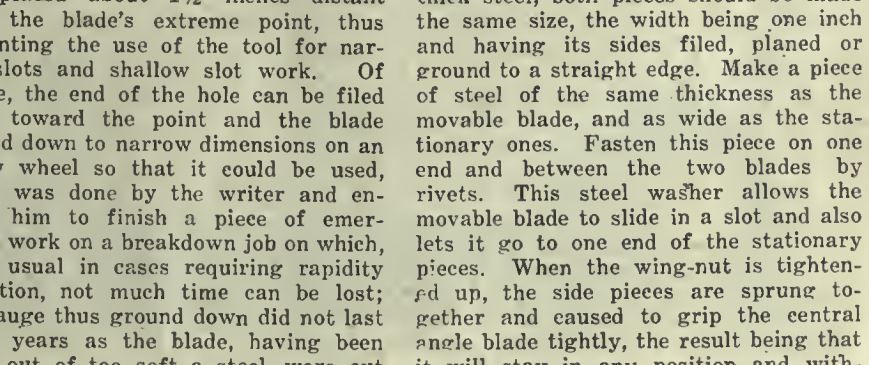
By W. S. Standiford

ONE of the most important tools in frequent use by machinists and other metal workers for testing the accuracy of angle work as it progresses is the bevel gauge. This instrument, as bought in the hardware stores, has two drawbacks which are as follows: The blade is made too wide so that when a machinist, etc., has to measure an angle on the edge of a narrow slot which he is turning in a lathe, the tool is altogether useless, as it cannot be used at all in such a case. Where a very shallow slot, having sufficient width to allow insertion of bevel gauge blade, is being turned, it will be found that the end of the opening slot in blade does not allow the tightening screw to approach the blade point, which is essential in order to measure angles on shallow depth work.

Most bevel gauges have the end of slot placed about 1½ inches distant from the blade's extreme point, thus preventing the use of the tool for narrow slots and shallow slot work. Of course, the end of the hole can be filed down toward the point and the blade ground down to narrow dimensions on an emery wheel so that it could be used, which was done by the writer and enabled him to finish a piece of emergency work on a breakdown job on which, as is usual in cases requiring rapidity of action, not much time can be lost; the gauge thus ground down did not last many years as the blade, having been made out of too soft a steel, wore out rapidly. Since then, the writer has made the gauge depicted in Fig. 1 out of high carbon steel, and it still shows no appreciable wear.

To make one like it proceed as follows: Get from a hardware store a small threaded square shouldered bolt of sufficient length to suit thicknesses of steel for blades, and ⅛ or 5-32-inch diameter. If a bolt with a square shoulder is unobtainable, it will either be necessary to make one or else rivet a piece of steel placed lengthwise on one piece so as to prevent the bolt from turning when the wing-nut is tightened up. Select a bolt with a wing-nut on it instead of one having a round thumb screw, as the former allows of greater tightening pressure.

If a bolt of ⅛ or 5-32-inch is not procurable, send away to any model maker's supply house. It is essential to use as thin a bolt as possible in order to make use of as narrow a blade as is practicable, which allows of working in small slots. Bevel gauges can be made any desired size, but the one illustrated is just the right length in ease of handling and for general all-round work. Make the slotted blade out of ⅛-inch thick steel, the slot to be made first and of sufficient width so as to let the fastening bolt slide easily along it. The blade should be made either ½ or ⅝ inch wide, these sizes making a tool that can be used in various chamfering work and other difficult places where the ordinary article would be entirely useless. Five inches long is a good length to make the movable blade and also the horizontal ones. The latter is to be constructed out of two pieces of ⅛-inch thick steel, both pieces should be made the same size, the width being one inch and having its sides filed, planed or ground to a straight edge. Make a piece of steel of the same thickness as the movable blade, and as wide as the stationary ones. Fasten this piece on one end and between the two blades by rivets. This steel washer allows the movable blade to slide in a slot and also lets it go to one end of the stationary pieces. When the wing-nut is tightened up, the side pieces are sprung together and caused to grip the central angle blade tightly, the result being that it will stay in any position and withstand a fair amount of hard knocks before it alters its setting. In use this type of device proves to be very handy as it can be adjusted for chamfering work on both deep and very narrow slots. The flat edge, or side, on the movable blade makes a very handy depth gauge, thus two tools are combined in one, either of which can be used separately when the other is not set.



FIGS. 1 AND 2—SHOWING TYPES OF GAUGES DESCRIBED IN TEXT.

Another novel and very effective form of bevel gauge is shown in Fig. 2. This tool is made out of high carbon tool steel plate annealed; ⅛-inch thickness is a good size. It is cut out in triangular shape, the shoulder on the fastening bolt sliding in the curved slots. When the writer first made this gauge the slots were curved in circular form as shown in the photograph of sketch, but if I ever make another one, the slots will be extended out to the extreme corners of the triangle, as I believe that it would be much better, although experience shows that the tool is very handy as it is. The beam, like the three-cornered piece, is made out of ⅛-inch high carbon steel plate, as this thickness makes a very compact and long wearing tool. No description of it is necessary, as the illustration shows the construction plainly, it only being essential that the edges of the square shouldered holding bolt should be rounded slightly with a file, so as to allow it to slide freely in the curved parts of slot. This gauge is shown with its beam set at an angle to the long side of the triangular section, but as will readily be seen, it can be used with any one of its angles, thus allowing of chamfering work in and around and close to metal shoulders on metal being turned in the lathe or for shaper or planer work. Metal shoulders being in the way generally interfere with the setting and working of the ordinary type of bevel gauge. The sharp point of the triangle will allow it to be set and used in chamfering the edges of a very narrow and shallow slot.

In conclusion, any mechanic who constructs either type of instrument, will find them to give good satisfaction on all classes of work, and if they are made out of high carbon steel, long wearing tools will be the result of the construction.

PURIFYING OIL BY CENTRIFUGAL ACTION

For many years there has been in use in most of the large engineering works of this country a centrifugal separating machine which removes the oil from iron and steel turnings or borings, and thus permits it to be used over again. The idea which underlies this machine has now been carried further and applied to the removal of dust and dirt which unavoidably collect in oil used in the lubricating systems of marine and other large engines. The new machine is very similar in form and operates on the same principle as the now well-known centrifugal cream separator. The foul oil is fed continuously into the machine through a strainer which catches any gross particles, precisely as milk is fed into the cream separator. The purified oil escapes continuously, while the dust and dirt collect on the inner surface of the separating drum. Provision is made by which the attendant can instantly tell when the machine is choked with the deposited impurities.

For many years an employee of the Steel & Radiation Co., Limited, Toronto, H. M. Alexander relinquishes his position with the company to become secretary-treasurer of the Toronto Refining & Manufacturing Co. and the Mona Oil Co.

DEVELOPMENTS IN SHOP EQUIPMENT

AUTOMATIC TURRET LATHE

THE illustration depicts a turret lathe recently put out by Alfred Herbert, Ltd., Coventry, England, with offices at 1-3 Jarvis Street, Toronto, Canada. This machine has a maximum swing over the bed of 18½ inches, and is known as the No. 5 model. All operations are automatic, except chucking, and the machine stops automatically at the finishing of a piece. There are a number of interesting features to the lathe, such as the longitudinal adjustment of the headstock, the independent operation of the front and rear cross-slides, and the low position of the spindle, which makes setting up an easier task.

Constant-speed drive by a 4 inch belt is employed, the 10 inch driving pulley running on ball bearings. The drive can be engaged for starting the machine by means of a friction clutch operated by a hand lever. The headstock is adjustable along the bed for a length of 6 inches and its mechanism is completely enclosed, the gears running in oil.

Spindle Speeds

There are five spindle speeds that are changed automatically. It is claimed that the changing is performed instantaneously and silently and that it can take place while the tools are cutting, if necessary. Change gears are provided to give six principal or substantive speeds, by which the range of the automatically-operated speeds is changed. Since these five automatically changed speeds can be used with each substantive speed, a total number of 30 steps is provided in a range from 14 to 411 r.p.m., the maximum gear ratio being 28.5 to 1. If desired, change gears can be furnished to give additional speeds.

The hollow spindle is 5⅛ inches in diameter at the front neck and has a flange on the nose 10 inches in diameter. It has a bore of 3⅝ inches, runs in white metal bearings and is provided with a ball thrust bearing. It can be stopped automatically at any instant and then restarted automatically in time for the next cut. This action is valuable, particularly to enable the withdrawing of a tool at the end of a cut without leaving a helical mark on the work.

The turret has four faces, machined square with the spindle. The tool holes are 2⅛ inchs in diameter. The turret is mounted on a slide having a working stroke of 13 inches. It is indexed at the extreme back position and then clamped automatically.

The cam controlling the action of the turret consists of a drum running in oil and driven directly by a worm. It is provided with two grooves, one for moving the turret slide and the other for indexing the turret. Since the latter action occurs only when the turret is in its extreme back position, all of the working stroke is available for actual machining operations. The turret-actuating groove is cut like a screw-thread and returns upon itself, so that the turret moves with a smooth and steady motion. It is claimed that no irregularity or jumping occurs, even when taking heavy cuts.

For each complete forward and return movement of the turret the cam makes three complete revolutions. Rotation of the turret to present a different tool to the work requires but 1.1 second, and the time for a complete cycle of the machine at high speed is only 48 seconds. The turret is 11¼ inches in diameter, and the centres of the tool holes are 4⅛ inches above the slide. The distance between the face of the turret and the face of the spindle varies from 15 inch as a minimum to 34 inches as a maximum.

Cross-Slides

The front and back cross-slides are independent of each other in their action, and can be set to work either at the same time or separately, as required. For example, roughing and finishing facing cuts can be taken simultaneously. The cross-slide cams can be adjusted to operate at any part of the cycle of operations. Each cross-slide is provided with a double toolholder and a stop with screw adjustment for regulating the diameter turned.

The centre of the spindle is 4½ inches above the top of the front slide and 3½ inches above the back slide. The slides have adjustments along the bed of 7½ inches independently of each other. The horizontal distance from the spindle to cross-slides can be varied from nothing to 11½ inches, power feed being available for a stroke of 4½ inches. The maximum diameter admitted between the cross-slides is 16 inches. Ample room is provided under the tools for the chips to get away, the chute for this purpose being plainly visible in the illustration.

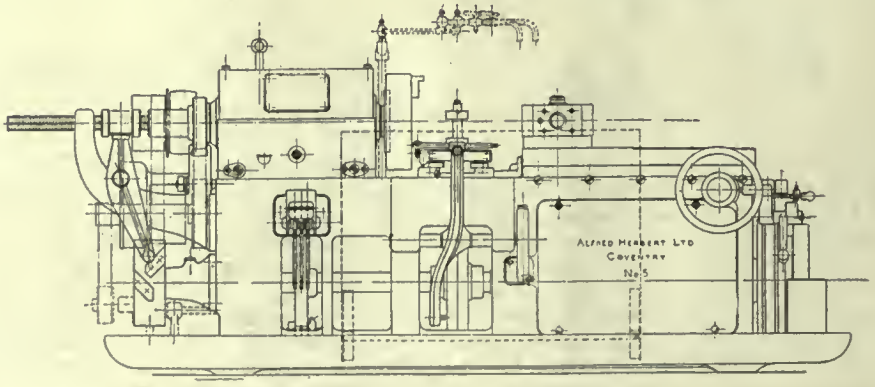
Ranges of Feed

The "self-selecting" feed motion provides for both the turret and the cross-slides, ranges of 7 feeds, any one of which can be brought into action instantly at any part of the cycle, even during a cut, if required. The feeds are driven from the headstocks, but the quick or idle motions are driven from the constant-speed driving pulley, so that the idle motion always takes place at the same rate of speed. It is claimed that the range of feeds is sufficiently broad so that it is never necessary to change the feed cams. The feed of the turret slide varies from 1 to 144 revolutions of the spindle per inch of feed, and that of the cross-slides from 40 to 366 revolutions per inch.

The bed is a box casting. It is built low, the spindle being only 40½ inches above the floor, so that the machine can be tooled up and attended more conveniently. The tray extends the full length of the bed and provides ample room for chips.

A pump with fittings, including splash guards, is supplied at extra cost. Oil supply through the turret can be furnished for use with hollow tools for carrying lubricant to the cutting edges.

A back-facing attachment can be furnished if desired. It is claimed that its



LINE DRAWING OF THE NO. 5 TURRET LATHE.

use often enables a piece to be completely machined at one setting instead of two.

The 15 inch Coventry chuck is suitable for use with this machine, although special chucking fixtures can be furnished for work that cannot be handled by it. A standard tool outfit can be supplied and the maker recommends its use for general work. The outfit includes a centering tool, facing tools for the cross-slides, boring bars and combination boring, turning, and facing tools that are provided with an overhead support.

The machine is intended to be driven by a 7 h.p. motor. The floor space required is 6 x 12 ft., the approximate net weight is 8,500 lbs., and the size when boxed for shipment is 340 cu. ft.

COMBINATION TOOLHOLDER

The toolholder as illustrated has been placed on the market by Maurice H. Derringer, 3133 N. Eighth Street, Philadelphia, Pa. It is intended for medium sized work on lathes from 12-in. to 20-in. swing. On the end shown at the left is a yoke which can be swung to either side of the bar. One side of the bar is adapted for holding square stock up to 5-16-in. and the other side, formed as a V-block, will hold round stock from ⅛ to 9-16 in. in diameter. This groove is useful for holding indicator stems as well as boring or internal-threading tools. When the holder is placed in position in a lathe, the screw in the lathe toolpost can be tightened on the end of the tool, thus holding it rigidly. The yoke may be easily removed by taking out the taper pin which holds it. The other end of the holder is provided with a goose neck which can be locked in position at any angle. This neck will hold 5-16-in. tool stock, being especially adapted to thread cutting.

GENERAL VIEW OF THE HOLDER.

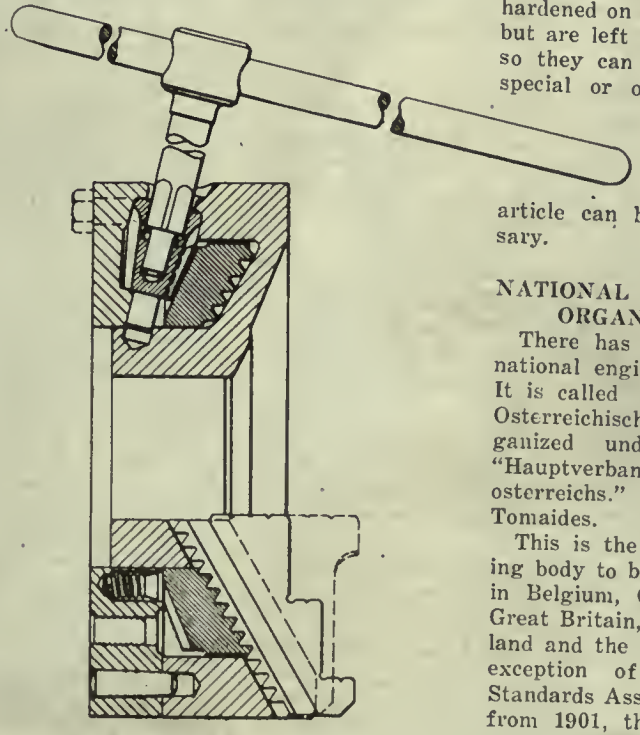
IMPROVED SPIRAL CHUCKS

The Charles Taylor, Limited, of Birmingham, England, have placed on the market their patent improved spiral chucks. These chucks are being handled in Canada by Messrs. Williams & Wilson, 84 Inspector St., Montreal, and they are exclusive agents for the same.

These chucks, of which we show illustrations and line drawings, embody many interesting and important features of design that add greatly to their efficiency and durability under continual and exacting service, and are the recent outcome of 35 years of manufacture and study of self centring chuck requirements.

The construction of the chuck is such that the movement of the jaws is not at right angles to the lathe spindle, but inclines inwards at an angle of about 30 degrees. This design permits of a thrust upon the spiral rack and more directly back of the jaws, thus minimizing the tendency to tilt that is said to be always present in chuck jaws where the movement of the jaws is square with chuck axis. The V shape of the rack permits of a finer pitch, giving greater gripping power and the inclined position provides for a better distribution of the pressure, as the bulk of this is transmitted through the solid metal of the jaws and square with the axial line of the rack.

The pinion for operating the spiral rack is non-projecting and the bearing



LINE DRAWING OF CHUCK.

PHOTOGRAPHS OF CHUCK.

surfaces of all moving parts are hardened and ground. This adds very greatly to the life of the chuck. Special provision is made for taking up any slight wear of the moving parts. Every part of these chucks is made to limit gauges and is interchangeable and every chuck is guaranteed to grip true to within .002 measured 3 inches from face of jaws. They are claimed to be the tightest gripping self-centring chucks made.

The strength of the parts of this improved chuck permits of a length of key handle approximately twice that of ordinary chucks, giving corresponding greater grip and providing this extra grip by leverage that loses nothing in extra friction. In addition to the usual 3-step and bar jaws, "soft" blank jaws are supplied. These blank jaws are hardened on the teeth to withstand wear, but are left soft on front face and grip, so they can be machined to hold any special or odd shaped article. They are of high class case-hardening steel and after machining to hold the special article can be case-hardened, if necessary.

NATIONAL STANDARDIZING BODY ORGANIZED IN AUSTRIA

There has been formed in Austria a national engineering standardizing body. It is called the "Normenausschuss der Osterreichischen Industrie" and is organized under the auspices of the "Hauptverband der Industrie Deutsch-osterreichs." The secretary is Dr. Jaro Tomaides.

This is the tenth national standardizing body to be formed, the others being in Belgium, Canada, France, Germany, Great Britain, Holland, Sweden, Switzerland and the United States. With the exception of the British Engineering Standards Association, whose work dates from 1901, they have all been formed since beginning of the European war.

Keep Buyers in the Market

PRICE deflation is a matter that many papers do not care to say much about, as it is a question that can cause a great deal of misunderstanding. There are always those willing and ready to read into an article things and ideas that were never intended.

But the question of prices is so tied up with every phase of business that it must be considered. Men are talking about the process, and it is more marked now than it has been for many months. It was expected when the armistice was signed that there would be a rapid drop in prices. In fact many people were looking for a crack right then and there, but it was postponed, and from the way things are shaping now it would appear that the postponement had been all for the best.

The danger in this situation lies in the fact that we may have a rapidly falling market, a thing that is dangerous and undesirable. Were this to come to pass we would find buyers leaving the market entirely, or if they remained it would be only to supply their immediate and urgent wants, and there is nothing more miserable than that sort of trading.

Canadian Machinery has discussed this matter with many men in the iron, steel and machine tool field during the past weeks, and when one finds Judge Gary making it the centre of his annual address to the Iron and Steel Institute there is little room to doubt that it is the real question of the hour.

The desirable solution is to keep the buyers in the market. By this we are not urging any buyer to go in hard now. His own common sense, and his knowledge of his own field, must, in the last analysis, determine the size or value of his purchases.

The business world, in many cases, was quick to respond to the touch of higher costs with higher selling prices. Some of them undoubtedly went the limit in this and worked on the principle of piling on all the traffic would bear.

When the tide is running in the opposite direction these same interests, if they are to serve their field well, should be just as keen to make adjustments in the other direction.

If there is a determined all-round resistance to price declines, if there are no mutual concessions, no tempering of contracts to meet changed conditions in any line, then we are facing a serious situation.

What will result? The buyer will be forced to keep out because he will be afraid of being ruined if he buys at high prices, with the prospect ahead of him of selling at a lower level.

If, on the other hand, there is a spirit of reasonable business action, of concession wherever possible, of a desire to consider the proposition and the problem of the other man, then it may be possible to get the country cleared out of the high-cost materials in all lines, much of which is still held in various centres. If the whole loss were shouldered on any one section it would mean ruin in many cases.

The manager of one of our large establishments puts the case well as follows: "Let us be reasonable, and not afraid; we are going through the period of deflation that we thought was coming two years ago, and until we get through it we will never be down to a solid basis where we can go ahead and do constructive work again. Let us guard against doing anything that will bring us face to face with unemployment. Let us keep the buyers in the market even if we make very little money—this is not a season of large profits, and we must realize it. This situation will work out well if we keep our heads, use common sense and attend to business. I am not afraid of it."

Nothing But Wages

IT seems difficult to realize at times the length to which workers have gone in making demands, each of which was like a millstone tied to the neck of industry. In Italy, for instance, when the shops refused a 50 per cent. wage advance because there had previously been a 200 per cent. increase, unions determined on the following programme in order to coerce the employers, which is given in the words of the manifesto issued by the labor leaders:—

1. Production must be reduced to a minimum.
2. Work must be simulated, thus obviating any absurd pretext on the part of the management to resort to dismissal or lockout.
3. No files or other tool should be used unless they be in perfect order and fully suitable to the job on hand.
4. Every repair to machinery must take the longest possible time.
5. Nobody, for any reason, should attend to a different job from the one on hand, as repairs, oiling, etc.

Finally it was stated that if employers dismissed the workmen they should take no notice of the dismissal, but continue to enter the plant. Should the management resort to forcible ejection the men were instructed by their union leaders to proceed to violence. Should a lockout be enforced it was declared that the works should be re-entered at all costs, even by breaking in.

No doubt you will say that was an extreme case. Quite so, but these extreme cases are simply the logical outcome of any system that looks upon successful negotiation of wages and working conditions as securing a jug-handled document, with the handle in their own grasp.

Employers to-day are willing in many cases to meet their men on grounds quite different to those of some years past—if they only get the chance to do it.

There is a new school of employers, and they are, for the most part, vastly different to the old autocratic type.

It is a serious thing for a man himself when the matter of hours and wages get so impressed upon his mind that he speaks, thinks and acts only in this narrowed sphere.

The employer who will not recognize initiative, effort, and industry may exist now, but if he does he represents a fast-dwindling minority.

The sense of accomplishment is greater than the recompense of wages, and the realization of work well done cannot be measured in terms of dollars and cents.

Judge Gary Sanely Optimistic About Future

(By a Staff Representative)

NEW YORK.—The address of Judge Gary to the members of the Iron and Steel Institute is looked forward to each year as a statement that will give the estimate the steel world of United States has of business conditions, and prospects of their betterment or otherwise.

Judge Gary spoke plainly on this matter. There was no effort to mince matters. When the speaker was through reading his address there was a feeling that he had indulged to too great an extent in a description of affairs in Europe, but when, in the lobbies afterward, steel men started to analyze the statement, they found that he had put his finger on the real situation, viz., that it was possible to resist price deflation to the point of keeping buyers out of the market, or, on the other hand, make the concessions necessary to keep the buyers in the market.

Just What Judge Gary Said

Speaking of the matter of prices, Judge Gary said:—

"In certain lines of the iron and steel industry there have of late been some decreases in the volume of new business and also voluntary reductions in selling prices. I consider this decidedly healthful. All, or nearly all, of us have for months been unable to supply the demands of our customers as to quantities or deliveries and our prices, considered as a whole, have resulted in profits. As a matter of course some adjustments will need to be made. The average of the general scale ought to be reduced equitably and relatively. Without referring to individual cases or lines of general business, I believe in many instances prices have been outrageously high. This observation applies more especially to middlemen, so called, and to smaller departments of industry. It also includes employes in certain trades; but it does not pertain under present conditions to the masses of workmen.

"The present tendency is toward a lower, more reasonable and fairer relative basis. The whole community desires and strives for this. The difficulty is found in the fact that every individual is perfectly willing that all others shall make reductions—the larger the better. As there was more or less a scramble for higher and still higher prices when they were advancing, there will be just as much selfishness in the enforced use of brakes when there is a tendency toward decreasing prices. Now, a general public, including particularly those who are neither sellers nor buyers to a large extent, will in one way or another bring about a fair and reasonable readjustment of prices. The law of supply and demand will be the principal factor.

"What shall be our attitude in these circumstances? I answer:—We must evidence the same disposition which was displayed before the Industrial Board in March, 1919, when our steel committee co-operated with the Government's representatives in the endeavor to secure a general, equitable, orderly and methodical reduction in the prices of all commodities and services. Let us be reasonable and just, reducing our prices if and when other reductions and costs permit, and then with level heads, clear minds and honest convictions, stand solid as against panic or lack of confidence in the industrial situation. Let us strive to be right. If we are right we can be determined and courageous. Let us as individuals consider the interest of all others. Our business is basic. It is perhaps one of the most important. We may, we must, exert an influence for stability throughout the business world at a time when readjustments are, more than usually, liable to provoke disturbed conditions."

Agreed That He Was Right

The iron and steel industry of United States attend the Institute meeting. The corporation heads and the independents are always there. It is the big chance the technical and operating heads have to meet the big executives, and also it is the big chance the former have of making the latter sit still and listen. When Judge Gary finishes, the meeting goes on with the discussion of highly technical matters. The steel barons may understand some of the discussion, but the chances are that much of it goes over their heads. But they do not bolt. They occupy the front seats and take their medicine in spite of the fact that practically all the steel men of the country are waiting around to meet them—for, as a matter of fact, there is a general scatteration of the members as soon as Judge Gary is through with his address.

One hears many exchanges of market news—for instance, that a fairly large tonnage of pig iron has sold at $40—that premium mills are doing in some cases as low as six cents on black sheets for Canada, with fair delivery, against 5.35 of the corporation, with no promise of quick action in the matter of shipment.

The rumors that the corporation might advance prices to cover the $50,000,000 which has been added to its freight bills, did not materialize in fact. If there had been any intention of making such a move, or had there been any necessity for it, three months ago was the time when it could have been put across. It would have a hard time trying to gain popularity now—in fact it could not be reconciled with the trend of Judge Gary's remarks, which were all pointed and tuned toward lower levels as soon as possible.

Of blue ruin talk there was none at all, in fact, the head of the Steel Corporation is noted for pruning very severely anything that might be twisted or misconstrued to read like bread-line literature. All through the meeting there was a marked tendency to be frank and honest in discussing affairs and tendencies, and the impression was created that sane optimism and a wholesome confidence in the future could handle successfully the deflation tendencies which are now upon us.

Among important steel makers present besides Judge Gary were Charles M. Schwab, chairman of the Bethlehem Steel Corporation, and Eugene G. Grace, president of the Bethlehem Corporation; John A. Topping, chairman of the Republic Iron and Steel Company; James A. Campbell, president of the Youngstown Sheet and Tube Company; E. A. S. Clark, president of the Consolidated Steel Corporation; Willis L. King, vice-president of the Jones & Laughlin Company; R. P. Lamont, president of the American Steel Foundries Company; Clarence Howard, president of the Commonwealth Steel Company, and W. H. Brevoort, president of the Republic Steel Company.

The Descent.
—Lecocq in the Portland (Ore.) "Telegram."

MARKET DEVELOPMENTS

Volume of Business is Not Very Large Now

Pittsburgh Reports That Buyers Are Not Anxious to Take on Large Tonnages Yet—Machine Tool Market Finds Many Buyers Waiting to See What is Likely to Happen.

THE market is discussing prices more this week than for some time past. The annual address of Judge Gary at the meeting of the Iron and Steel Institute has no doubt helped to direct thought in that channel. The feeling is expressed in many places that the real question of the hour is keeping prices attractive enough to hold the buyers in the market. The opinion is freely expressed that by a resistance of the tendency toward lower levels the buyers may be forced out of the market.

Pittsburgh reports that adjustments are being made in some existing contracts, although they are booked on the non-cancellation basis. Business there is fairly dull, and some of the mills are turning out more tonnage than is being placed on their books. New York also reports that the machine tool market in that centre is quiet. There is a feeling expressed in several quarters that the first of the year will see a revival of buying in many lines.

Supplies of steel are coming to hand fairly well, but there are lines yet where a large unsatisfied business still waits for deliveries. Sheets are scarce and wanted. Tubes come in, but not sufficient, and the prices are firm. Compared with pre-war days, it may be stated that four-inch tube—which is a standard size—to-day sells for 65 cents per foot, against 20c, which may be called a fair pre-war figure.

Machine tool houses are not doing a large business, but there is a scattered selling that is making figures fairly representative, when compared with previous months this year. The small tool trade has the same experience. A large number of small orders is the general report, no very large buying being done.

Scrap metal dealers are waiting for a turn in affairs, as their business is very much unsettled. Even were it to become established on a lower basis they might be able to go ahead, but it does not seem possible to reach that lower level with the knowledge that it will provide a real working basis.

THE IRON AND STEEL MARKETS REMAIN DULL AND LIFELESS

Special to CANADIAN MACHINERY.

PITTSBURGH, Oct. 28.—Few parallels can be found in history for the present dullness of the iron and steel markets. There is no new buying of any consequence in pig iron, none at all in semi-finished steel and scarcely any in finished steel. Pig iron and semi-finished steel contracts are, by trade custom, firm and not subject to cancellation, but there is latitude, particularly in pig iron, as to delivery. Sometimes, as a few months ago, the furnaces are behind in deliveries. Now many consumers are instructing furnaces to defer shipment or reduce the rate of shipment. In finished steel products, while there was a considerable volume of cancelling a few weeks ago there is further cancelling even now, together with many requests for postponement of shipment. If a correct statement could be prepared it would probably show that the independents as a whole are losing more by cancellations and postponements than they are gaining by booking new business, while, of course their order books are thinning each day by the amount that they ship.

Sometimes when orders fall off the iron and steel producers get into a pessimistic frame of mind and look on the dark side of things. That is not the case at this juncture. Those who held their prices down and those who sought the highest price obtainable, during the scarcity, realized very well that the situation could not last and that a stable basis with reasonable profits would have to be established some time, fair prices resulting in a healthy and full demand eventually. That is the prospect the producers are now looking forward to. There will have to be lower prices and there will have to be a period of light operation, but prices are not expected to become really unprofitable and the period of light operation is not expected to last long.

Producers Variously Situated

The steel market is a very disorderly one, and it is uncertain in what manner prices will decline and how long the decline will require. This complexity results from the producers being situated so variously. In times past, when demand stopped, the mills, or at least the large mills, would find themselves all in about the same position as to the volume of business on books. Then it was a clear case of holding prices until as much tonnage as possible had been squeezed out of the contracts. Eventually a point would be reached when there was more business to be obtained by reducing prices than by holding prices and shipping on contract.

Now, however, the mills are very variously situated. The Steel Corporation is booked for an average of about nine months. Some of the large independents are booked for three or four months, provided the market stays up moderately well. Other large independents have much less business on books. Among the small mills a few have a good volume of business but some have practically nothing. The state of order books today depends upon the price policy pursued this year. The mills that sought the highest prices had to keep their order books clear so as to be able to make early deliveries, for it was early deliveries that brought the highest prices, and at the same time they were quite unable to sell ahead. These mills have made a great deal of money and can well afford to sell at very low prices, even below cost, for the purpose of buying their way into the trade again. Some,

however, seem to prefer idleness. Instances are cropping out of a mill that was formerly one of the very highest priced sellers being now the lowest priced seller among the independents.

Steel Bars Cut

The Pittsburgh Crucible Steel Company suddenly began offering merchant steel bars in rounds, squares and flats, at 2.35c, which is the Steel Corporation price. Other independents have been quoting 3c to 3.25c, and while they learned within a day or two of the cut, they assert they will not meet the cut or even reduce prices, preferring to sit back and let the company involved fill up. In the past few weeks bars have been considered one of the strongest, if not the strongest, item in the whole list of steel products.

In plates the majority of the mills are naming 3.25c as "the market" and then cutting this figure, on individual inquiries, down to 3c as the limit. There are exceptions, however. Two western mills have quoted 2.65c and 2.75c respectively, and a sales representative of one of the mills is reported to have canvassed his trade offering to go $1 a ton below any quotation received elsewhere.

While it is still uncertain whether steel prices will experience most of their decline in the next few weeks or will hold, for, say, two or three months and then begin their real decline, predictions are already beginning to appear as to how long the general readjustment will require, the prediction being that next April will see the turning point, with prices at their minimum and with buying increasing.

There is much discussion as to the attitude of the United States Steel Corporation, which has maintained up to date the Industrial Board prices of March 21, 1919, except for two or three little advances made last August. There have been continued rumors for two months past that the corporation would advance its prices slightly, by an average of $3 or $4 a ton, based on the increasing costs caused by the freight rate advances of August 26. This would give the independents some encouragement to drop to the corporation price level. There is, however, the factor that since the war-time control there has been no realignment of prices, one price with another, on the basis of production cost and relative demand, and a horizontal advance in the Steel Corporation prices would hardly produce a fair and equitable price structure. Very few predict, however, that the independents will reduce their prices just to the Steel Corporation level, whatever that may be, the view being that when the independents get down to the corporation level they will have to cut under the corporation prices in order to get business.

Pig Iron and Coke

Two or three small lots of basic pig iron have been sold by furnace interests at $40, valley, marking a further decline in the market of $2 a ton, a total of $8.50 from the top price, reached late in August. In Bessemer iron there is recorded a decline of $1.50, to $47, valley, as a furnace interest has formally offered iron at that figure, though, as a matter of fact, a single carload represents the only sale actually reported. Foundry iron remains quotable at $47, valley. An inquiry for a round tonnage would no doubt develop a lower price, but the inquiry must first appear.

Pig iron cannot find its true level as long as coke is at an altogether fictitious level. There has been a spectacular decline in coke in the past week, but there is still much distance to travel. In approximately a week Connellsville furnace coke for spot shipment has dropped from $17 to $14. Foundry coke lags in the decline, being quotable at about $17, but in time it will respond to the furnace coke market. A price of $8.50, or half the recent $17 price, may be seen within a fortnight or a month, but as even that would be nearly six times the $1.50 price that prevailed in May, 1915, no one can say where the coke market will stop.

POINTS IN WEEK'S MARKETING NOTES

The independent steel mills are probably losing more by cancellations and postponements than they are booking in new business.

One Pittsburgh company has cut the price of merchant steel bars in rounds, squares, and flats to 2.35.

Quite a tonnage of basic pig iron has been disposed of at $40, which is quite a reduction from the high figure that was being exacted in August.

Machine tool business is fair in this district, but buying is scattered and not in large lots.

Boiler tubes are arriving, but there is still a large unfilled demand. They are still selling at 65c for a 4 in. tube against a price of 20 cents prior to the war.

New York machine tool market continues very dull, with few large buyers in sight.

A number of U. S. machine tool makers have been approached with a view to lowering their prices, but they are standing firm against such a move.

KEEP BUYERS IN THE MARKETS NOW

That Should be the Aim of the Dealers in all Lines as Far as Possible

TORONTO.—The machine tool, steel and iron trade has seen much better days than it is experiencing in this district just now, but the dealers are not inclined to complain. Some of them thumb over their records and find that June was just as bad as October is likely to turn out to be.

As has been the case for some time, there are no large buyers in the market. Rumors of fairly large lists having been put out are heard, but buying has not started with the movement that is likely to come a little later on.

Prices are still holding firm in nearly all lines of tools, although dealers are not saying much about this matter. Makers have given little indication of any intention on their part of cutting their selling prices.

Firms that sell to farmers report a good business. There is an increasing volume of trade in this way, as farmers are more and more equipping their premises with lighting sets and other forms of modern equipment.

Clearing the Stock

Steel merchants are having a good business, but there is not the pressure on them there was a month or so ago.

Many local dealers are not buying from the independents now. Neither are they getting deliveries from the corporation. Bookings placed with the latter a year ago in some cases are still unfilled. "We are going to get better figures from the premium mills now than before," stated one dealer, "and I would not be surprised to see them doing better than six cents, although I do not know of an actual case where less than 6.50 has been paid. When one considers that the Corporation price to Canada is 5.35, with no quick delivery, it is much better for us to get a tonnage from the mills at 6.50 with delivery. We don't mind paying 6.50 for black sheets now, as costs are still high, but when we had to put up as high as 8c a pound to bring sheets over here, it was too much and too dangerous to last long."

Making Concessions

The head of one of the merchandising firms in the steel trade stated to Machinery this morning: "There must be now a gradual bringing down of prices in all lines, and in order that this may be done there will have to be concessions made, and we are following this policy now. I believe it should be generally done, not in the way of price slashing, but in order that the price list may be kept interesting enough so that the buyers will not go out of the market and stay out. If we can work along this way for a time, we will arrive at a basis where business can go on without any

trouble. In this way it will be possible to avoid a period of unemployment, and it is very desirable for the present that we have as little unemployment as possible."

Have Lists Out Now

Quite a number of the manufacturers have lists out now of material on hand of which they wish to dispose. "It all goes to show," stated one dealer this morning as he looked over several of the lists, "that it is easy to get people to buy when the markets are high and rising, and when it is difficult to secure material. Many firms have gone ahead and bought wherever they could because they were afraid of having no supplies at all to fall back on. Now they are not so busy and stock is piling up on them." Dealers as a general thing are not much interested in the lists that are being sent out by the manufacturers, as in many cases they, the dealers, have all the material in stock and on the way that they can take care of in the present market."

Tubes are arriving in fair quantities now, but they show no sign of coming down in price. A fair comparison in price shows that in 1914 a four-inch tube was selling at about 20c per foot, while now the quotation is 65 cents. There is, the mills claim, difficulty in securing skelp for the making of tubes, and the feeling is that this will be one of the last lines to come down.

The demand for reinforcing is not very keen now, as the season is pretty well over.

One dealer made it plain to-day that he thought buyers would make a mistake if they stayed out of the market now in the hope of buying much cheaper later on. He did not counsel placing a heavy order now, as he was of the opinion that price changes might be made, but his point was that if buying ceases it will react all the way through and bring about unemployment, whereas, if all the different factors in trade adopt a reasonable attitude it will be possible to gradually get the high cost material out of the trade entirely without an overwhelming loss having to be borne by any particular person or firm.

Some of the offices seem to be getting a very fair share of business in small tools, although in no case is anything heard of large lists having been sent out. There is a rumor in the market that there may be some readjustment of prices, having special reference to high speed drills. There is nothing official in regard to the matter, but it comes from a very reliable source.

The scrap market has no interesting spots. The trade was in hopes that the recent adjustment of prices, which brought prices down, would react on scrap and cause dealing to get under way again at a lower level. This has not happened at a lower, higher, or the same level and business drags.

BRITISH TOOL MAKERS IN NO RUSH TO BRING DOWN THEIR PRICES

THAT British machine tool makers are in no hurry to lower prices, but that competition in weeks to come would decide their course to some extent, is the impression one gains from discussing the matter with Mr. P. V. Vernon, a director of the firm of Alfred Herbert, of Coventry, England.

"The condition of labor is not the most settled thing with us," remarked Mr. Vernon. "In fact we often are in the position of wondering what is coming next. Not many months ago there was a ruinous strike of the moulders, and just now the miners have quit work. Then machinists were out, and other engineering trades are talking strike. It all makes manufacturing conditions rather unsettled. With material we are not having much trouble obtaining it all at home, but the price we are paying is still high."

The system of taxation that is in vogue seems to have the tendency of keeping prices up. Manufacturers are allowed to make the same profit as they did in the two years previous to the war. Anything over and above that comes under the heading of excess profit, and of that the Government takes 60 per cent. and leaves the manufacturer with 40 per cent.

The competition in the machine tool business of the Old Country makers is pretty well divided between their contemporary firms at home and the U.S. builders. "Business has changed since the signing of the armistice," stated Mr. Vernon. "When the war was on our product was almost 100 per cent. for home consumption, it being all used in the turning out of munitions. Shortly after there came a change until we found that our business was one-eighth foreign and the rest home. When I left the figures showed that one-third of the business was foreign and the rest for home use. There has been a falling off in many lines, but it is common all over the world. I have been for some weeks in the machine tool and manufacturing centres of United States and I know that many of the big shops there are not booked very far ahead with business, neither are the big shops, such as the auto works, buying anything in the way of equipment just now."

British firms are not paying much attention to German trade yet. The German mark is so low in value that the Germans themselves cannot afford to buy from British firms, and the impression is gathered that as a rule the British firms are not particular about opening up trading with the German people.

Mr. Vernon is a firm believer in British houses wishing to open up for business in Canada making a personal study of the field here. "The ways of doing business are quite different in various countries," is his contention, "and once a person has been in Canada he understands far better the problem of the office or the representative here. Our British firms have been advised many times to do this very thing, to make a visit to the field and meet the people and find out their ways of doing business, and I am more firmly convinced than ever that it is a splendid thing for a British manufacturer to do."

The British makers of machine tools of the better class are not at all afraid of not being able to meet the competition of the rest of the makers. For a time the Japanese were putting a cheap tool on the market. They took one of the Alfred Herbert machines and called it—or rather the imitation machine they made from it—the "Alf," and put it out to the trade. "That move did not hurt us at all," remarked Mr. Vernon, "in fact the imitation and the use of part

TOOL BUILDERS ASKED TO REDUCE

But So Far Their Attitude is Based on Relation to Cost Prices

Special to CANADIAN MACHINERY.

NEW YORK, Oct. 28.—Aside from inquiries from the Reading Steel Casting Co., Reading, Pa., for 25 or 30 tools for an addition to its plant, there is little activity in Eastern machine tool markets. Business certainly shows no signs as yet of revival, and sellers do not look for any change in the situation until after Presidential election, and some go so far as to predict that present conditions will continue until the first of the year or later.

There are some scattered orders for single tools, but a majority of sellers in this market are doing little or nothing in the aggregate, as compared with what might be considered a normal business.

Some of the automobile companies have been conducting a sort of organized campaign to induce manufacturers in all lines to bring down prices. Some machine tool manufacturers, thus approached, have signified that they have no present intention of reducing prices; that their selling prices are based on production costs, plus a reasonable profit, and that they do not intend to change prices until costs can be reduced. There are some evidences of labor costs coming down, through the willingness of men out of jobs to work for less than they have been getting in the past year or two. Material costs, however, are not lower, as most manufacturers of machine tools are still getting high priced pig iron, castings and steel on contracts made some time ago.

MAPLELEAF

MOTOR TRUCKS

—*The Hardy Truck*

The motor is built according to the rigid standards and specifications of the famous whippet tanks.

The mechanism is simple, rugged, easily accessible and perfectly protected from dirt and grit.

The drive is the famous worm drive—silent in operation, proof against breakage, easy to keep lubricated.

In every detail the Mapleleaf is made to give satisfactory service under Canadian conditions.

Parts are standardized and interchangeable on all trucks of each model.

1½ to 5 tons capacity.

of our name never injured our business. As soon as we were able to put out tools after the war the Japanese imitation did not provide any real competition."

This is Mr. Vernon's first visit to Canada. With Mrs. Vernon he has been spending some weeks in United States before coming to this country. Together with Mr. Blair, the Canadian representative of the Alfred Herbert Co., he is making a study of the Canadian field with the idea of further extending their business in this country.

WON'T TAKE GOODS— EXCHANGE BLAMED

South American Firms Take Action That May Cause Great Loss

Buenos Ayres.—At a meeting here of representatives of American commission houses it developed that the total value of American goods rejected at this port owing to the falling prices and high exchange on the American dollar approximates $12,000,000.

Other large consignments of American goods are now en route to Buenos Ayres, and leading American firms are fearing a crisis unless the Federal Reserve administration relieves them from operation of the re-discount rules.

Most of the rejections were noted with regard to textiles, foodstuffs, machinery and steel.

CONDITIONS O.K. IN SCOTIA FIELD

Agreement Has Been Reached in Regard to Taking Iron Ore From Mines

Montreal.—Roy M. Wolvin, president of the Dominion Steel Corporation, returned after a two weeks' trip to the company's properties in Nova Scotia and Wabana. The steel industry, he said, was in a satisfactory condition, and he had been able to arrive at an agreement with the Newfoundland Government whereby the export of iron ore would be carried out under conditions favorable to the corporation and along the lines desired by those who had conceived the British Empire Steel Corporation.

A Worthy Booklet.—The reasons why American manufacturers are establishing plants in Canada at the rate of one a week are summarized in a booklet just issued by the Union Bank of Canada, entitled "A Canadian Plant—Why?" In the face of the growing strength of the "Made-in-Canada" movement, and the extension of the British Preferential Tariff, Canada, the booklet claims, is the logical location for a plant with which to handle British and Canadian trade.

F. H. WHITTON DIES IN HAMILTON

General Manager of Steel Co. of Canada Failed to Rally from Operation

Hamilton. — F. H. Whitton, general manager of the Steel Company of Canada, died at St. Joseph's Hospital, Hamilton. Mr. Whitton failed to rally from a serious operation performed on October 21.

In the death of Mr. Whitton, Hamilton loses one of the leading figures in its commercial life. Deceased was born in Northamptonshire, England, 61 years ago, and spent his early youth in that country. He attended college at Cambridge, but when 18 years of age came to Canada and entered the employ of the Grand Trunk Railway at Montreal. He later removed to the United States, but returned to Canada to assume the management of the Ontario Tack Company, which position he held till 1907. When the Steel Company of Canada was formed Mr. Whitton was appointed assistant general manager and in 1916 became general manager.

F. H. WHITTON.

Mr. Whitton was prominent in social and religious life, as well as in the commercial world, being a devout Roman Catholic and a member of many clubs. He attended St. Joseph's Church. His wife and one son, Corbett F. Whitton, assistant secretary of the Steel Company of Canada, survive.

Building Addition.—A four-storey addition is being made to the plant of the Fisher Body Company, of Canada, Ltd., at Walkerville, Ontario, and will be completed about the end of the year. The new building is of heavy mill construction and will have 75,000 square feet of floor space. It will be used for painting and trimming closed automobile bodies. When it is in operation the capacity of the closed body department will be increased about 80 per cent. The estimated cost of the addition is $275,000.

INCORPORATIONS

Incorporation has been granted to the British Radio Corporation of America to make, buy, sell, lease, etc., electric appliances of every description, including wireless, telephone apparatus, etc. Head office at Montreal, and capital stock $10,000.

The Hamilton-Bothwell Oil Co. has been incorporated at Bothwell with a capital of $300,000, to operate and deal in gas and oil lands, etc.

Ira Sessenwein Ltd. has been incorporated to carry on the business of scrap dealers in metals, rubber, etc. Place of business to be at Montreal, and capital placed at $30,000.

Incorporation is granted to "All-British Signal Company," with a capital of £80,000, and head office in Toronto. The company is to make or sell submarine signalling made by John Gardner.

Incorporation is granted to the Overseas Export Co. of Canada, to import, export, etc., all kinds of merchandise, machinery, chemicals, etc. The head office is to be at Montreal, and the capital is $100,000.

Dunwin Motors has been incorporated to buy, sell, trade in and make motors, autos, etc. The place of business is at Montreal and the capital is placed at $100,000.

During the war the shortage of copper induced the Germans to experiment with all kinds of substitutes, and it was found that iron acted satisfactorily for spacing pieces in steam turbines, but not for vanes. Nickel-plated or enamelled steel also failed to answer for this purpose. More promising results are expected, according to "Technik und Wirtschaft," from nitrogenized iron, prepared by a process in which the heater vanes are exposed to a current of gaseous ammonia, the nitrogen of which combines with the iron, while the hydrogen reduces any superficial oxide.

Coming to Canada?—A London, Eng., despatch says: "A big increase in emigration to Canada may be one result of the strike of British coal miners. Reports received from Morriston, near Swansea, Wales, state that many of the steel workers there who have been made idle by the strike have decided to emigrate to Canada at an early date.

Kingston. — The largest locomotive ever turned out of the Canadian Locomotive Works left the plant to go into commission on the G. T. R. It is of special design for hauling heavy freight trains over difficult grades, and will be employed as a transfer engine between Toronto and York.

Planning and Producing with the Dumore

THE Reid Motor Co., of Hartford, Conn., has selected the Dumore Grinder because it has on so many occasions solved difficult problems for this Company. The work is a fixture with certain locating buttons and surfaces, which must be ground with the utmost accuracy to maintain their correct relations with each other and with the cylindrical ends. It is necessary only to remove the lathe tool at the conclusion of the turning operation and substitute the Dumore.

Owing to the peculiar form of this casting and the location of the surfaces to be ground, grinding would have been difficult and expensive if not altogether impossible to perform on any other machine. The Dumore did it—*and at a minimum* of expense.

Write for complete information.

DUMORE

High Speed Electric Grinders

No. 1 Dumore Grinder

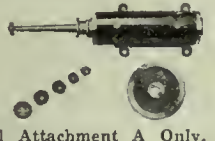
Speed....20,000 R.P.M. ⅛ H.P. Motor
Reach of Arm ..... 4½ in.
Reach of Extension ..... 2 in.
Net Weight ..... 5½ lbs.
Shipping Weight ..... 10¼ lbs.

No. 20G Dumore Centre Grinder

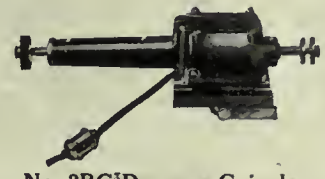
Speed....10,000 R.P.M. 1/6 H.P. Motor
Reach of Spindle ..... 2½ in.
Net Weight ..... 12½ lbs.
Shipping Weight ..... 25 lbs.

No. 2AG Dumore Grinder

Speeds.....10,000 and 30,000 R.P.M.
1/6 H.P. Universal Motor
Reach of Int. Spindle ..... 3 in.
7 Elastic Wheels ..... ⅜ in. to 4 in.
Hardwood carrying case
Net Weight ..... 15½ lbs.
Shipping Weight ..... 28 lbs.

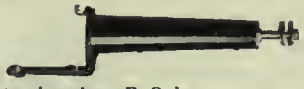


Internal Attachment A Only.
All attachments are interchangeable on No. 2 Grinder.



No. 2BG Dumore Grinder

Speed....10,000 R.P.M. 1/6 H.P. Motor
Reach of Arm..... 10 in.
Net Weight ..... 18 lbs.
Shipping Weight ..... 34 lbs.



Extension Arm B Only.
All attachments are interchangeable on No. 2 Grinder.

No. 2CG Dumore Grinder

Button Die Grinder .... 1/6 H.P. Motor
Speeds .....10,000 and 50,000 R.P.M.
Net Weight ..... 15½ lbs.
Shipping Weight ..... 28 lbs.

Button Die Attachment C
All attachments are interchangeable on No. 2 Grinder.

Aikenhead's, "Canada's Leading Tool Supply House," can fill your requirements promptly. Write for full particulars of these or any other tools for the tool-room or woodworking shop.

No. 3 Multi-Speed Dumore Grinder

Seven Grinding Speeds, 3,600 to 50,000 R.P.M. (¼ H.P. Universal Motor).

Equipment :

12 Emery Wheels 3/16" to 5" in diameter; 2—⅜" Emery Pencils; 5 spindles, 2 wheel arbors and chuck. Reach of largest spindle 6". SEVEN QUICK change pulleys give any speed desired.

Grinding Wheel equipment regularly furnished with No. 3 Multiple Speed Dumore Grinder.

Pulleys and Spindles and Wrenches used in getting the big variation in speed of No. 3 Multiple Speed Dumore Grinder, as specified in No. 3 Multi-Speed Dumore Grinder.

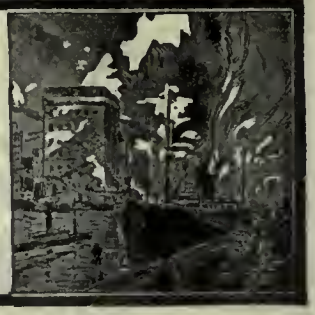
INDUSTRIAL NEWS

NEW SHOPS, TENDERS AND CONTRACTS PERSONAL AND TRADE NOTES



LOOKING FOR BETTER TRADE EARLY IN THE COMING YEAR

REFERENCE to business conditions, present and prospective, is contained in the following opinions:

"In connection with the present and future possibilities of galvanized sheets," said Mr. A. T. Enlow, president of the Dominion Sheet Metal Corporation, Ltd., Hamilton, Ont., "we might summarize the situation as follows: present supply, none; immediate prospective supply, fair; next spring, usual rush.

"It is evident therefore that the wise buyer will order before January 1 and as prices are declining somewhat and may sag a little lower he will lose nothing by so doing.

"There will not be any radical decline, in fact the decline already made is possibly the limit in this swing.

"Underlying basic business is good, especially in Canada, and with the election in the U.S. over on November 2 and the Republican candidate elected, as now seems very probable, business there will also be stimulated and Canada will get the usual reflex glow."

Prices Are Firm

"Your present request for our opinion of the business outlook for the immediate future is rather difficult to answer, but we will begin by saying that we are optimistic," said Mr. L. H. Laythe, sales manager Butterfield & Co., Rock Island, Que.

"We can see nothing in the present situation to cause undue alarm. That we have reached the crest of the long-extended high price movement and are now beginning the descent on the other side cannot be questioned.

"It was all expected, however, by clear thinking business men, and they have only been fooled in that it took longer to reach the peak than was anticipated

"The law of supply and demand is inexorable, and was bound to bring about a readjustment of values sooner or later. and as long as the condition thus brought about is looked upon sanely and all steps and actions in business ventures governing and carried out accordingly, we can see no cause for worry.

"From our own standpoint as manufacturers of small tools, we can see little possibility of any change in prices for the present at least. Radical increases in freight rates, coupled with the fact that raw material in the shape of tool steel and malleable castings shows no reduction, make it impossible for us to reduce our prices now.

"Our advice to jobbers and large users is to buy what they need to keep their stocks well sorted, but not more than can be turned over in a reasonable length of time.

Progressive Swing Next February

"Finally it is our opinion that with the presidential election over in the United States, the crops moved in the Canadian West, a highly satisfactory holiday season at Christmas time, and the usual January first inventories out of the way, that about the first of February of the new year will see things on the progressive swing again, and in a much more healthy condition than at any time since the war began."

NATIONAL CASH REGISTER TO ADOPT PROFIT-SHARING PLAN

The profit-sharing plan adopted by the National Cash Register Company, Ltd., was explained to the employes recently by Frederick B. Patterson, vice-president of the company. The arrangement is characterized by an extreme liberality towards the employes, calling for an equal division of profits between the company and those employes who are not members.

The profits of the company are to be determined by an outside firm of accountants. From the total profits will be deducted an amount equal to six per cent. on the company's investment, not including the value of patents and "goodwill." To offset this six per cent., the employees will receive the highest wages paid for their class of work.

The remaining profits will then be divided equally, the fifty per cent. which goes to the employees being paid in cash as near as possible to the half-yearly accounting dates. The fifty per cent. which goes to the company may be kept in the business for new buildings, machinery, extensions, etc. The employes receive their share unconditionally.

For the operation of the plan the employes are divided into five groups. The first, executives, will receive 12 per cent. of the total profits; the second, foremen, 5 per cent.; the third, job foremen, 8 per cent.; and the fourth, all who have been employed over one month and are not in the first three classes, 25 per cent. Only the fifth group, those who have been in the company's employ less than thirty days, do not share. Each man's share is based on the salary or wages received at present.

Officials of the company expect that the gain in loyalty and production and the decrease of labor turnover resulting from this scheme will make for an increased fall's business. The policy of the company has always been to consider the good of the workers and it has been justified by their success.

Better Times Ahead.—In connection with the annual meeting of the Russell Motor Car Co., Lloyd Harris, president of the Willys-Overland Co., said in referring to the automobile plant on Weston Road, Toronto: "This company has completed the conversion of its plant from aeroplane engine work to automobile work, and during the first six months of the calendar year enjoyed an active demand for its product. Since July 1, in common with other motor companies, it has experienced a contraction of sales and its operations are being carried on at the present time on a reduced basis. It is expected that there will be a renewed demand after the first of the year when the returns from the crops have had time to get into circulation."

Order Engines.—The Canadian Locomotive Company has received an order for four locomotives for the Timiskaming Line, Timiskaming & Northern Ontario Railroad. It is stated that this order will make about 28 engines yet to be completed. At the present time the men in the works are busy on ten locomotives which are being built for the Grand Trunk. It is understood, with the present orders on hand, it will mean that the company will have lots of work until some time after the first of February.

TRADE GOSSIP

Operating at Midland. — Industrial prospects are exceedingly bright for Midland, where there is plenty of hard coal for every home at $18 a ton. The Midland Iron and Steel Company's plant resumes operations this week after a shut down of several months. The plant closed down early in the spring in order to re-line the furnace, but the shortage of coke caused a further cessation.

Erecting Big Plant.—Announcement is made of the sale in Toronto of five acres of land at the corner of Hanson Street and Coxwell Avenue, where there is at present a Grand Trunk Railway siding. Plans and specifications have been prepared for the erection of a modern daylight plant of the best brick and mill type construction. The cost of the building will be in the neighborhood of half a million dollars. The main building will be 500 feet long and 80 feet wide. Upon completion three companies will commence operations in the buildings: Crouse-Hinds Company of Canada; Harvey-Hubbell, and the Hubbell-Mack Machine Screw Company. The new plant is not expected to commence operations until November 1, 1921.

Brantford Firm Changes.—The Brantford Machine & Tool Co., Ltd., has just been incorporated to continue and add to the former business of the Brantford Machine & Tool Co. Mr. Wm. J. Ham, a son of Mr. Jos. Ham, of Ham Brothers, has taken an interest in the concern and will take an active part therein. In addition to their old line of machine and machine tool work, they intend extending and manufacturing a line of garage equipment, such as bench presses, boring tools and small air compressors, and expect to find quite a ready market for same.

Canadian-Detroit Twist Drill.—The Detroit Twist Drill Company has announced the establishment of a manufacturing plant in Walkerville, Ontario, known as the Canadian-Detroit Twist Drill Company. The Detroit Company decided several months ago that the growth of Canadian industry warranted the construction of a plant across the border, and the new company was accordingly incorporated. High-speed drills and reamers will be manufactured and a complete stock will be built up as soon as possible. The nucleus of the Walkerville organization was formed from the personnel of the Detroit plant. About thirty men will be employed at the start. The officers and executives of the new company are as follows: President, Muir B. Snow; vice-president, Lewis H. Jones; treasurer, H. H. Sanger; secretary, P. C. Hill; manager, R. A. B. Goodman; superintendent, Geo. Johnston. Manufacturing operations have already begun, and the first drills are expected to be completed by November 15.

REPORT HAS IT THAT OIL IS TO BE FOUND IN HASTINGS COUNTY

BELLEVILLE.—Startling events of the past few days uncover the possibility of this section of Ontario becoming an important oil producing centre. In Tyendinaga Township, Hastings County, discoveries have been made which are very promising, and one of the largest companies in the world interested in development of oil properties is already in possession of options on over one thousand acres of land in that township. A farmer named Roach, living about three miles from Lonsdale, had a well which he couldn't use on account of the strong oil flavor, so he decided to drill another one. When down forty-two feet on the new well the rush of gas compelled suspension of operations, and there seemed more gas and oil than water. The farmer wanted water badly, but the recurrence of oil indications set him thinking. A relative from Pennsylvania, by profession an oil driller, had visited the farm a year or so ago, and noticing indications of oil, expressed great surprise that the oil scouts who cover the world looking for new fields had overlooked this locality. Mr. Roach came to Belleville and told Mr. John Elliott, manager of the Standard Bank, his story. Mr. Elliott at once communicated with his son-in-law, Mr. Reeves, travelling representative for the General Oil Fields, Limited, of London, England, who is spending a vacation in Belleville, having recently returned from Mexico. What Mr. Reeves saw convinced him that the prospects for an oil field here were excellent; in fact he states that indications are better than anything he saw in Mexico, one of the greatest oil countries in the world.

Mr. Reeves thinks so well of the property that he secured an option on over one thousand acres of land, including the Roach farm. If oil is discovered in quantity the farmers will be paid a good rental besides royalties, which means sudden fortune for a number of farmers in the vicinity of Marysville and Lonsdale.

Geologists have been sent for by Mr. Reeves and a thorough examination of the property will be made at once; if the property proves up as Mr. Reeves thinks it will, he thinks that his company will spend at least a million dollars in development within the next year.

SAY HELP IS NEEDED TO MAKE USE OF THE LOW-GRADE IRON ORES

FORT WILLIAM.—Presentations dealing with aid to the iron industries of this district in Ontario and a lengthy disposition of the doctrines of free trade occupied the time of the tariff commission here.

Sir Henry Drayton, chairman, Hon. G. D. Robertson and Hon. S. F. Tolmie were in attendance and the first witness was J. E. Marks of Port Arthur, who presented the case for the imposition of a bounty of at least 50 cents per ton upon iron ore mined in Ontario. He urged that the former bounties given for iron smelted from Canadian ores failed in their effect because they went to the smelter and not to the miner. He adduced figures in an effort to show that there were millions of tons of ore available close to railway and navigation facilities which required aid in order to be merchantable. He urged that the Dominion of Canada ought to cause the Canadian iron to be mined and utilized in Canadian furnaces.

The chairman asked whether he did not think that, with an apparent surplus of $100,000 the iron industry could not be trusted to take care of development without aid.

Mr. Marks replied that the raw material of the iron manufacturers was largely the half-finished product from the States.

To a remark by the chairman that the British Columbia bonus had apparently not been effective in building up iron industries, Mr. Marks said that the smelters got all the bonus and not the miner.

The chairman asked concerning the deleterious elements in the local iron ores and was told that the ores were free of all injurious elements except sulphur and this was disposed of by roasting, which was successfully done with the ore from the Atikokan range.

Dr. R. J. Manion, M.P., said that he had not intended to speak but he had advocated some form of aid to the iron industry on the floor of the House, and one reason that he would approve of the bounty was that if it was not earned by production the bounty would not be paid. He believed that Canada ought to produce many of the steel products which she now imports.

Owners of Iron Lands

J. J. O'Connor spoke as representative of owners of iron ore lands, and said that the time was coming soon when the lower grades of ore would be needed, and it was high time that Canada attempted to make use of her low grade ores. He pointed out that one American firm had spent $750,000 in experimenting with magnetic substances on the ranges in Minnesota and now began to install a three million dollar plant to utilize low grade iron ore.

Locomotive, Automobile, Aeroplane, Gun and Machine Parts

subject to maximum shocks of great frequency or torsional strains, are first forged. WHY? Because forging increases their physical properties, rearranges the structure to withstand stresses in any desired direction, and gives each portion the required amount of working.

At the proper temperature the flutes of RICH TOOLS are first forged and twisted. The result is a blank thoroughly uniform in every part and of superior physical properties to the bar from which it was made.

NOT WELDED, BRAZED OR BUILT UP—MADE IN ONE PIECE of the most suitable and best High Speed Steel of the proper composition — every operation and process is conducted with care and judgment.

IT IS UNNECESSARY TO TELL YOU THAT THIS DRILL WILL PRODUCE MAXIMUM SERVICE—IT IS BUILT FOR IT.

Taper Shanks, Standard and Oversize. Straight Shank, Long and Short Set.

We also manufacture High Speed Bridge Reamers, Countersinks, Track and Bonding Bits, Rivet Sets, etc.

TO PROVIDE EDUCATION FOR THE OPERATING ENGINEERS IN ALBERTA

A DELEGATION from the steam Engineers in conference in Edmonton, consisting of E. E. Howard, Edmonton, F. J. Dobson, Edmonton, and W. G. Singer, Red Cliff, in the absence of the Minister met Mr. J. T. Ross, the Deputy Minister of Education, and D. A. Campbell, Provincial Director of Technical Education at the Department of Education, and pointed out the great need of providing instruction to the thousands of men in the province who have charge of boilers and engines in manufacturing and industrial establishments, in large business houses where elevators are used, in mining centres, in lumber mills, and in power plants.

It was pointed out that a technical knowledge of steam engineering, in addition to practical experience, is essential to the man in charge of such pivotal positions throughout the province. All are required to hold provincial certificates, and during the past two years the following numbers were issued by the Steam Boilers Branch of the Public Works Department, to men operating various types of portable and stationary boilers and engines.

	1918	1919
First class	6	4
Second class	26	18
Third class	135	142
Traction final	163	101
Firemans' final	55	45
Provisional	447	345
Renewals (Provisional)	177	209
	1,009	864

At the present time there are over two thousand five hundred portable and traction boilers in the province available for use, and the stationary boilers number seven hundred and forty, located in three hundred and thirty-six plants. All the men in charge of these boilers must be holders of provincial certificates obtained as the result of examinations, covering a wide range of practical scientific and technical knowledge.

The deputation was informed that the present policy of the department of education would assist the Steam Engineers in a manner similar to that in operation for the miners.

It was suggested that even classes for steam engineers might be organized at Edmonton, Calgary, Medicine Hat, Lethbridge, Red Cliff, Drumheller, and in the Crow's Nest Pass. These classes would be under the control of the local school boards. Provincial grants are already available, and will be paid to boards which conduct classes in these subjects.

The deputation was told that the department was aware that a real need existed and had announced steam engineering as a type of work which fell properly within the scope of the new provincial institute of technology and art at Calgary. The Steam Engineering department of this institute might undertake instruction by correspondence, to steam engineers located in all points in the province. The whole matter will be given further consideration upon the return from the east of the Hon. George P. Smith, Minister of Education.

The delegation left with the intention of taking advantage of the present provisions which enable school boards to supply this type of education in evening classes to adults.

The city of Lethbridge already has such a class organized.

BUSINESS OPPORTUNITIES

By communicating with this paper and mentioning key numbers, information can be obtained by firms interested in the following lines:

2035. MILD STEEL BOLTS AND NUTS.—Importers in Scotland are desirous of getting into touch with Canadian manufacturers of these in small sizes from ¼ in. thick up to ½ in.

2036. MACHINE TOOLS.—Engineering apparatus and tools, instruments for controlling heat treatment of metals, industrial machinery metals, special steels, electrical heating appartus, mica, etc. A most important limited company at Milan with very good business connections in Italy and abroad wishes to do business with Canada in the foregoing.

2045. A Trinidad commission agency wish to make connection with Canadian exporters of agricultural and artisans' tools.

2033. IRON AND STEEL BARS. — Firm in Scotland is open to receive quotations for the following: each five tons; iron or steel bars:
1½ x 1½ x ¼-ins. Angle x 20 to 21-ft.
2-in. x 2-in. x ¼-in. Angle x 20 to 21-ft.
3-in. x 3-in. x ¼-in. Angle x 18 to 20-ft.

2034. GALVANIZED SOLID WIRE AND BARBED WIRE.—Firm in Scotland is open to receive quotations for the following: 3 tons No. 6 galvanized solid wire; 3 tons No. 7 galvanized solid wire; 2 tons No. 8 galvanized solid wire; 4 tons galvanized barbed wire, 4 points 6-inch. apart.

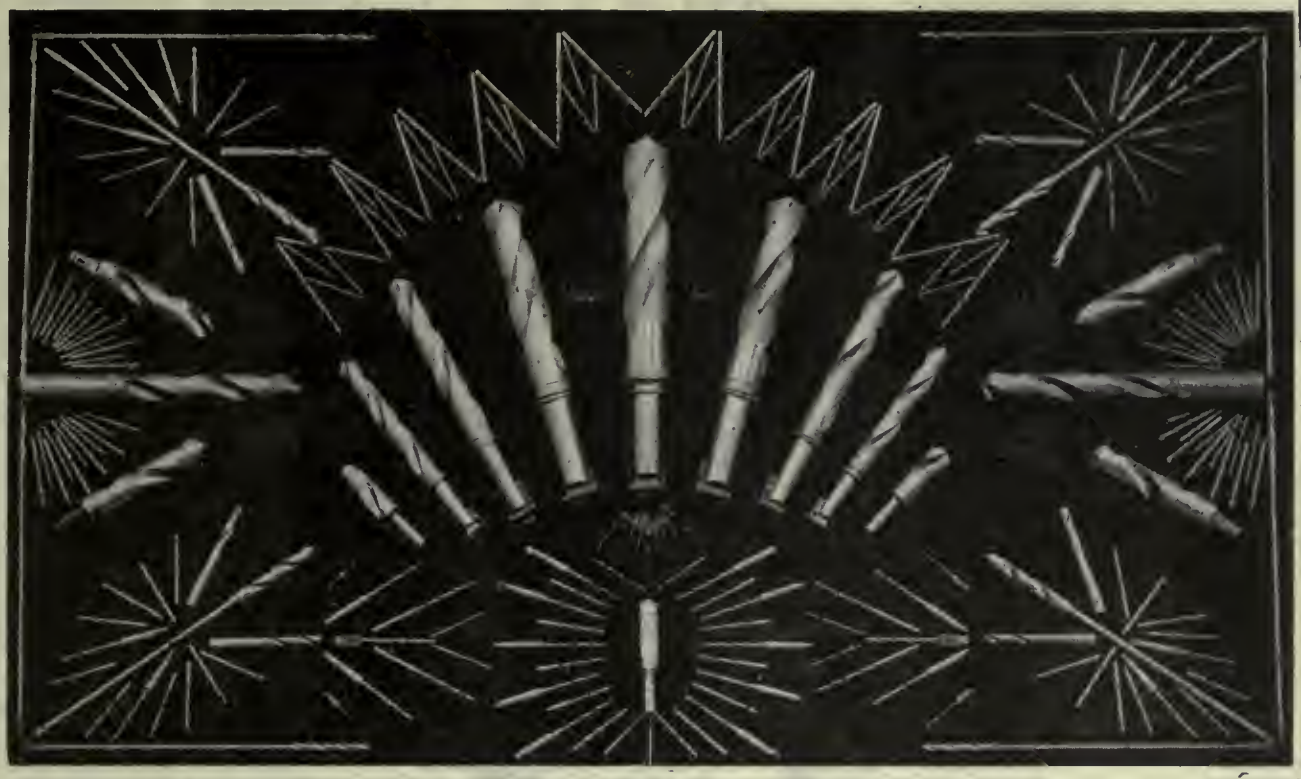
Starts British Branch.—The Simonds Canada Saw Company, Limited, of Montreal, Quebec, have just secured a charter and established a new company in Great Britain, to be known as Simonds Saws, Limited. An office and shop has been opened at 53 Bayham, Camden Town, London, N.W. The shop will provide for maintenance and repairs of saws, machine knives, and other edge tools produced by the Simonds Company. Guy A. Eaves, formerly connected with the Fitchburg, Mass., plant of the company, has assumed the duties as office manager, and Leon E. Wilbur, who has covered the Great Britain territory since his discharge from the army in France, will be associated with him. The Simonds Manufacturing Company now maintains plants in Fitchburg, Mass., Chicago, Ill., Montreal, Canada, and a steel mill at Lockport N.Y.

STAINLESS OR RUSTLESS STEEL

Stainless or rustless steel consists essentially of an alloy of iron and chromium, containing usually 0.1-1 per cent. carbon and 12-14 per cent. chromium. It is produced in crucibles or electric furnaces, owing to the tendency of the chromium to oxidize at the melting point. The metal is cast in the usual manner into ingot molds, and the ingots are forged or rolled into bars or sheets. The material can be forged fairly readily into various forms if heated to a bright orange temperature; and if after forging the metal is allowed to cool in air, it will be found to possess good cutting qualities. Quenching in water enhances the hardness to a considerable degree, especially if the steel contains more than 0.4 per cent. carbon, but oil quenching gives the best results. This steel resists formation of scale during forging to a great extent, and is therefore adapted to high-temperature uses, such as engine valves, distilling apparatus, etc. When ground and polished the material resists tarnishing to a remarkable degree. It is slowly attacked by dilute or strong sulphuric and hydrochloric acids, practically unaffected by nitric acid, and is unaffected by nearly all the fruit acids and strong vinegar.

Automobile engineers in all parts of the world will await with keen interest the receipt of a report recently completed by the research committee of the Institution of Automobile Engineers of Great Britain. The report deals with the physical properties of the ten automobile steels standardized according to the recommendations of the British Engineering Standards Association. Colored charts will be given showing the result of tests of tensile strength, hardness, and other qualities as affected by heat treatment. Automobile construction is becoming more and more scientific every day, and it is evident that British designers intend to keep in the forefront of the advance which depends upon a minute knowledge of the materials employed. Only a limited number of reports will be printed and early application is therefore advised.

In advising an engineer as to the best means of treating an old oak staircase which had been attacked by woodworm, "The Builder" says that the most effective means of treating oak work when attacked with woodworm is to give it several coats of paraffin, well soaked into the wood. This should be done by a careful workman, making quite sure that every hole has been well soaked with the paraffin; if treated with paraffin it does not damage the oak, but has a tendency to improve the color.



Morrow Drills

Drills for Every Purpose

No matter what the drilling operation in your shop may be, you can get a MORROW DRILL to meet it—MORE HOLES with LESS RE-GRINDING.

The Tube Company of Canada

233 Dufferin St. TORONTO, ONT

CALCULATING DIMENSIONS ON 100 H.P. H. R. T. BOILER

Continued from page 395

And for outer and middle rows

$$3\text{-}10P+d$$
$$=.3\times 6.68875+.875$$
$$=2.00625+.875$$
$$=2.881.$$

Of course these dimensions are all the minimum allowable, and if we exceed them it will not matter.

For the thickness of the metal forming the straps we have

$$\frac{5\times T\times (P-d)}{8\times (P-2d)} = \text{Thickness.}$$

Then

$$\frac{5\times 7(6\ 11\text{-}16-⅞)}{8\times 16(6\ 11\text{-}16-7\text{-}4)}$$
$$=\frac{5\times 7\times 93\times 16}{8\times 16\times 16\times 79}$$
$$=.321 \text{ inches.}$$

This is practically 5-16, but it would be just as well to use ⅜ plate, and thus have a margin over size to allow for wasting, and to make a better caulking edge.

The dimensions for the joint will therefore be:

Pitch outside row, 6 11-16 inches.
Pitch inner rows, 3 11-32 inches.
Diameter of rivets, ⅞ inch.
Thickness of straps, ⅜ inch.

Minimum distance between outer and middle rows, 2.33 inches.

Minimum distance between inner and middle rows, 1.66 inches.

Minimum diagonal pitch between inner and middle rows, 2.35 inches.

Minimum diagonal pitch between outer and middle rows, 2.88 inches.

The width of straps will be the sum of the distance between the three rows of rivets, plus three diameters, multiplied by two.

The accompanying dimensioned sketch shows all the particulars.

Company Reorganized.—The reorganization of the Mami Axle Co., Ltd., St. Stephens, N.B., has just taken place. This is one of the oldest companies on the coast, and has been operating for about 25 years. The capital has been increased from $50,000 to $200,000, and it has been decided that they will rebuild the forge plant which was burned down last July. This building will be a modern forge plant with the purpose of making axes. It will be 60 ft. x 160 ft., and of steel and brick construction. A full line of equipment will be installed. The following are the new board of directors: Chas. E. Henstis, president; James Arnold, Brockville, vice-president, and J. A. Briggs, secretary-treasurer. The other gentlemen are: Hon. George P. Graham, Brockville; T. J. Dillon, and B. J. McCormack, of Welland.

WILL IT WORK

Continued from page 397

fostered this chemical delusion and have educated the public to buy chemical analyses and test bar evidence; the public wanted it, and got it. The whole thing may be summed up in the following words: production, and still more production; composition, accurate to the dot, but quality be hanged. Craftsmanship and skill have given way to arbitrary formulae and the pseudo scientists are happy.

If the consumer will be guided by the question: "will it work?" he will devise simple, practical, sensible tests. He will employ practical, experienced inspectors. He will seek to test material for its suitability to the work at hand, and not merely for its composition.

In the series of articles to follow I will attempt to lay before our readers conditions in the metal world as they are and not how some people think they ought to be.

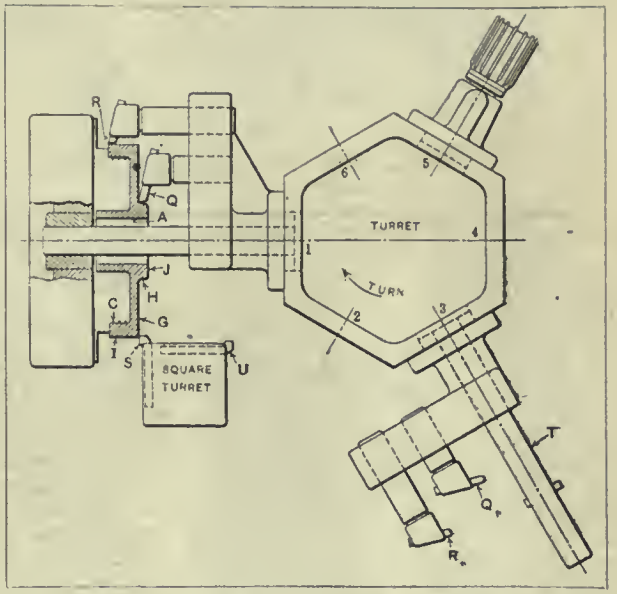
MANUFACTURING NEWS

Vol. XXIV. No. 19 November 4, 1920

A Great Variety *of* Work Done *on* the Turret Lathe

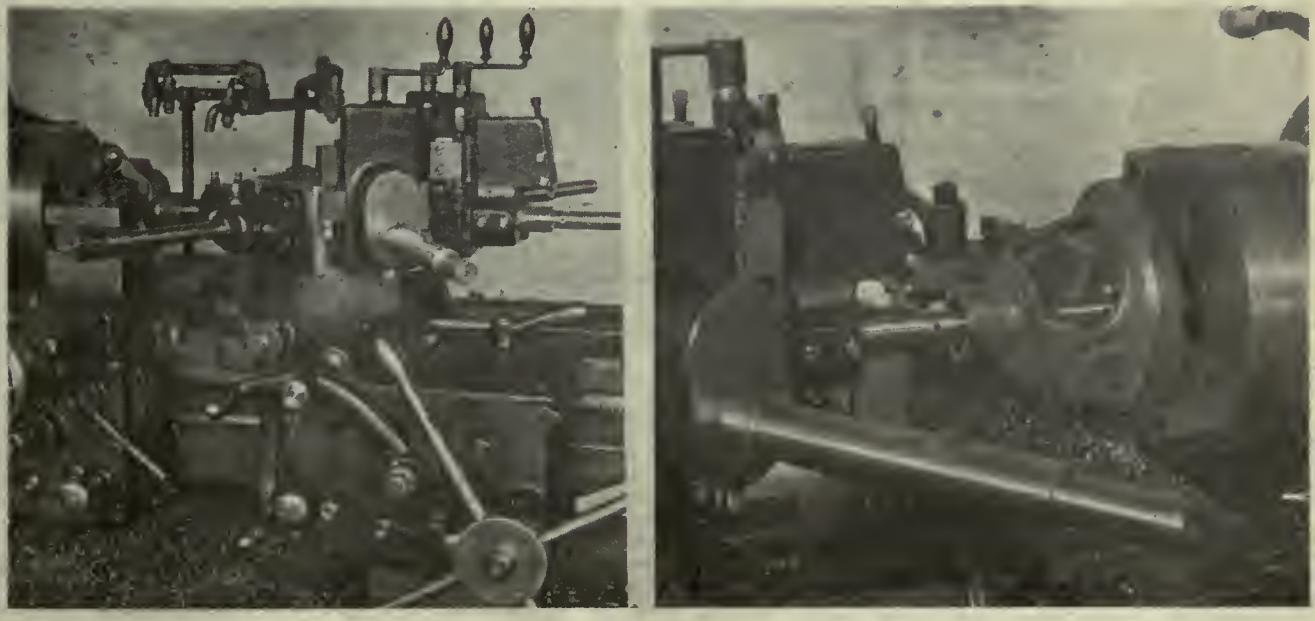
Tool layouts for a Gear Case, friction pulley, semi-steel casting, steel spindle, and other parts are shown. These layouts should be filed for future reference.



IN our previous article dealing with the practice of the Foster Machine Co., Elkhart, Ind., we showed the finishing of gear blanks, friction cores, etc., and to those who did not see it we suggest their looking it up. In the present article, which is the last one, we will go further into the question of tool layout and describe tooling equipment as used for machining automobile differential gear cases, semi-steel castings, chuck bodies, friction pulleys, and bar stock parts.

Differential Gear Case

The case shown at Fig. 1 is machined on a No. 1B universal turret lathe, the machined portion being shown by heavy lines. This portion is made of malleable iron, and is machined in 6.4 minutes. A machine equipped for this operation is illustrated at Figs. 3 and 4. A good idea of the set-up can be obtained from these views, Fig. 4 showing a close up view of both the work and tools. This photo-



FIGS. 3 AND 4—THE VIEW TO LEFT SHOWS TOOLS REQUIRED IN FINISHING DIFFERENTIAL GEAR CASE. VIEW TO RIGHT IS A CLOSE UP OF FIG. 3 FROM THE REAR.

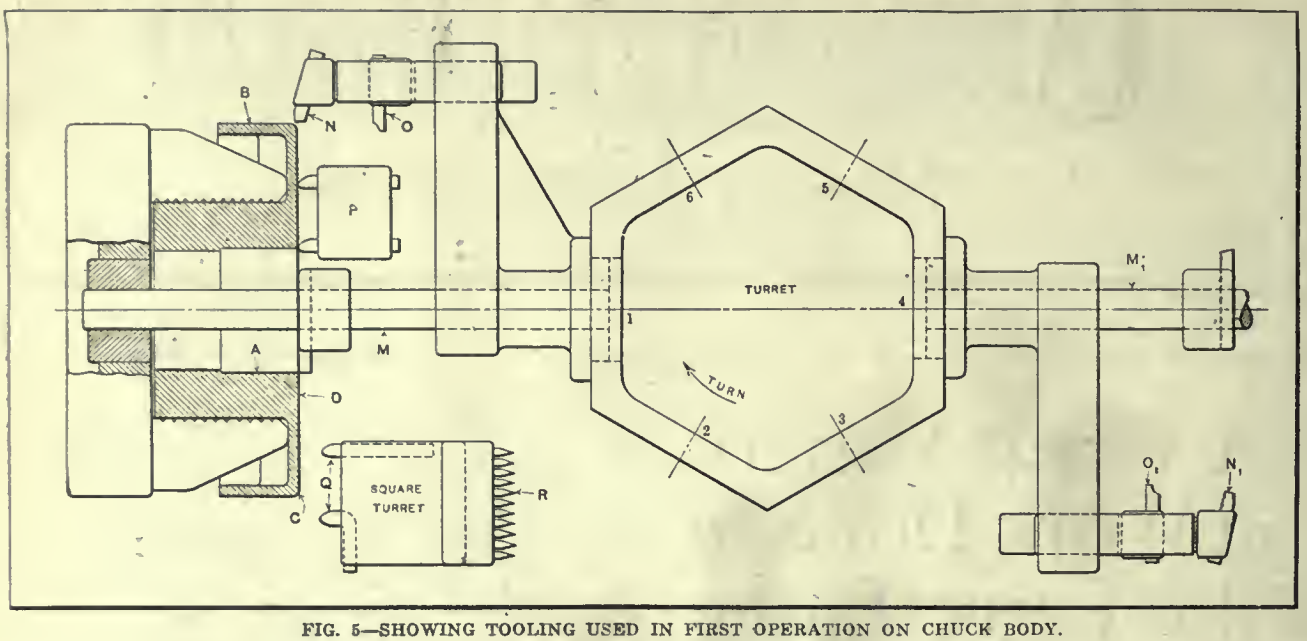


FIG. 5—SHOWING TOOLING USED IN FIRST OPERATION ON CHUCK BODY.

graph was taken from the rear of the machine.

The various steps of the operation follow in sequence. The casting is placed in a three-jaw air chuck provided with special jaws that grip the work along the periphery of the flange. The chuck is also provided with a guide bushing to suit the pilots of the various tools mounted in the turret. The holes A (see Fig. 1) are rough-bored, and surface B is turned by the tools held in double cutter piloted boring bar, this bar being mounted in a turning slide tool in the turret. The surface C is rough-turned by a tool held in the square turret, and the surface D is rough-faced by another tool in the same turret.

The hole A is next finish-bored and surface E is faced by a double cutter piloted boring bar held in a turning slide tool mounted in the turret. The surface F is rough-faced by a tool mounted in a piloted bar which is held in the turret, and the surface F is finish-faced by a tool mounted in another piloted bar, which is also held in the turret.

Holes A are now reamed by an expansion reamer mounted in the turret. The chamfer G is produced, and corner H is formed by tools mounted in a piloted bar held in a sliding tool in the turret. The casting is now removed from the machine as this completes the operations on this case.

Machining Cast Steel Chuck Bodies

The chuck body, illustrated at Fig. 2, and which is made of cast steel, is completed in two operations, the machined portions being marked in heavy lines. The time of machining is 1 hour 21.8 minutes, and the piece is completed on a No. 3B universal turret lathe. The layout of the tooling equipment as used in the first operation is shown at Fig. 5. This operation requires 42.2 minutes and the sequence of steps are as follows:

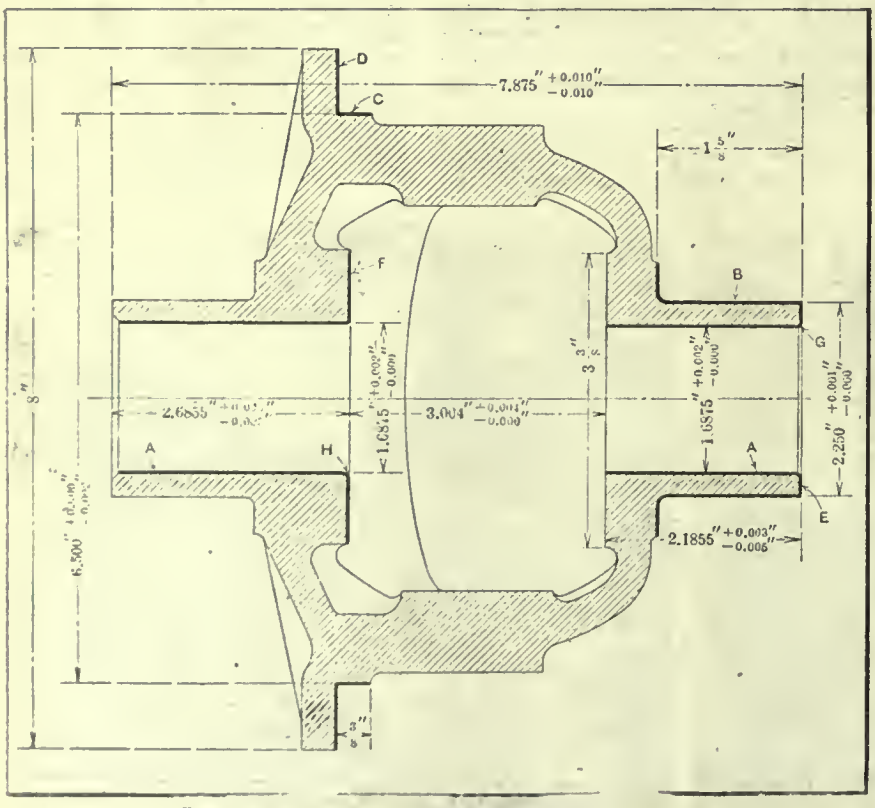

FIG. 1—DETAIL OF DIFFERENTIAL GEAR CASE.

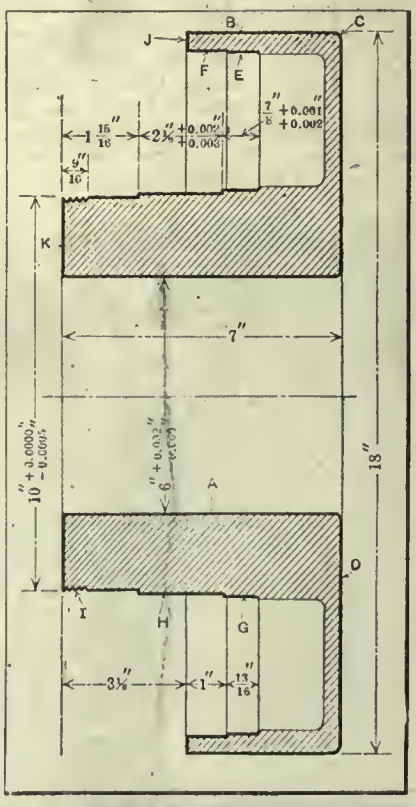

FIG. 2—VIEW OF THE CAST STEEL CHUCK BODY.

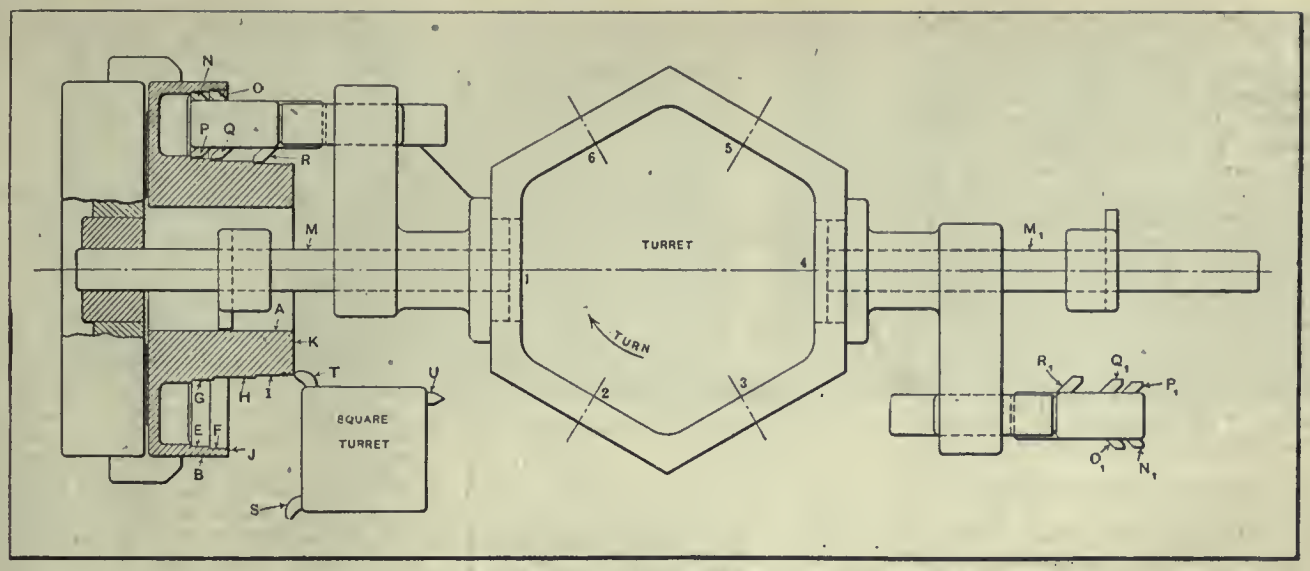

FIG. 6—THE FINAL OPERATION ON THE CHUCK BODY.

The work is mounted on a chuck equipped with three corrugated and hardened jaws that grip it on the rough surface of the hub. One half the length of hole A is rough-bored by the cutter held in piloted boring bar M. The surface B is rough-turned by tool N, and corner C is rough-turned by tool O. These tools and bars are held in the multiple turning head at position 1 of the turret.

The surface D is now rough-faced by the tools in post P on the rear of the cross-slide. The portion of hole A rough-bored in the previous step is now finish-bored by the cutter held in boring-bar M; surface B is finish-turned by tool N_1, and the corner C is finished-formed by tool O_1. These tools and bar are mounted in the multiple turning head at position 4 of the turret.

At the same time the surface D is finish-faced by tools Q, which are held in the square turret. Concentric grooves are cut on surface D by tools R, which are also mounted in the square turret. The casting is now removed from the chuck, the operation being completed.

The second operation on the chuck body is completed in 39.6 minutes. A layout of the tooling is shown at Fig. 6, and the steps are as follows. The work is mounted in a three-jaw chuck, which grips it on the previously finished surface B. The half length of hole A that is still unfinished is rough-bored by the cutter held in bar M. The surface E is rough-bored by tool N; surface F is rough-bored by tool O, surface G is rough-turned by tool P, surface H is rough-turned by tool Q, and the surface I is rough-turned by tool R. All these tools and the bar M are mounted in the multiple turning head in position 1 of the turret.

At the same time surface K and J are rough-faced by tool S, this tool being held in the square turret. The portion of hole A just previously rough-

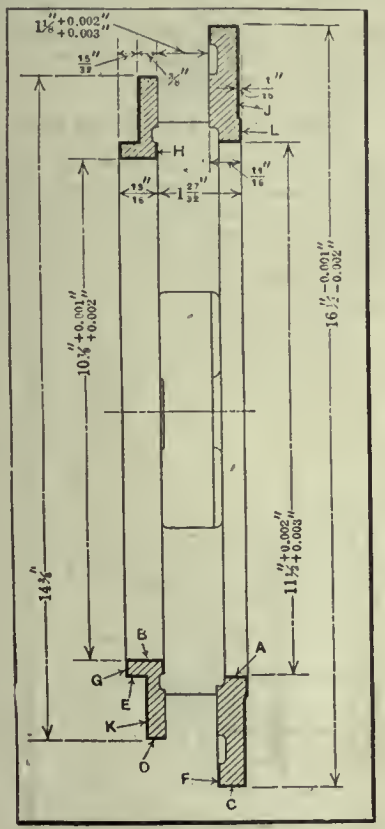

FIG. 7—THIS SHOWS THE SEMI-STEEL CASTING MENTIONED IN TEXT.

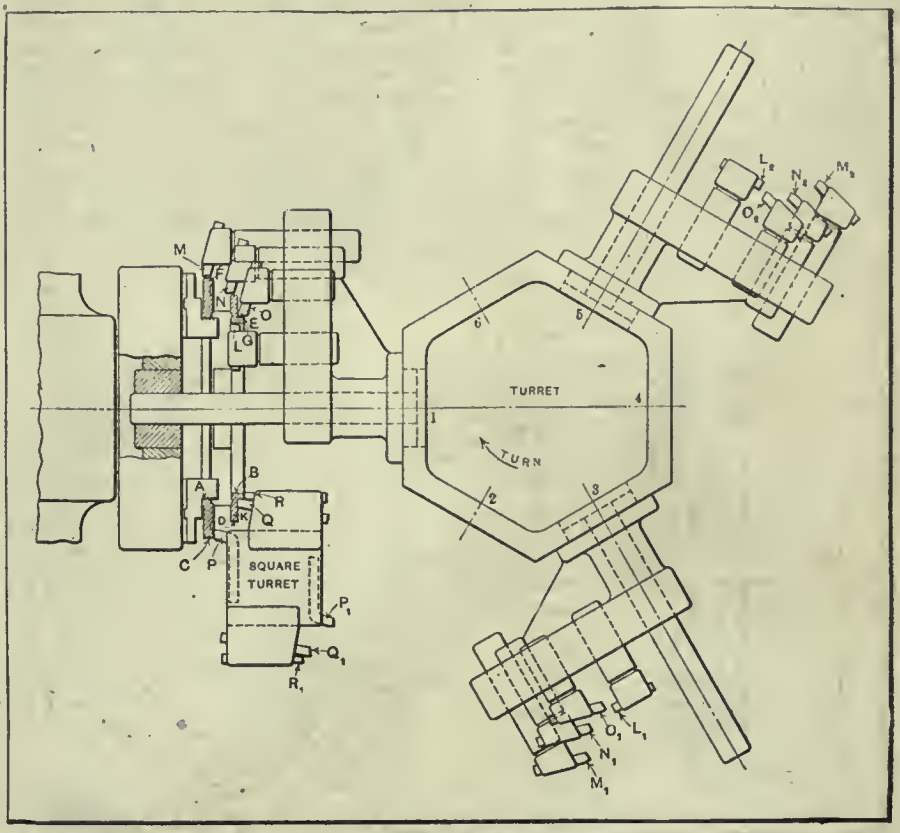

FIG. 8—THE TOOLING USED FOR CASTING SHOWN AT FIG. 7.

bored is now finish-bored by cutter held in bar M_1.

The surface E is finish-bored by tool N_1, surface F is finished-bored by tool O_1, surface G is finish-turned by tool P_1, surface H is finish turned by tool Q_1, and surface I is finish-turned by tool R_1. All the above tools and bar are held in the multiple turning head at position 4 of the turret.

At the same time, surfaces K and J are finish-faced by tool T, which is held in the square turret. The threads of surface I are now cut by tool U, mounted in square turret, and which is used in conjunction with the screw-cutting attachment. This completes the operation and the work is removed from the chuck.

Machining Semi-Steel Castings

At Fig. 7 is shown a semi-steel casting which is machined in two operations on No. 3B universal turret lathes. Both operations are completed in 16.5 minutes. The tool equipment layout is shown at Fig. 8. Following are the steps taken:

The work is placed in a three-jawed chuck equipped with corrugated and hardened false jaws which hold the work by bearing against hole A. The hole B is rough-bored by tool L, the surface C is rough-turned by tool M, the surface D is rough-turned by tool N, and the surface E is rough-turned by tool O. All these tools are mounted in the piloted-turning head at position 1 of the turret.

At the same time surface F is rough-faced by tool P, surface K is rough-faced by tool Q, and surface G is rough-faced by tool R. These tools are held in the square turret.

The hole B is again bored by tool L_1, and surfaces C, D, and E are again turned by tools M_1, N_1, and O_1, respectively, all of these tools being mounted in the piloted multiple turning head in position 3 of the turret. At the same time surface F is finish-faced by tool P_1, surface K is finish-faced by tool Q_1, and surface G is finish-faced by tool R_1,

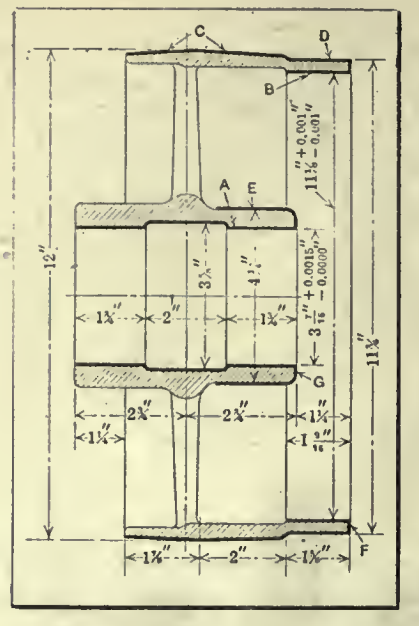

FIG. 10—SHOWING THE FRICTION PULLEY.

these being tools mounted in the square turret.

The hole B is now finish-bored by tool L_2, and surfaces C, D and E are finish-turned by tools M_2, N_2, and O_2 respectively, all of which are mounted in the turning head in position 5 of the turret. The casting is now removed from the chuck.

The remaining tool layout is shown at Fig. 9. This operation is completed in 6.6 minutes, and the sequence of steps are as follows: The work is mounted in a three-jaw chuck that grips it along the previously-finished surface C. Hole A is rough-bored by tool S, and surface H is rough-faced by tool T, these tools being mounted in the piloted multiple turning head held at position 1 of the turret. The surfaces J and I are mounted on a tool block on the rear of the cross-slide. Hole A is now finish-bored by tool S_1, and surface H is finish-faced by tool T_1, these tools being mounted on the piloted multiple turning head at position 4 of the turret. The work can be noted by the dot-and-dash line. This completes the operation and work is removed from the chuck.

Machining Friction Pulleys

The cast iron friction pulley depicted at Fig. 10 is machined in one operation on a No. 2B universal turret lathe. A machine provided with the tooling used is shown at Fig 11. This illustration shows the rear of the machine, and the photograph was taken after the pulley mounted on the lathe had been partially machined. The series of steps in this operation is taken in the following order: The pulley is placed in a three-jaw Barker chuck, equipped with special jaws that bear against the inside of the pulley rim. This chuck is also provided with a guiding bushing to suit the pilots on the various tools mounted in the turret.

Hole *A* and surface *B*, Fig. 10, are rough-bored, and surfaces *C*, *D*, and E are rough-turned by tools mounted in a multiple turning head which is held in the turret, while surfaces F and G are rough-faced by tools mounted in the square turret. Hole *A* and surface *B* are finish-bored and surface *D* is finish-bored by tools mounted in a multiple turning head held in the turret, while crown *C* is finish-turned by a tool held in the square turret and a tool mounted on a tool-holder on the rear of the cross-slide, these tools being operated in conjunction with a taper attachment on the rear of the lathe. The relief in hole *A* is bored by a cutter held in a boring-bar which is mounted in a sliding tool attached to the turret. Hole *A* and surface *B* are reamed by a special combination expansion reamer mounted in the turret. The finished pulley is now removed from the lathe.

Producing a Part From Bar Stock

Fig. 15 shows the drawing of a part machined from bar stock in one operation on a No. 1B universal turret lathe.

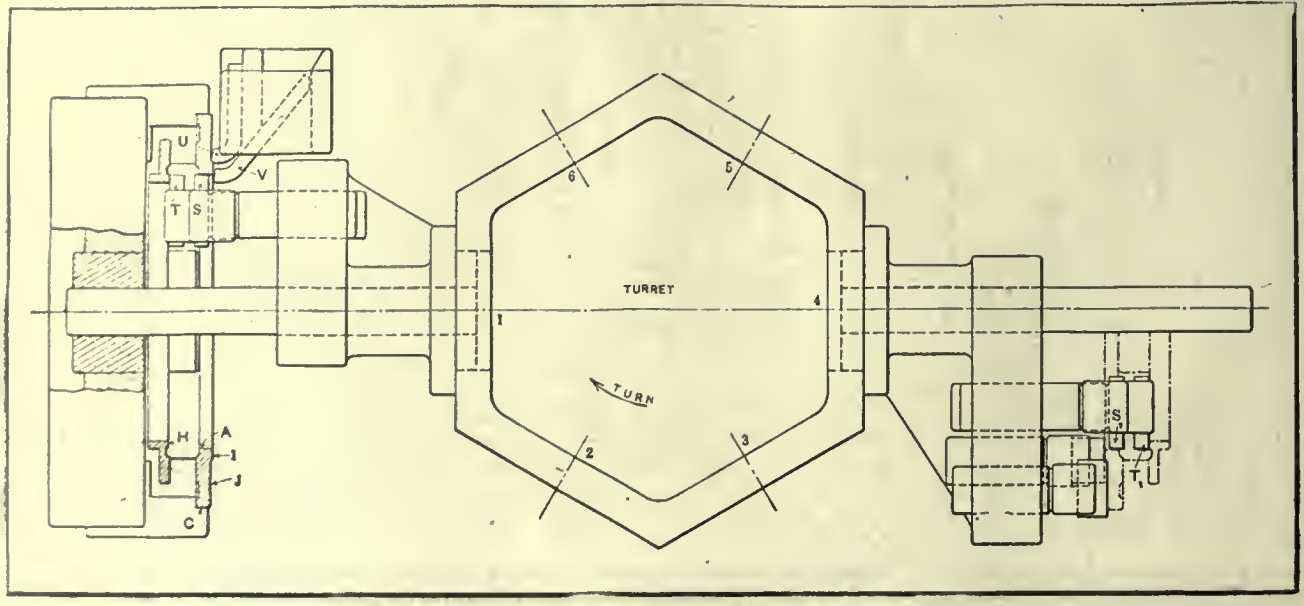

FIG. 9—THE SECOND OPERATION ON THE PIECE SHOWN AT FIG. 7.

FIG. 11—FINISHING THE FRICTION PULLEY SHOWN AT FIG. 10.

FIG. 12—PRODUCING THE PART SHOWN AT FIG. 15.

A machine engaged in producing one of these pieces is shown in Fig. 12. This illustration shows quite clearly the method employed in the manufacture of this part. The steps in this operation are taken as follows: The stock is fed to a stop on the turret and then held by means of an automatic chuck. Hole *A*, Fig. 15, is drilled by a drill mounted in a flanged tool-holder held in the turret. Hole *A* is chamfered as shown, by means of a taper reamer mounted in a flanged tool-holder held in the turret. Surface *B* is rough-turned by a tool held in the square turret. A revolving centre which is mounted in the turret is placed in hole *A* during this and the succeeding operation so as to support the work adequately during these operations.

All the remaining unfinished surfaces except surface *C* (which is not finished, the part being made from cold-rolled steel) and the surface produced when the piece is cut from the stock are finish-formed by means of a special forming tool that is held in the rear tool-holder. The completed piece is cut off from the stock by a tool held in the square turret.

Machining a Long Steel Spindle

The steel spindle illustrated in Fig. 13 is machined in two chuckings on No. 2-B universal turret lathes. It will be noted that this piece is over four feet long, while the greatest diameter is only 2¼ inches. Both operations on this spindle are performed in 35.7 minutes. A layout of the tooling equipment used in the first operation is shown in Fig. 14, this operation being performed in 19.9 minutes. There are no reference letters shown on the various surfaces of the work in Fig. 14, and so Fig. 13 must be referred to in following the method of manufacturing this part. The various steps in the operation are taken in the following order:

The stock is fed up to the stop on the turret corner between Sides 1 and 6, which permits somewhat more than one-half of the length of the piece to project beyond the chuck. Surfaces A and B are rough turned by the tool held in the single cutter turner in Side 1 of the turret, and surfaces C, D, and E are rough turned by tool T, which is held in the square turret.

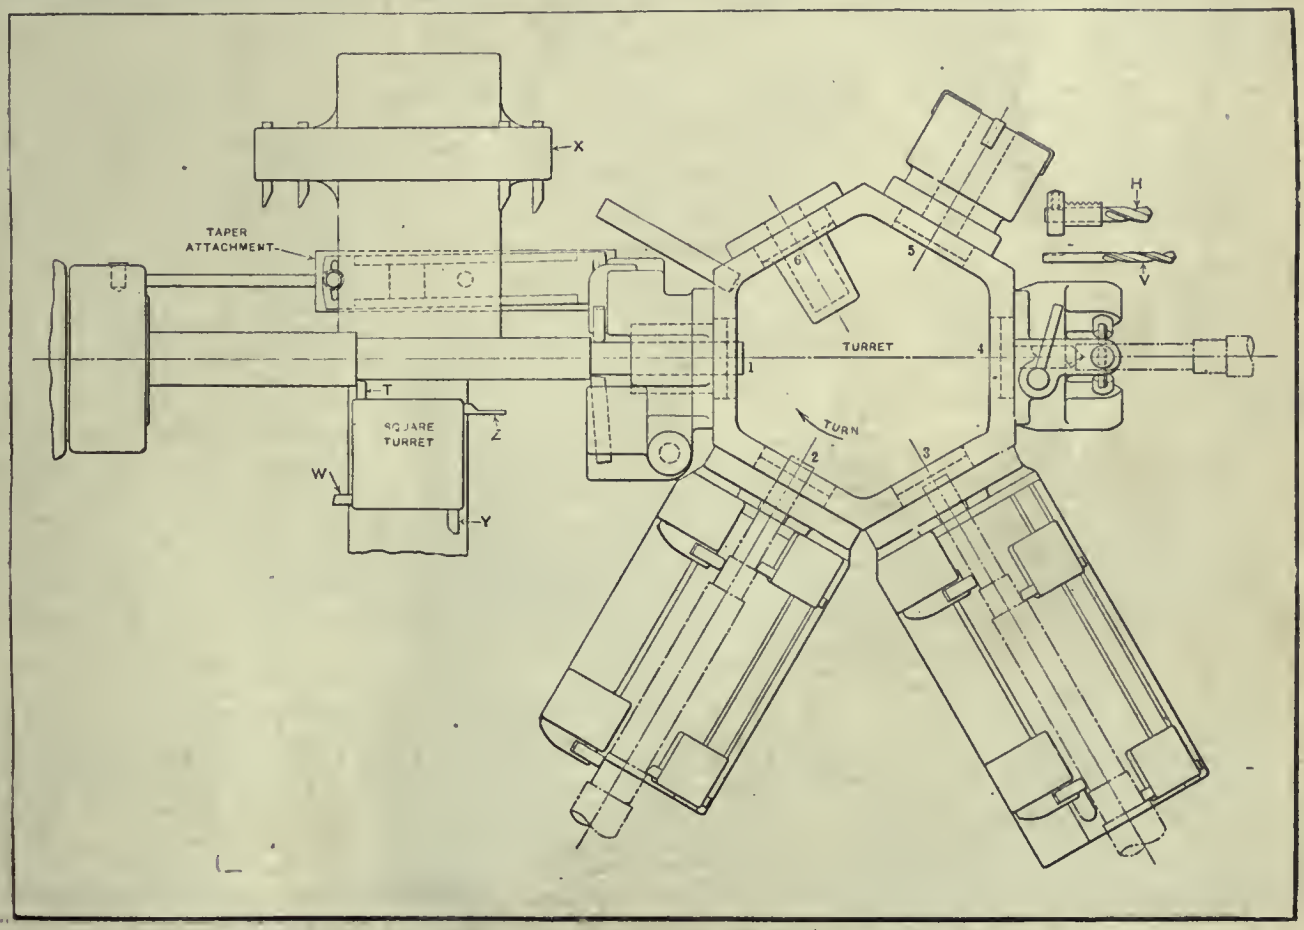

FIG. 14—TOOLING EQUIPMENT USED TO MACHINE THE SPINDLE SHOWN AT FIG. 13.

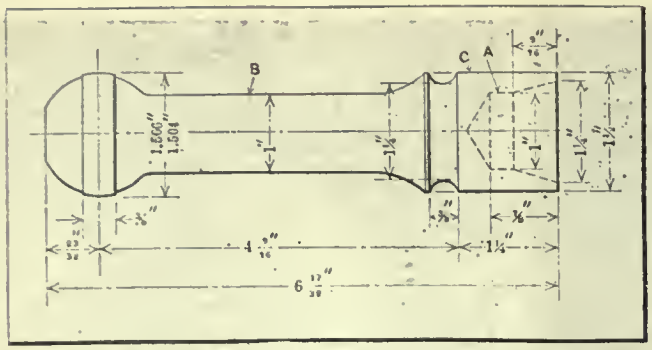

FIG. 15—PIECE FORMED FROM BAR STOCK IN ONE OPERATION.

Surfaces A and D are finish-turned and surface C is finish-straight-turned by the tools held in the multiple cutter turner in side 2 of the turret. The work is indicated in this turning fixture by dot and-dash lines. At the same time, surface F is turned by tool T. Surfaces B and E are finish-turned by the tools held in the multiple cutter turner mounted in side 3 of the turret. The work is also indicated in this fixture by dot-and-dash lines. A centre is drilled in end G by the roller-rest centering tool in side 4 of the turret. Then the centreing tool is replaced by drill H and hole H is drilled after which drill H is replaced by the tap drill V and hole I is drilled in preparation for a tapping operation which is performed in this end by hand.

The centering tool is then replaced in the fixture. While the centering holes are being drilled surface C is rough taper turned by tool W mounted in the square turret which is used in connection with the taper attachment. While end G of the shaft is still supported by the centering tool in position 4 of the turret, the necking tools mounted in fixture X on the rear of cross-slide are first located, then the four grooves between the various surfaces on the right hand end of spindle are turned by these tools.

The threads on surface E are now cut by the self-opening die head mounted in position 5 of the turret. The stock is fed up to the special stop in position 6 of the turret, which permits slightly more than the total length of the spindle to project beyond the chuck.

While the stock is supported in the stop just mentioned, the shaft is chamfered at end O by tool Y, which is held in the square turret, so that the single cutter turner which turns surface I in the succeeding operation can be properly started.

While the piece is still supported in the stop in position 6 of the turret, the spindle is cut off from the stock by tool Z, which is also held in the square turret. The projecting end of the stock is chamfered at the same time by tool Z so that the single cutter turner used to turn this end of the succeeding spindle can be correctly started.

The second operation on the spindle consists of machining the left hand end, and is performed in 15.8 minutes. The work is held in a chuck equipped with a collet bushing that grips the work around the previously finished surface F. The tooling equipment used in this operation is identical with that shown at Fig. 14, because surfaces J, K, L, M, and N, and holes P and Q, are of the same dimensions as surfaces A, B, C, D, and E, and holes H and I, which were machined by means of this tooling equipment. The only difference between the two operations is the machining of surface F, which is performed in the first operation. For this reason a detailed description of the steps in the second operation is not necessary. This concludes the present article and readers will do well to preserve these various layouts for future reference.

IDENTIFYING THEIR PRODUCT

The Skinner Chuck Company, Inc., of New Britain, Conn., have recently joined the ranks of American manufacturers who identify their products with a trade mark. The new trade mark of this company, while very simple, is really unique. It shows an alligator in the form of the letter "S," superimposed on a solid black circular background, with the words "Skinner Chucks" drawn around the outside. The alligator was chosen after long deliberation as the symbolic figure best suited to the exploitation of their idea, because both the alligator and their chucks have strong jaws and long life.

The trade mark will be stamped on all their chucks in the future to indicate that the same was made and is guaranteed by the company. A special advertising campaign extending over two months in prominent metal-working publications and other publications of interest to chuck users is the vehicle by which the company will make the trade mark known to the present and potential buyers of their products.

A NEW RADIO STATION

A new wireless station at Siasconset, Nantucket Island, Mass., has been opened by the International Radio Telegraph Company. The site is a historic one, from a wireless standpoint, for temporary stations have been located here ever since the beginnings of wireless, but permanent, commercial service is now established at this point.

This new station, which is the fifth to be opened by the company, is now the nearest one on the Atlantic coast for vessels coming from Europe. Its working radius is more than 250 miles by day and 1,000 miles by night. It has direct cable connections with Wood's Hole, and is thus in touch with the entire country.

Current for operating this plant is obtained from a storage battery which is charged when necessary by means of a generator driven by a gasoline engine. The transmitter is of the spark-gap type of 2 kw. capacity, and is equipped for operating on either a quenched spark gap or a rotary synchronous spark gap. The frequency of the radio motor generator set is 500 cycles, with a sparking rate of 1,000 per second. The current in the antennae circuit for 2 kw. input is 15 amperes. The receiver is adapted for either damped or undamped waves over a range of wave lengths of from 300 to 3,000 meters.

The radio call for this station is WSC. Land line charges will be computed from Wood's Hole.

DUMPING BODY FOR TRUCK

The Karry-Lode Truck Company, of Long Island, City of New York, are now manufacturing an all-steel dumping body for their electric trucks. These have a capacity of 40 cubic feet, dump over the end of the truck, and are especially adapted for coal handling.

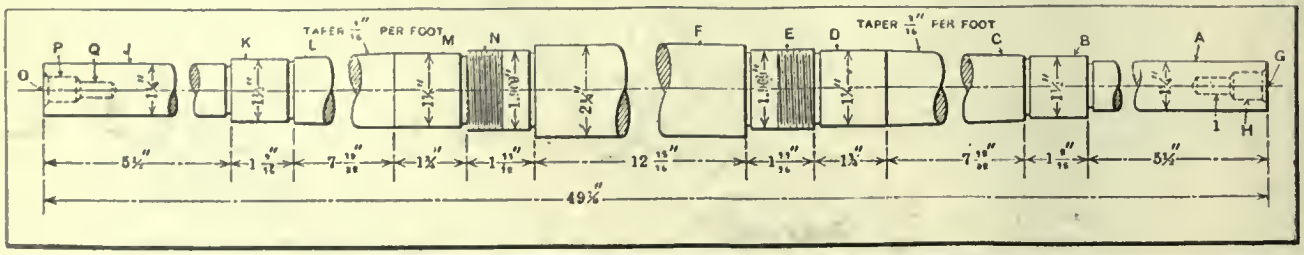

FIG. 13—A LONG STEEL SPINDLE PRODUCED FROM BAR STOCK IN TWO CHUCKINGS.

Portable Boats of Early Railroad Practice

Did You Know That the Transportation of freight and passengers Between Philadelphia and Pittsburgh Was Successfully Conducted in CANAL BOATS? —It Was—But Many Years Ago.

By J. SNOWDEN BELL

IT WILL be a matter of surprise, not merely to the general reader, but as well to most persons familiar with the operation of railroads, to know that many years ago the transportation of freight and passengers between the cities of Philadelphia and Pittsburgh was largely and successfully conducted in canal boats, which traversed the entire distance between these terminals, partly by railroad and partly by canal. There are but few persons now living who, like the writer, have seen these boats in service, and the data as to their origin and development, and their railroad transportation equipment, are so meagre and so scattered that a record of it, while merely a matter of history, may be found also to be of sufficient interest to warrant its presentation.

What was known as the main line of the Public Works of the State of Pennsylvania, extending from Philadelphia to Pittsburgh, and aggregating 394.6 miles, was constructed by the state and completed in March, 1834. It was for a number of years—that is, until June, 1857, when it was sold to the Pennslyvania Railroad Company—operated by the state, under the control of a board known as the Canal Commissioners. It comprised a line of double track railroad from Philadelphia to Columbia, 81.6 miles; a canal from Columbia to Holidaysburg, 172 miles; the Allegheny Portage Railroad, crossing the Allegheny Mountains and extending from Hollidaysburg to Johnstown, 36.6 miles, and a canal from Johnstown to Pittsburgh, 104 miles. Horses were the first motive power on both these lines of railroad, but were soon superseded by locomotives, and mules were always used for haulage on the canals. At noted in Wood's "Practical Treatise on Railroads," 2nd edition, 1832: "This railroad is therefore the first which was undertaken in any part of the world by a government."

The boats used in this system of combined land and water transportation, which were generally termed "portable" boats, will be first considered, and be followed by general notes of the equipment by which, in their earlier service, they were carried over the railroad sections of the route.

The Portable Boats

The transfer of boats from one level of a canal to another, upon carriages running on inclined planes, instead of floating them through locks, of course involved, broadly speaking, their movement both on land and in water. This was a well known practice long prior to the operation of the Pennsylvania public works system, and is even said to have been practiced by the ancients, who did not appear to have known of canal locks. An illustration appears in Stevenson's "Sketch of Civil Engineering in North America," 1838, of a boat and "boat car" used on the Morris Canal of New Jersey, which the author states was "the only canal in America in which the boats are moved from different levels by means of inclined planes instead of locks." This prior practice, however, has obviously no bearing derogatory to the merit and novelty of the Pennsylvania portable boats.

The initial step in the transportation of boats over the railroad tracks of the Pennsylvania public works—which, however, was not on a commercial scale—or by the use of sectional boats, is recorded in Day's "Historical Collections of the State of Pennsylvania," Philadelphia, 1843, as quoted from a prior publication, which is not named, as follows:

"In October, 1834, this portage (the Allegheny Portage Railroad), was actually the means of connecting the waters of Eastern Pennsylvania with those of Mississippi; and as the circumstance is peculiarly interesting we here place it on record. Jesse Chrisman, from the Lackawanna, a tributary of the north branch of the Susquehanna, loaded his boat, named "Hit or Miss," with his wife, children, beds and family accommodations, with pigeons and other livestock, and started for Illinois. At Hollidaysburg, where he expected to sell his boat, it was suggested by John Dougherty, of the Reliance Transportation Line, that the whole concern could be safely hoisted over the mountain and set afloat again in the canal. Mr. Dougherty prepared a railroad car calculated to bear

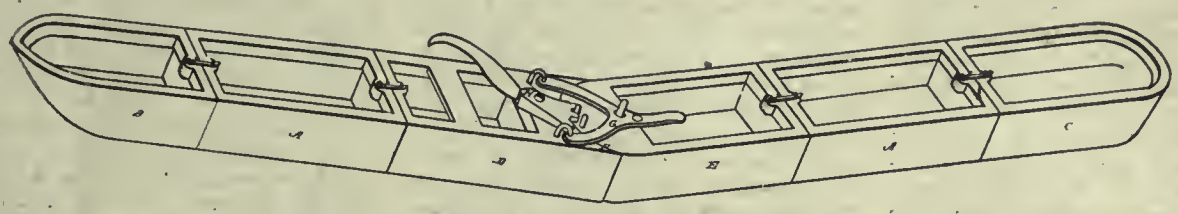

FIG. 1—A REDUUCED REPRODUCTION OF THE ELGAR PATENT CANAL BOAT.

A SECTIONAL BOAT ASCENDING ONE OF THE INCLINED PLANES ON THE ALLEGHENY PORTAGE RAILROAD.

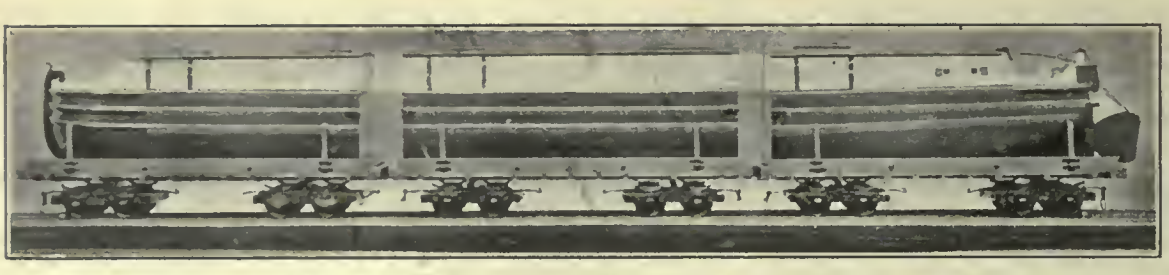

FIG. 2—THE SECTIONAL BOAT PATHFINDER REFERRED REFERRED TO IN TEXT.

the novel burden. The boat was taken from its proper element and placed on wheels, and under the superintendence of Major C. Williams (who, be it remembered, was the first man who ran a boat over the Allegheny Mountains) the boat and cargo at noon on the same day began their progress over the rugged Allegheny. All this was done without disturbing the family arrangements of cooking, sleeping, etc. They rested at night on the top of the mountain, like Noah's Ark on Ararat, and descended next morning into the valley of the Mississippi, and sailed for St. Louis." The author of the "Historical Collections," referring to the conditions of operation when he wrote, adds:

"The trip of a boat over the mountain is now no novel sight, except that instead of going over whole, they are so constructed as to be separated into three or four parts on reaching the railroad. After thus mounting the cars piecemeal, with their loads of emigrants, baggage and freight on board, they wend their way over the mountains, and resuming their proper element at Johnstown, they unite their parts again and glide on to the waters of the great West."

The earliest record of the idea of constructing a canal boat in separate sections for transportation over a portage between two lines of canal, appears in a report on a survey of the Juniata route, made by Canvass White, a civil engineer, to the Canal Commissioners of Pennsylvania, which is printed on page 83 et seq. of the commissioner's report, dated February 7th, 1827. In this report, Mr. White says:

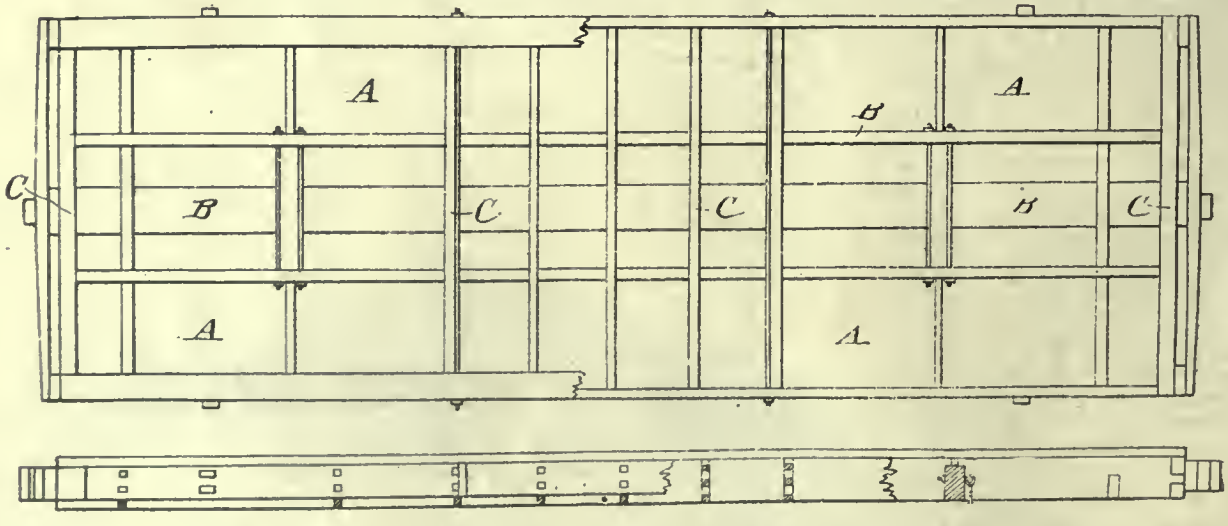
"I made a partial examination of the country over which the railway must pass, and from the general appearance I think the ground is favorably situated, considering the formidable barrier interposed between the eastern and western wtaers. A good turnpike road would probably answer all the purposes of transportation for several years, and a part of the bed could be occupied by the railway whenever the business should require its construction. I would suggest the idea of making the canal boats in three or four pieces, to be divided transversely, and transported over the portage without changing the cargo."

The credit of the invention of means for operating on a commercial scale, transportation of freight and passengers, without unloading and reloading or transferring, over a route comprising both canals and railroads, is due to John Elgar, a civil engineer of Baltimore, Md. After having devised and patented other appliances relating to railroads, a patent of the United States was granted to him on November 7th, 1835, for what he designated as "certain improvements in the art of, and in the apparatus for the conveyance or transportation of goods, on a line where canals and railroads form alternate links in the chain of communication, as for example, on the great Pennsylvania line from Philadelphia to Pittsburgh."

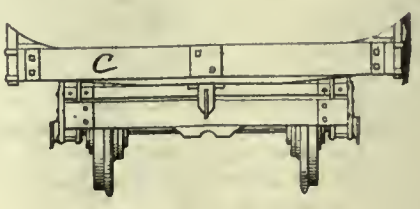
While this patent is later by about thirteen months than the date when the small boat "Hit or Miss" was carried over the Allegheny Portage Railroad, as before noted, and while that railroad transfer from one canal to another may, perhaps, have suggested Elgar's invention, that invention is none the less meritorious, by reason of its inauguration of a commercially valuable practice on an extended scale.

Fig. 1, which is a reduced reproduction of the drawing of the Elgar patent, is apparently the earliest representation of a sectional canal boat anywhere recorded, and the principle of the Elgar invention, upon which the subsequent practice on the main line of the Pennsylvania public works was based, is fully and clearly stated in the specification of the patent, as follows:

"The object which I have in view, in the first instance, is to prevent the necessity of removing the goods from the vehicle within which they are first loaded by constructing cases which serve on railroads as car bodies, and on canals as boats. This I effect by making such vehicles, or car bodies, of sheet iron, in the manner of iron tanks, riveting them up watertight in the same way. The dimensions of these bodies must be determined by that of the canal locks



FIGS. 3, 4 AND 5—A PLAN VIEW OF TRUCK, A SIDE VIEW AND AN END VIEW.



through which they are to pass when used as boats. If, for example, the lock will admit a boat of fourteen feet in width, and eighty in length, the bodies may be made seven feet wide and twenty feet long so that eight bodies, two abreast, and four in length, may pass at the same time. I intend sometimes to make the bodies wholly of sheet iron, but they may be made of that material to a height of about three feet only, with an additional height, say of three feet, made of wood. The bodies, when made of this length, are to be carried upon eight-wheeled cars. If four-wheeled cars are preferred the bodies must be made of a length suitable thereto, and a greater number of them will then, of course, be connected together when in the water.

"As these bodies are, by their combination, to form canal boats, the requisite number of them are to be so formed at one end as to constitute a well-shaped bow, and the same number are to be so shaped as to constitute a stern; the other ends are to be made square so that when connected by proper fastenings they will be in one continuous inflexible line, to the length of the lock through which they are to pass."

On February 24, 1843, patent No. 2973 was granted to John Dougherty, of Hollidaysburg, Pa., who was doubtless the constructor of the car on which the "Hit or Miss" was carried over the Allegheny Portage Railroad, in October, 1834, as before noted. The specification states the invention to be "certain improvements in the apparatus for the transportation of goods on canals and railroads; said improvements consisting in a more perfectly carrying out of the method of transportation for which Letters Patent of the United States were granted to John Elgar, dated on the 7th day of November, 1835, and of which I am the assignee for the State of Pennsylvania."

Fig. 8 of the Dougherty patent is stated in the specification to be a side view of a four-section boat, and Fig. 9, a top view of a double series of sections, bolted or keyed together, but the sheet containing these views cannot be found in the Patent Office, having unfortunately been lost or accidently destroyed. The general features of the design may, however, be understood from the following exerpt from the specification:

"The boats, or boxes, may be made of sheet metal, or of wood; or their lower portions may be of metal, and their upper of wood; the invention not being in any way dependent upon the kind of material employed. I connect these boats, or boxes, together, when they are used on canals, in such manner as that there shall be two sections in width, and three, or more in length. In this respect my plan of connecting the sections is not the same with that adopted by Mr. John Elgar, who proposed to connect them in a continuous line, and in such manner as that they should possess a certain degree of flexibilty at the places where they were joined to each other; but when so joined, they have not been found to operate well, as they cannot be kept with their sides and bottoms coincident, but vary laterally, as well as upward and downward, from which cause they are liable to be injured by snags or rocks, and have their motion retarded by the water. A still more frequent difficulty resulting from the original mode of connecting them has arisen from the want of a free passage of the towing lines from end to end of the boat, all of which objections I obviate by attaching to the fore end of each section, which is to have a rear section joined to it, a plate of iron, six or eight inches more or less in width, and of such length as that it shall extend entirely across the under part of the section, from side to side, and sufficiently high on each side to confine the two parts, or sections, in place.

Such plates are to be bent so as to conform to the curvature of the bottom, are to be fastened to one of the segments by bolts, or otherwise, and to project over and form a ledge, say two-thirds more or less of their width, so that the rear section may be received and rest upon it. The sections are then to be firmly secured end to end by loops and keys, or in some analogous mode, until the intended length is obtained, and two such series of sections are to be secured by bolts, bars, or clasps, side by side, and are thus to constitute a combined boat, of the ordinary width of a canal boat, and in length adapted to the locks through which they are to pass."

An extended search has failed to develop any drawing illustrating the structural details of the sectional boats as actually built and operated, and the recollection of the few now living who have seen them is so much impaird by the long lapse of years as not to be fully reliable. Their characteristic features may, however, be sufficiently understood by reference to Fig. 2, which represents

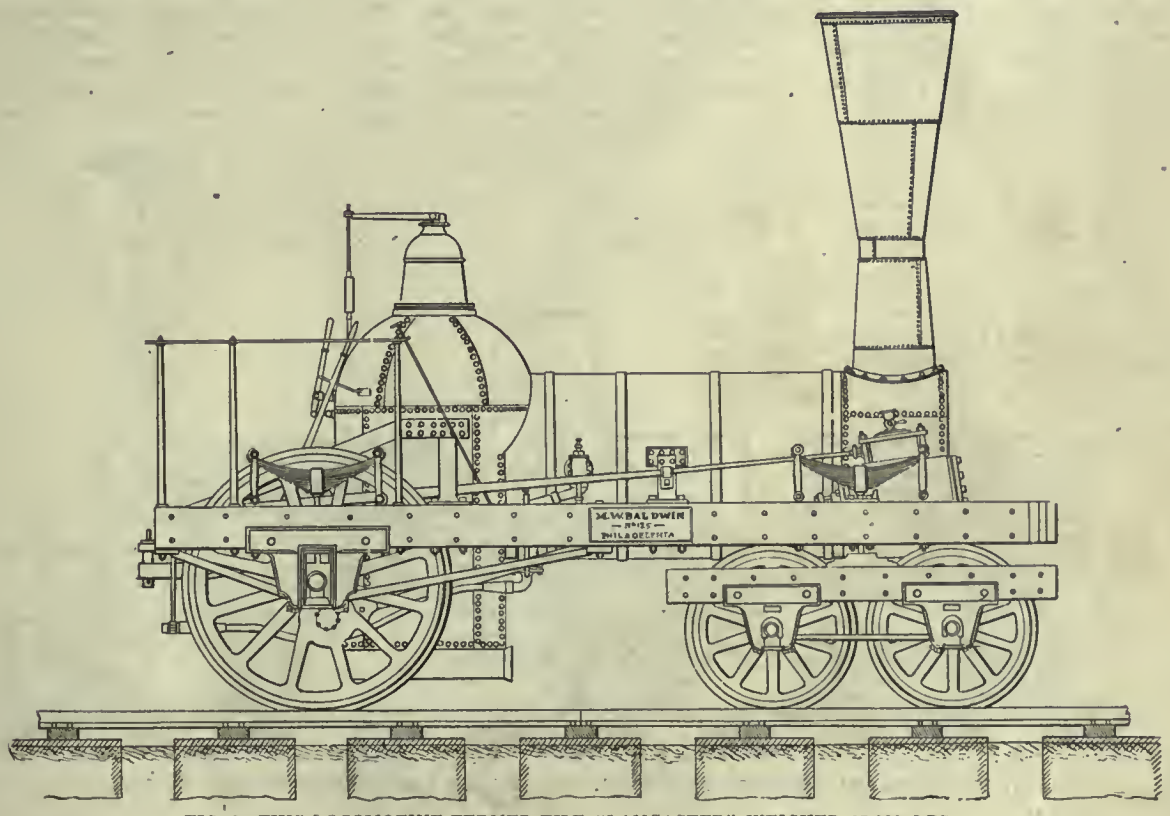


FIG. 6—THIS LOCOMOTIVE TERMED THE "LANCASTER" WEIGHED 17,000 LBS.

the sectional boat "Pathfinder," a model of which formed part of the exhibit of the Pennsylvania Railroad Co., at the Chicago Exposition, in connection with the following description, which is given by Capt. H. A. Walters, of Lewistown, Pa., who, in 1849, started as a driver on the Pennsylvania Canal.

"These (the sectional boats) were 82 feet in length, 13 feet in width, and in depth 12 feet, and were divided into four sections, each 20½ feet long; the boats were round on the bottom and not flat. The sections were fastened together by irons about half way down the side—the iron projected out from the one section into a V-shaped iron on the other section, then a T-iron fitted down through both of these irons and locked them together. One section was placed upon one railroad truck which was a little bit longer than the section—say about 23 to 24 feet, and had four wheels. . . . The trucks were round in the bottom to fit the boat's sections."

Capt. Walters' statement of the width of the boats is manifestly erroneous, as they could not, for the reason hereafter stated, have been in excess of about 7 feet 9 inches in width. This is also indicated in the first illustration, which is reproduced from an illustration in the Philadelphia Commercial Museum, and represents the stern section, and an intermediate section of a boat, loaded on the so-called "trucks," ascending an inclined plane on the Allegheny Portage Railroad, to be delivered to a locomotive at the summit.

The Railroad Hauling Equipment
The Transporting "Trucks"

In transporting the sectional boats over the railroad divisions of the main line of the Public Works of Pennsylvania, each section was loaded upon an eight-wheeled car, known as a "truck," although it was fitted with two four-wheeled trucks, one at each end, and the trucks were coupled up in a train which was hauled over the railroad divisions by a locomotive. On arriving at the canal terminal of a division, the trucks were lowered into the canal, and the sections of the boats were coupled together and hauled through the canal to the next railroad division by horses. The writer has, when a boy, seen sections of these boats, on their trucks, being loaded in a forwarding house or private freight station at Eighth and Market Streets, Philadelphia, from which they were hauled by horses to the Willow Street Railroad, over which the trucks were hauled a few miles by a locomotive to the inclined plane at Belmont, on the Schuylkill River, and thence by a locomotive to the canal at Columbia, Pa.

The only illustration of these flat cars or so-called "trucks," which has been developed, or which it is probable is now in existence, is that which appears in the drawing of the Dougherty Patent before referred to, three of the views of which are here reproduced, as Fig. 3, a plan view of the car body; Fig. 4, a side view, and Fig. 5, an end view. The four-wheeled trucks, not involving any departure from the ordinary practice at their date, are not here shown.

The description of the car, given in the specification of the patent, is as follows:

"In constructing the cradle it is necessary to limit its width to about 8 feet 9 inches; the passing along the road forbidding that this width should be exceeded; it is necessary, also, that the cars should be capable of running upon curves of fifty or sixty feet radius. The truck wheels which I use are about 2 feet 9 inches in diameter, and instead of being kept to the level of the upper sides of the side pieces of the truck frame, as formerly, they are allowed to rise about a foot above them."

The drawing of the patent does not show side stakes, or any other means for holding the boat section in position on the cradle, and if the stakes were used as would appear to be the case, the width of the boat section would probably not be greater than about 7 feet 9 inches in view of the limitation of clearance before mentioned.

The specification further says that: "The longitudinal timber, B, B, may in this case be a foot in depth, and the width of the space, A, A, must be such as, but need not be greater than will admit of the trucks adapting themselves to the curves of 50 or 60 feet radius, as above named. The trucks work on centre bolts, a, a, as usual. The cross timbers, C, C, of the cradle, are on their upper sides, adapted to the form of the bottom of the boat."

The Early Locomotive Power

The Canal Commissioners, under whose control, as before stated, the connected system of railroads and canals over which the sectional boats were run was operated, were authorized by an Act of the Pennsylvania Legislature, approved April 15, 1834, to use locomotive engines as motive power, which theretofore had been horses. In pursuance of this authorization they ordered a number of locomotives from the works of M. W. Baldwin, of Philadelphia, the first of which, the "Lancaster," was put in service on the Philadelphia & Columbia R. R., June 28, 1834, and the second, the "Columbia," September 10, 1834.

The "Lancaster," which is shown in Fig. 6, weighed 17,000 pounds, and had cylinders 9 by 16, and driving wheels 54 inches in diameter. The "Columbia" was of the same weight and dimensions. It is shown by the records that the

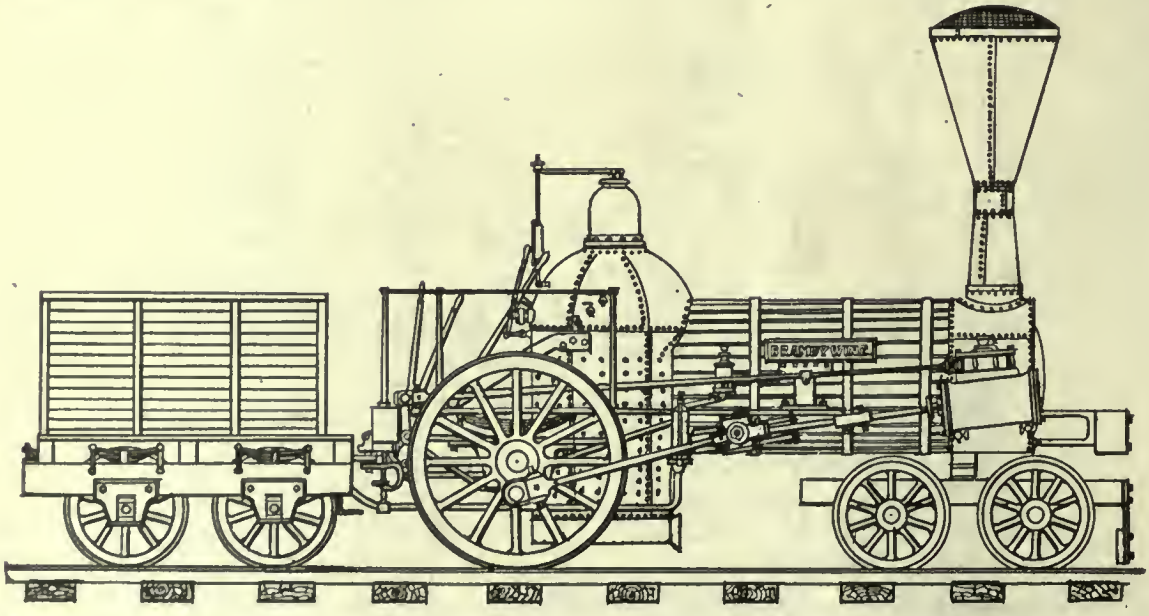

FIG. 7—THE BRANDYWINE. THIS STYLE HAS OUTSIDE CONNECTIONS INSTEAD OF THE HALF CRANK DRIVING AXLE

"Lancaster" hauled a train of nineteen burden cars over the heaviest grades between Philadelphia and Columbia, which was characterized at that time by the officers of the road as an "unprecedented performance." The weight of these locomotives was in excess of that which was estimated by the Canal Commissioners to be within the capacity of the rails of the Philadelphia & Columbia Railroad, as, in their report of December 7, 1833, they say: "The Wiggan (English) rail, weighing forty-one and a fourth pounds per yard, has been adopted for both tracks of the sixty miles now in progress. It is calculated for carrying locomotive engines weighing six tons." The weight of the Baldwin locomotives was not, however, found to be objectionable, and the reports of their performance were, in all particulars, satisfactory.

In his report to the board of Canal Commissioners of November 7, 1834, Mr. Edward F. Gay, principal engineer, referring to the engines "Lancaster" and "Columbia," says:

"Indeed, these engines are justly considered superior and beautiful specimens of mechanism, and reflect great credit on the ingenious mechanic (M. W. Baldwin, Esq., of Philadelphia), who constructed them. They are each supported on six wheels, which is found to be the only arrangement that will enable a locomotive engine to overcome the severe curves connected with the high grades upon this road without injury to the engine or railway."

In the same report these engines are further referred to as follows:

"As all the engines preparing for the road are designed to be of the same class, the following statement of the capacity of the 'Lancaster' may be applied to the others. Weight of engine, 8 tons; capable of drawing 36 tons, exclusive of cars—say 56 tons gross. Amount taken at each load limited to 30 tons, or about 48 tons gross. Running time between the inclined planes (77 miles) with the above load, 8 hours, including stoppages.

Expenses of the Trip

20 bushels coke at 20c	$4.00
1½ cords wood at $4	6.00
Engineer and attendants	4.00
Oil	.60
Total	$14.60"

Eight more locomotives, all of the same general design as the "Lancaster" and "Columbia," were built by Mr. Baldwin for the State up to the close of the year 1835, these being the "Philadelphia," November 26, 1834; "Pennsylvania," January 3, 1835; "Delaware," February 7, 1835; "Susquehanna," March 12, 1835; "Schuylkill," April 1, 1835; "Kentucky," July 14, 1835; "Juniatta," September 5, 1835; and "Brandywine," October 21, 1835.

As shown in Fig. 7, the "Brandywine" differed from the first engines in having outside connections instead of the "half crank" driving axle, and an iron frame instead of a wooden one. The report of Mr. Gay, the principal engineer, rendered November 7, 1834, includes an estimate for "Eighteen locomotive engines and tenders complete, at $6,300 each, $113,400," and in his report of October 30, 1835, which covers all the ten before noted Baldwin locomotives, he says:

"The engines upon this road have generally performed their trips with great regularity; and it affords me pleasure to add that the American engines, delivered within the present year, are capable of doing more work than was estimated in my last report; the most of them, in their ordinary trips, draw a gross load of 75 tons. The engine 'Schuylkill' has drawn over the road a gross load of 100 tons, and several others have drawn, over the highest grade, from 80 to 90 tons gross. When the curves and grades upon the road are taken into consideration, it is believed that the performance of these engines will be found equal to any in America."

The second locomotive that was built by Mr. Baldwin, the "E. L. Miller," which was the immediate predecessor of the "Lancaster," was equipped with a form of traction increaser by which a portion of the weight of the tender could be transferred to the driving wheels of the locomotive, thereby increasing their tractive power. This device was brought out by E. L. Miller, president of the South Carolina Railroad, for which road the engine bearing his name was constructed, and a patent for it was granted to him, June 19, 1834. As the Miller device was applied on locomotives built for the Canal Commissioners, a description of it may be found of interest in this connection.

Fig. 8 is reproduced from the drawing of the Miller patent, the specification of which specifies the invention as consisting in "using the tender, or car, next to the engine, for the purpose of adding weight to the driving wheels of the engine at such times only as a greater adhesion is required than the weight would give, which it would be practicable to carry as a fixed weight on those wheels without injury to the road."

The specification describes the construction and manner of operation of the traction increaser in the following terms: "The mode which I have used and found to answer perfectly in practice, is simply to connect the car, or tender, next the engine, to the engine by a strong iron bar, or lever, one end of which is bolted to the under side of a cross timber in the frame of the car or tender, a little back of the centre and which lever extends under the frame of the tender to the end of the frame of the engine and into the iron which together with the drawing bolt, secures it to the engine.

"Transversely to this lever, I attach to the end of the tender next the engine, two levers, so that their fulcra shall be six or eight inches on each side of the main lever, or drawing bar. These levers have a jaw, or pivot, five or six inches in length, directly over the main lever, and should be about 4½ feet in length.

"When the increased adhesion is wanted, the engineer has only to place his foot upon the ends of these levers and press them into a hook, or groove, for that purpose, on the corner post of the tender; and a portion of the weight of the car, or tender, next the engine, is thus thrown upon the driving wheels of the engine; and when the increased adhesion is no longer wanted, this weight is detached by simply loosening the ends of the levers."

In his report of October 30, 1835, Mr.

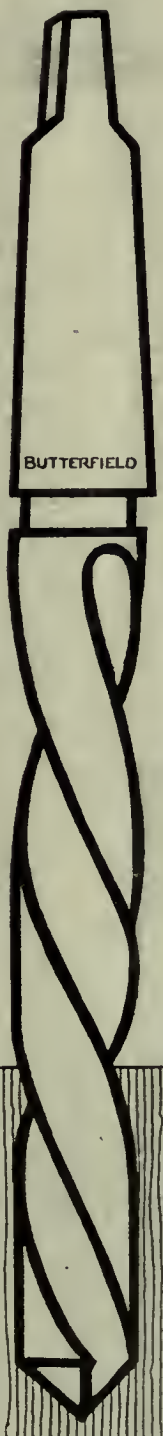
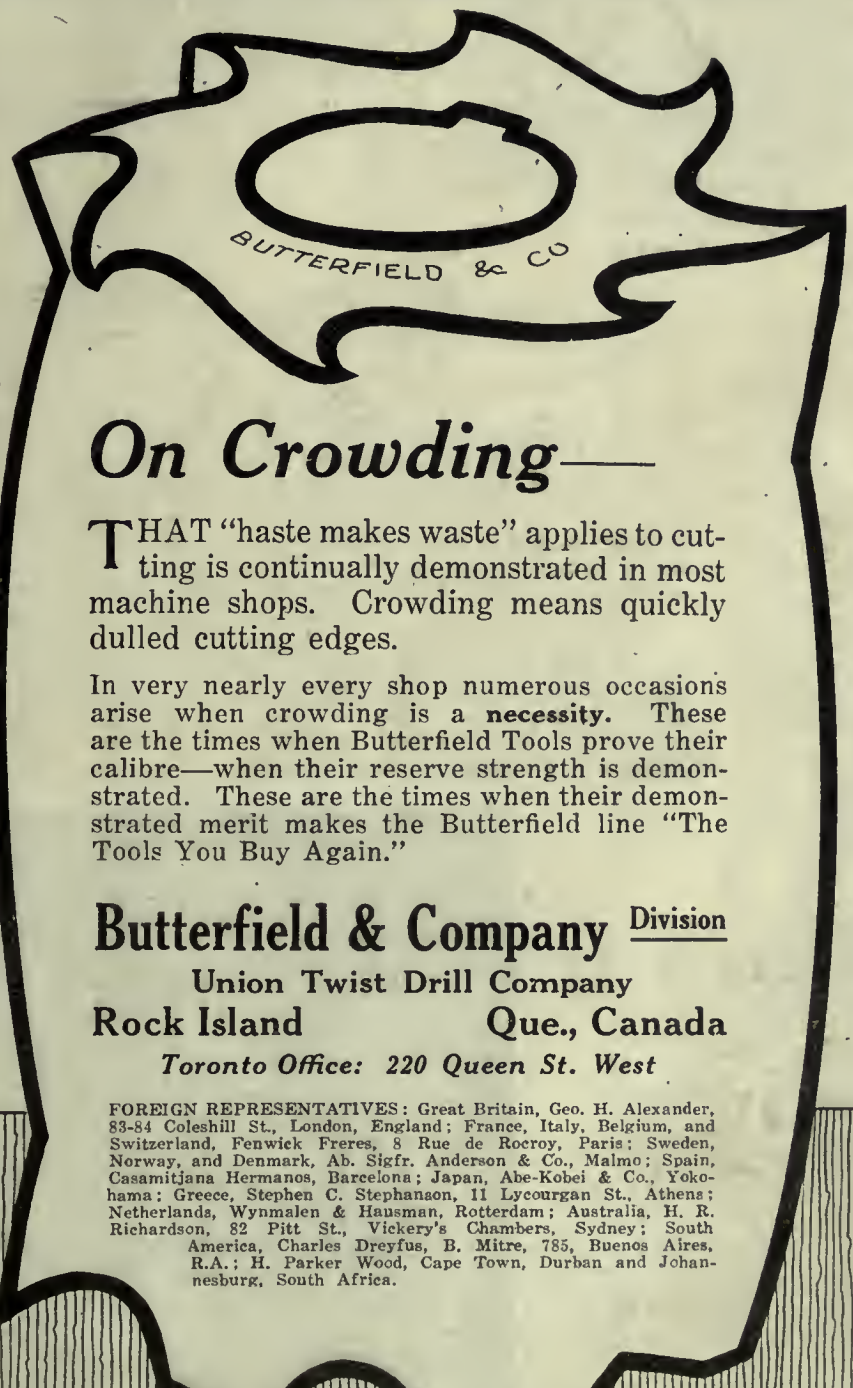
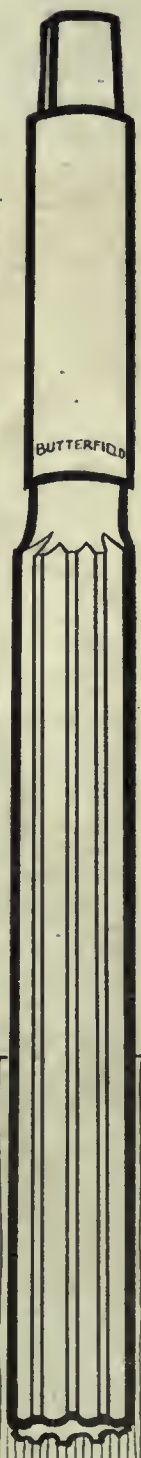
FIELD







On Crowding——

THAT "haste makes waste" applies to cutting is continually demonstrated in most machine shops. Crowding means quickly dulled cutting edges.

In very nearly every shop numerous occasions arise when crowding is a **necessity.** These are the times when Butterfield Tools prove their calibre—when their reserve strength is demonstrated. These are the times when their demonstrated merit makes the Butterfield line "The Tools You Buy Again."

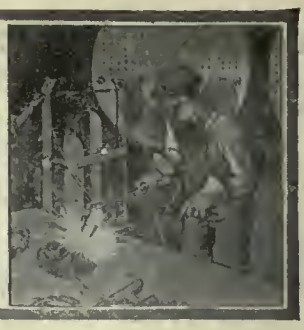
WELDING AND CUTTING



Facts Regarding the Oxy-Acetylene Process

The Examples of Work Shown with Data Pertaining Thereto, Have Been Compiled by Author from Information Applied by L'Air Liquide Society

By J. H. MOORE

THE fundamental principles of oxy-acetylene welding are easily understood, and when one has already a rudimentary knowledge of the physical and chemical properties of metals, it does not take long to become proficient in the work after some experience has been acquired in the use of the necessary apparatus. The two gases, oxygen and acetylene, are well known and need no explanation. Oxygen is compressed and supplied in steel cylinders. Acetylene is supplied in dissolved state in cylinders first filled with a porous material soaked with acetone, which removes any risk of explosion, or may be obtained from a suitable generator.

Acetylene, when burnt in equal proportions with oxygen produces a neutral flame (that is, neither oxidizing nor carbonizing), of an estimated temperature of over 7,000 degrees Fahrenheit. All metals under the direct influence of this intensely hot flame melt rapidly. Suitable additional metal is added to fill up the groove between the two pieces and results when allowed to cool in a perfectly homogeneous joint of practically equal strength to the metal adjacent. The gases pass through regulators specially designed to reduce the pressure of gas emanating from the cylinders to a suitable working pressure, afterwards passing through special flexible tubing into the body of the blowpipe in which they mix in predetermined proportions.

Perfect results, however, can only be obtained by the use of perfect apparatus. In selecting apparatus it is essential that only the best is purchased. The question of cost therefore should not be the only consideration to enter into when the question of purchase is considered. So called "cheap" (or inferior) apparatus is not only detrimental to good work but represents an element of risk to the operator, and a few dollars presumably saved on the first cost would be more than lost the first time of using it; besides being wasteful in the use of gases, with the likelihood of discredit to the worker or his employer arising in the future.

On the other hand, when perfect apparatus is used the results obtainable are only limited to the skill of the operator. The cutting of wrought iron and steel is based on the well-known fact that when iron is heated to a high temperature in the presence of pure oxygen it rapidly burns, and forms oxide of iron, which melts at a lower temperature than the metal itself. The apparatus for oxy-acetylene cutting is similar to that used for oxy-acetylene welding except that the blowpipe or cutting torch is so constructed that a stream of pure oxygen acts on the heated metal and oxidizes it. The resulting oxide liquefies almost simultaneously and is blown away by the action of the blowpipe. This process of oxidation and liquefaction is rapidly repeated until the metal is severed by a clean and narrow cut, either through its entire depth or such part of it as may be required.

Cutting by Oxy-Acetylene Process

Cutting all thicknesses of wrought iron and steel by the oxy-acetylene process has now become a common method. Not only is the cutting by this process rapid, but it is also very much cheaper in consequence of the enormous saving of time and labor. It is practically as easy for the operator to cut a circle or any other design as it is for him to cut straight across, which is all that can be done, of course, by sawing.

There is hardly any limit to the thickness of steel, etc., which can be cut by this process if proper equipment is used, and the many machines that are on the market designed for the cutting of heavy thicknesses of steel, working more or less automatically, and the success they have attained, bear testimony to the essentialness of such a process.

For ordinary purposes, where the metal

FIG. 1—A GOOD EXAMPLE OF HOW THIS STYLE OF WELDING CAN BE USED TO ADVANTAGE.

FIG. 2—THIS ENGINE CYLINDER WAS REPAIRED IN 48 HOURS.

FIG. 3—A NAIL MACHINE THAT ANSWERED TO THE ROLL CALL IN 48 AFTER DISABLEMENT.

is only a few inches in thickness the work is very easy and requires no mechanical assistance; in fact, a man can become an expert operator after very little training.

The question is sometimes raised as to whether cutting by the oxy-acetylene flame has any harmful effect on the material, and the answer is emphatically, No! Mr. P. F. Willis, who is an impartial authority on the subject, makes the following allusion to this subject in his book "Oxy-Acetylene Welding and Cutting." "Is there any detrimental change in material when cut with oxygen?"

No. On high carbon steels there is a slight softening of the metal for a distance of about ⅜ inch from the cut, due to the annealing effect of the heat. Numerous tests have been made and all bear out the above assertion. The results of one such test may prove interesting. A steel plate ¾-inch thick and 14¾-inch long was used.

	Test No. 1	Test No. 2
	Original Stock Before Cut	After Cut
Tensile	47,620 lbs.	50,110 lbs.
Elastic Limit	31,640 lbs.	29,930 lbs.
Elongation	33%	33%
Reduction of Area	35%	42%

It is an advantage, when cutting, to have the blowpipe perfectly steady, with the tip at a distance of about ⅛-inch from the surface of the metal, for ordinary thicknesses.

Cutting discs out of steel plate is a comparatively simple process, and requires very little skill on the part of the operator. Some concerns supply a circular cutting guide which enables the operator to cut a perfect circle of almost any diameter with no more effort than is required to control the blowpipe. Cutting heads off rivets when repairing boiler and structural steel without injury to the plate, is also a particular advantage of this process. By cutting off the head, it only requires a tap of the hammer to knock out the rivet. In certain instances, this is the only practical method of taking out rivets, especially in places where they are inaccessible to a hammer and cold set.

For cutting out discs and intricate designs in iron and steel this method is especially valuable. Cutting up scrap and dismantling steel structural work is also an important field for the oxy-acetylene process, and is the solution to many problems of a similar nature, such as clearing up wreckage after a fire, train disasters, etc.

Its Efficiency and Economy

The time was, and not long ago, that when an important part of machinery broke there was no alternative but to replace it by a new part if procurable, or patch it up by some crude method which usually could be depended upon to give but temporary service only. Sooner or later the time would come when a new part had to be obtained or the machine discarded and condemned

FIG. 4—A FEW HOURS MADE THIS FACE PLATE AS GOOD AS NEW.

FIG. 5—A FEW HOURS WAS ALL THAT WAS NECESSARY TO PUT THIS GEAR IN WORKING CONDITION.

FIG. 6—THE CYLINDER BEFORE WELDING.

FIG. 7—HOW IT LOOKED AFTER BEING WELDED.

altogether, and replaced by a new one.

Probably at that time, when such machinery was comparatively cheap to buy, this might have in the end been considered economy as one could naturally get more service from a new machine than an old one more or less out of order, but with the advent of the oxy-acetylene process of welding these methods came to be looked upon as unnecessarily wasteful, and at the present time would be regarded as positively inefficient.

With the speeding up of all industries directly or indirectly concerned in the production of war material, machinery and equipment became taxed to the utmost so that when an important part or a casting became broken oxy-acetylene welding was looked upon as a highly practical and efficient method of restoring it to use again—not only from the standpoint of economy, but because it might be welded in a few hours and made practically equal to new, whereas to procure a new part would take very often several weeks, and in the case of foreign made machinery, would be altogether unobtainable.

The more the price of machinery has risen and the greater the scarcity of metal of all kinds, the more valuable the oxy-acetylene process has come to be regarded until it is now looked upon as an indispensable necessity in all industries, and for all purposes where the joining of metals is involved. There is practically no inherent weakness in the welded joint when the work is properly performed, especially on cast iron and steel. The tensile strength of a weld on cast iron is equal to or greater than the metal itself. In the case of steel, the welded part is about 90 per cent. to 95 per cent. of the strength of the metal.

Even on brass and copper, upon which welding is not attempted as often as it should be, the results are better than can be obtained by riveting or any other method of joining which are consequently rapidly being superseded by welding.

It will therefore be seen that this process holds out many advantages, especially to the manufacturer of metal furniture and utensils, cylinders, drums, containers, etc., where a joint of neat appearance and absolutely leak-proof is necessary; and where the article has to be subjected to great pressure. After smoothing off the welded part it is quite impossible to detect the joint so that it is for all practical purposes seamless.

In certain cases such as the manufacture of bakers' dough vats, where it is necessary that the article, when in use, has to be absolutely clean in every respect, the fact that there are no seams or apertures which would make it difficult for the receptacle to be kept quite clean and free from deleterious matter, the practically seamless article made by oxy-acetylene welding has much to commend it even when strength is not of great importance; furthermore, more often than not it can be made cheaper by this than any other method.

There is hardly an industry of any kind but has its own use for this process in some way, either for repairing or manufacturing, or for some other purpose incidental to either of these two. To recount them all would be quite impossible, but the following are a few of the uses to which it is most comomnly applied, and will be sufficient to give a general idea as to the many other similar uses to which it could be profitably adapted.

Railroads are saving thousands of dollars yearly and keeping their rolling stock in constant service by welding broken locomotive cylinders, drive wheels, welding cracks in fire boxes,

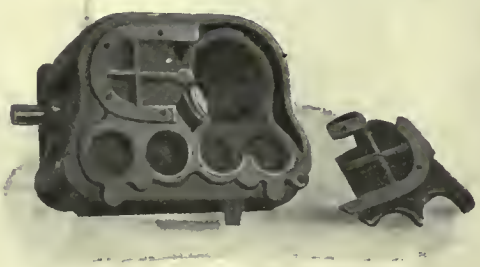


FIG. 8—AUTOMOBILE CYLINDER BEFORE WELDING.

mud rings, flues in flue sheets to eliminate leakage, broken forgings of all kinds, cracked or defective steel castings, broken flanges on cylinders, frames, crossheads, quadrants, reverse levers, etc., etc.

Shipyards, by repairing broken cylinders, broken propeller blades, damaged engine parts, boilers, davits, stern posts, cutting manholes and portholes in steel plates, cutting up wreckage, etc. Steel and brass foundries by building up defective castings, filling up blowholes, welding cracks and otherwise saving parts which, by being somewhat defective, would be useless for the purpose required; cutting off steel gates, risers and runners, welding cracks in bronze bells, etc. Pulp and paper mills by welding broken gears, machinery parts, paper cores, etc.

Machine shops are reclaiming parts that have flaws in them, either by accident or other fault, and saving the amount of work spent on them; welding broken machinery parts, etc. Big savings are also being effected in various industries by welding high speed steel to low carbon shanks and using up every part of a tool after it has become too small for ordinary use. This admits of the whole of the high speed steel being utilized, which, owing to its high cost, is an important consideration.

Garages also have many and important uses for this process for welding broken crank cases, cylinders and water jackets, lengthening and straightening chassis, welding broken crank shafts, gear shift rods, fenders, gasoline tanks, radiators and many other broken or damaged parts but which it would take too long to enumerate. So manifold and varied are the uses for the process that it has almost come to be regarded as an axiom that, whenever two pieces of metal are to be joined, the best and most economical method is to weld them.

Believing readers will be interested in actual illustrations of work performed we show throughout this article some examples of good judgment in welding. The first of these, Fig. 1, shows a part of a handkerchief-making machine, which, together with about 100 small parts, was broken in transit. As this machine was made in France, an

FIG. 9—THE CYLINDER AFTER WELDING.

attempt to secure a new casting would have caused untold delay. The dimensions of all the slots shown were in millimetres, which made it still harder to even contemplate making a new pattern. The expense of replacing, not to speak of delay, would have been considerable.

The problem, however, was easily solved. The casting was welded by the oxy-acetylene method, and restored to use again within a few hours. It was practically equal to new, and the cost of

You can do so very easily, at the same time increase your knowledge and powers of perception.

The scale is 6 in. long and is made from finest quality steel. One side is marked in 32nds, the other side in 64ths. A table of decimal equivalents is also stamped on one side, and a table of tap drill sizes on the reverse side. This scale is well worth securing.

Rules of the Contest

SO many favorable comments have been made regarding our "Interesting facts to be found in this week's advertising section," that from now on a prize will be given each week to the reader sending in the greatest amount of correct answers to this section of our journal.

Each week a list of similar nature to that below will be published. It will be up to the reader to peruse the list, then turn to the advertising pages and find the firms we refer to. These puzzling references are interesting to follow, and will quicken your powers of perception. It costs nothing, you get acquainted with the different lines, and have an opportunity to win a prize worth while.

Something that keeps square without a policeman watching it.
A product that is said to use less steam in the long run than the steam engine.
How to keep heat under accurate control.
Something that is said to positively lower industrial costs.
How to obtain various kinds of lines.
A demand that is said to increase daily.
A machine that can be rigged up in three different ways.
That it takes 25,000 of one article to produce one of another in some cases.
That two men can do the work of eight, providing they work with the correct material.
Something that can be worn long hours at a stretch without discomfort.
That benefits are derived from correct distribution of metal in machine design.
That it is possible to bring joy to a machinist's heart.
A talk on engines that is helpful and interesting.
That you can secure a machine capable of handling various jobs without a change of tools.
That faith in Canada and its industries can make a firm expand.
That all the diamonds are not used to decorate ladies' fingers.
Sixteen important helps to Canada that are all members of an equally important organization.
What to do if you have a pumping problem.
How to get out from under the tax burden.
An element that claims to be a cousin to radium.
How to assure a future of steady, dependable output.

DEVELOPMENTS IN SHOP EQUIPMENT

UNIVERSAL GRINDER

The Jones & Shipman, Ltd., Leicester, England, have placed on the Canadian market the universal grinder shown in the illustration. It is known as their model 273 and is used for both internal and cylindrical grinding. There are several features of interest which are herein described.

The columns are high grade castings of rectangular section designed to afford maximum rigidity. The wide spread bases have three-point bearing contacts proportioned to eliminate vibration. The body carries the reducing gear and change feed for the sliding table, together with the clutches for the automatic change feed. The automatic reverse is enclosed in a box on the front. The table is pivoted on a secondary slide provided with a hardened central spigot, and is adjustable for taper grinding by means of a hand-wheel and screw. The setting is registered on a scale reading the taper per foot and the angle in degrees. A T-slot is planed the full length of the table to hold any special work, in addition to the angular slot carrying the work-head and tailstock; the work-heads are pulled up by this angular slot against the master straight-edge in front of the table, ensuring perfect alignment.

The table slide is always covered and guards are provided to exclude grit and water. As it always travels over the full length of the slide-ways of the bed, such slight wear as ultimately occurs is evenly distributed and accuracy is maintained over the whole length. The traverse is automatic with eight variations of speed, lowest 15 inch, highest 109 inch per minute. The wheel head is of massive construction, ensuring a perfectly steady running wheel. The wheel spindle—of special case-hardened steel—is finished to a high degree of accuracy. The bearings are of phosphor bronze, lubricated with wick feed, with double ball thrust for taking up all end play, and exceptionally well protected against dust. It is bolted on to the swivel table on the cross slide, and can be securely locked in any position. It also carries an adjustable driving bracket for the drive to the internal spindle. The head carrying the internal spindle is a separate fixture mounted on the same swivel table, and is of suitable dimensions to carry super high-speed spindles. The design throughout is carefully proportioned to eliminate all vibration.

The cross slide carries the wheel-head and also the internal grinding head, and is arranged to swivel in a complete circle enabling either the external or internal wheel to be brought into use without disturbing the work; its movements are fully graduated. The cross feed to the wheel head is automatic and variable, and is rendered very sensitive by an arrangement of counter-weighting the cross slide. It is fitted with accurate and reliable trip mechanism for sizing the work. Automatic sizing of work is attained by setting the adjustable knock-out to the required diameter, and engaging the automatic cross feed, which is instantly stopped when the wheel has advanced the predetermined distance.

The work head is fitted to a graduated swivel base on the table. It carries a double pulley to give fast and slow speeds for a large variety of grinding, and is arranged to carry a face plate or chuck, and may also be locked for dead-centre grinding. The tail stock or back centre is of massive design, lever operated, the compression of the spring being so arranged that not only is it adjustable for light and heavy work, but can be set for any given position, thus preventing the centre from pressing into the work more than the desired amount. Its adjustable spring tension accommodates the expansion of the work when grinding. The water service is incorporated in the machine; the water taken is easily accessible for cleaning purposes. A high grade geared pump forces a heavy volume of coolant through flexible armored hose to the adjustable nozzle attached to the wheel guard, the return being through inclined water ways and strainer to a removable filter tray, thence over a weir to a sump and tank.

Lubrication. A sinple and efficient

GENERAL VIEW OF THE GRINDER.

system throughout enables every working surface (which is not already self-oiling) to be readily supplied with oil with a minimum of trouble. Following are the chief dimensions: Capacity between centres, 12 in. dia., 24 in. long; table traverse, 24 in.; table taper adjustment, 30 deg. included; height of work head centres, 6⅛ in.; working surface of table, 43½ in. by 6 in.; cross traverse of wheel slide, 6½ in.

Number of work speeds, 8; number of wheel speeds, 3; size of disc wheel, 10 in. by 1 or 1½ in.; countershaft driving speed, 500 r.p.m.; horsepower, 4½; floor space, 96 in. by 52 in.

FILTRATION AND STERILIZATION

To the man who is not vitally concerned the matter of machine tool lubrication may not appear of much importance. On the contrary, it is of proven importance, otherwise there would not be the demand for such a large number of different cutting oil liquids and compounds.

It was not so long ago when the ability to increase production by liquids applied to cutting tools was recognized and the initial steps taken along that line. Water was the first liquid tried, used as a stream feed, or provision made so it would be allowed to trickle upon the tool and work. A little experience in this way proved that a mixture of soda and water was more satisfactory all around, as the tendency to rust and corrode was largely overcome.

The evolution of machine shop practice, requiring high speed tools, carried with it efforts for extreme accuracy in machining and the element of increased production. With the speeding up of tools it was readily recognized that in order to keep down operating costs and produce a product of the highest quality, it would be necessary to use a cutting fluid which had not only the cooling properties necessary to absorb excess heat, but lubricating qualities as well, to increase accuracy, decrease the power consumed, and at the same time speed up production.

With the production of a cutting oil which would serve the double purpose came the increased cost and this item must, of necessity, be kept at the lowest possible figure, otherwise the product could not be marketed. It was, therefore, apparent that an equipment which would filter and sterilize the liquid would eliminate the necessity of throwing the used oil away. This method would reduce cutting oil expense and still promote high speed operation.

The S. F. Bowser Company, Limited, oil storage and filtration engineers, Toronto, are out to meet this need and have designed a filtering and sterilizing system which will soon be placed on the market. The illustration gives a good idea of its appearance and construction. These embody the tried and true principles of screening, precipitation, filtration and sterilization, all combined in a commercial and practical manner. This class of filtration is not a venture or experiment, and the company have had systems, essentially the same, in service for several years, which are giving the very best results.

An installation of this nature will naturally increase the life of the cutting tools, decrease power consumption, permit higher operating speed, increase accuracy, give better lubrication and save throwing away oil which has been used. By this conservation a better grade of oil can be used—one which will not foam, rust or corrode the work or tools. While the filtering process, which is automatic, is under way, the oil is also sterilized, thus eliminating obnoxious odors and preventing infection, thereby preserving the health of the employees.

The systems are so designed that they can be adapted to conditions prevailing and arranged to accomplish the work required. From the machines and chip separators the oil, either by gravity or special provision, can be delivered to the filter and sterilizer which automatically removes foreign matter and sterilizes the fluid. After going through a series of compartments, screens, filtering devices, etc., the liquid is delivered to the filter tank, which acts as a temporary storage. From this tank the oil can be returned to the different machines the same as new oil and used again.

NEW THINGS IN MACHINE TOOLS

ADJUSTABLE WRENCH

The Allen-Diffenbaugh Wrench & Tool Co., Baraboo, Wis., have marketed an adjustable wrench which automatically grips a nut when the handle is pulled. It is made in several sizes from drop-forged steel and has jaws that are machined and hardened.

UNIVERSAL CLAMPS

The Burvin Co., Inc., 87 Warren Street, New York, are marketing tools known as the Force universal clamps. These are made by the Black Rock Mfg. Co., Bridgeport, Conn. in several sizes adapted to hold irregular work on milling machine tables.

PLANING MACHINE

The Powell Machine Co., 245 Stafford Street, Worcester, Mass., are marketing a 48-inch x 17 foot belt-driven planing machine of the high-speed type. The feature of this machine is the accelerating drive which overcomes many of the difficulties so far met with in designing planers of the heavy type.

OIL COOLER

The Griscom-Russell Co., 90 West Street, New York, have placed on the market a device known as their multi-whirl cooler. The device is designed for cooling the oil used in the lubrication of turbine bearings and reduction gears, or the quenching oil used in the heat treatment of steel. It is claimed that by means of this device the oil can be maintained at the proper viscosity for efficient results.

STARTER FOR MOTORS

The General Electric Co., Schenectady, N.Y., have issued an automatic starter for use with squirrel cage induction motors driving lineshafts, pumps, compressors, and similar devices. The starter is operated by a push button or by a float switch, pressure governor, or some similar automatic accessory.

These Changing Times

THE business community in Canada can well heed the remarks of many of the best thinkers on this continent who are trying to bring home the fact that there is a real and vital responsibility resting upon it right now in maintaining a substantial activity in operations during the period of price adjustment.

A policy of moderation and sympathy is needed. The forcing of any man or of any company to the wall should be avoided if there is any honorable way out of such a move.

Manufacturers of either raw, semi-finished or finished material should do their utmost to prevent unemployment, and in this they should have the co-operation of every employee.

The man in the shop should recognize that the management has a real problem on its hands now. Financing is not easy—it is hard, especially for firms that have not been in existence long. There are managers and presidents who are drawing hardly anything at all in the way of salaries at present. The business is simply taking it all, and their optimism for the future and their determination to participate in the development of months to come keep these men in a state of suspended, if not actual poverty.

Occasionally one hears a remark to the effect that "the worm has turned, and we—the management—are going to have our turn now. The men in the shop have run this place for the last four years and we are going to let them know now what a pinch feels like." This attitude is not general, but it exists in some places. Its application to shop management now would be the veriest nonsense.

Nursing a grudge is wasted energy—it will not turn out one extra casting in a year—it will not get any better results in the tool room or the machine shop—neither will it make any other department any more capable or efficient.

There should be a reasonable policy to bring about as much employment as possible. Unemployment is not desirable at any time—it strikes too quickly and too surely at the homes, at the wives and children.

The Canadian trade has so far kept its head fairly well in the matter of cancellations. It is highly desirable that this attitude should continue. An avalanche of cancellations, were they allowed, would start a circle of trouble so vicious that one could hardly measure the element of danger it contained.

All things considered, there is a fair volume of business passing in Canada. It is not to be expected that much expansion will take place until prices and values find new working levels.

The business community in Canada is going through these changing conditions successfully.

Common sense, confidence in the future, an honest day's work and a fair amount of actual and honorable sweat will put us across safely and give us a start on an era of development such as we have not witnessed heretofore.

Another Harmless Boiler Explodes

ONCE again has a boiler, used on a farm for the purely agricultural purpose of threshing proved that it is not exempt from the physical laws that govern other steam-containing, or pressure-containing vessels, though it is free from legislation. It proved this elemental fact by the very impressive means of blowing up, fortunately without hurting anybody. The men in the immediate vicinity had a very lucky escape, and those who were further away from the firing line were also fortunate, as some pieces weighing several hundred pounds were reported to have landed several fields away.

It shows surely a lack of consideration, or a sense of the fitness of things, on the part of these boilers to blow up when several successive governments have decided in their wisdom that these boilers cannot blow up, and are perfectly harmless domestic pets. The process of reasoning which decided that because a boiler is on a farm it is going to act differently under given circumstances than a boiler in an industrial establishment is not very clear to the ordinary mortal. Furthermore, the boiler on the farm is supposed to be possessed of sufficient intelligence to enable it to perform its functions without the aid of any skilled help. It is very likely that the real reason of the exemption of boilers on the farm from the Steam Boiler Act was on account of the farmers all possessing votes, and the fact that a farmer suddenly called upon to pay inspection fees, and probably higher wages to skilled help, would have emitted a howl that would have been heard uncomfortably in Queen's Park.

Now that we have a Government composed largely of farmers it is hardly likely that they will pass legislation that will cause them to be under this necessity. We must therefore submit with what degree of patience we can to the spectacle of occasional boiler explosions on farms, with or without loss of life, until someone who is not afraid of adverse votes gets a measure put through that will include farm boilers.

Our own opinion is that if there is any place on earth where a steam boiler should be subject to rigid inspection, it is on a farm, because anyone who has noticed the way many a farmer treats his farming implements can form a fair estimate of the way he will look after such a thing as a steam boiler.

We have pointed out from time to time in these columns the potentiality of danger that lies in any vessel containing a quantity of water under high steam pressure, and the fact that it was of relatively small size did not eliminate the danger. If one were to take the kitchen kettle and carefully seal the spout and tie the lid on after filling it with water, and then place it over the flame of the gas heater or the coal fire, it would probably blow the kitchen to pieces. The smallest boiler is much larger than the biggest kettle. Why should it be exempt?

Machinist Should be Given a Variety of Work

By T. DALY, Works Engineer International Harvester Co., Hamilton.

THE status of the all-around machinist has always been an interesting subject and readers no doubt read with interest the views of R. W. Gifford in our October 7 issue. T. Daly, works engineer for the International Harvester Co., Hamilton, Canada, has his own ideas on this subject, and here they are:

To my mind the all-around machinist is not passing out completely, but I do believe that the modern machine shop methods do not produce the same proportion of all round men as formerly. The tendency of to-day is to develop mechanics who are, more or less, specialists. The volume of modern industry and keener commercial competition have quickened the effort for increased production. Production is influenced by three important factors: the division of labor, the co-operation of labor, and the use of machinery.

Primitive man lived in a state of sturdy independence. He made his own weapons of defence, hewed his own log canoe and ground his own corn. When civilization came and community life developed, men chose definite trades. The blacksmith or armourer made implements and weapons, the carpenter worked in wood, and the mason built in stone. This division of labor was thus a natural outcome of the growth of communities. To my mind the advantages of divided labor are as follows:

1. Increased skill in the workman; as for example, in the tempering of tools by a toolsmith. 2. Saving of time; as in operating a crane, the slinger securing the load and the driver controlling the hoist. 3. The tendency for the workman, when encouraged, to improve the machine or method, if his mind is concentrated on his work. Many improvements have thus originated. 4. Greater efficiency of the workman by being kept to the work he can do best; it would be wasteful, for instance, to keep a good pattern maker working on rough carpentry.

Against this it may be contended that: 1. The worker's pride in his craft is often destroyed by its subdivision into simple and monotonous processes, and he may feel no responsibility for the product as a whole; hence much inferior workmanship. 2. Excessive monotony tends to make the workman a mere machine, and does not develop his intelligence. 3. If his task is changed, his usefulness is often lost. 4. The function of industry being to provide the material means for a good social life, the undue subordination of human beings to any mechanical system should be resisted. By the co-operation of labor the combined action of numbers can accomplish what one man alone cannot do; as in the erection of a steel bridge.

On the use of tools and machinery, all industry is dependent, for the rudest agriculture could not be carried on without a spade, nor traveling at 60 miles an hour on the railway without an engine. During the war the necessity of the times caused a further subdivision of labor. Unskilled help was brought into the munition industry, given a brief training on special machines, thus producing numbers of specialists who are just "machine hands." Had sufficient trained men been available this work would have been more in their hands, but under the circumstances the real machinist had the better class of work, and the making of safer and quicker tools and machines for use by unskilled operators. This influx of unskilled labor into the mechanical field makes the machinist imagine his services to be underrated.

Will It Lower Standard

If asked the question, Will the passing of the all-round machinist lower the standard of his calling? I would say this, that the man who has served an old-time apprenticeship will regretfully nod his head. He recollects how in the old days he used to mark off his own work, do his own simple forging, or chalk on a board how he wanted the blacksmith to make it. He would do his own shaping, turning and drilling and finally assemble the work at the bench. To the individual this is much more interesting than one particular piece of work, for it has the spice of variety about it, but, of course, it cannot be termed efficient as to production. So it has yielded to the methods brought about by better machinery and preciser measuring tools. The old-time all-round man, however, may now be kept to one machine or process, and thereby be prevented from realizing the full value of his experience. On the other hand, the machinist who specializes becomes more rapid and accurate and probably drifts into some phase of work at the lathe or milling machine or at the bench, where he finds ample scope for his manual skill, his eye and his brain.

There is, and always will be, a place for all-round machinists; in the small shop, where there is not work enough to keep a man for each kind of machine; in the repair shop of larger works, where he may have to do anything from facing a slide valve to hanging a countershaft; and on experimental work—in fact, wherever there is frequent variety. For the position of foreman, a man with a broad experience is generally required, and here the all-round man will serve better than the specialist, provided that he can accept responsibility. It is also generally agreed that the bench hand has a wider outlook than the man at the machine, for it falls to his lot to interpret the drawings, sublet the machine work, and assemble the parts.

On the whole, therefore, it does not appear to me that the standard of the machinist trade is being lowered, as the matter tends to adjust itself. Relatively fewer all-round machinists are being produced, but proportionately fewer are required, and the standard of the work of the average machinist is continually being raised by the demand for more accuracy in machine manufacture.

Can We Improve Present Conditions

Can we improve present conditions or raise the standard of the machinist or toolmaker? is a question which could be asked. To this I would say, that to remedy the present tendency to over-specialize, the machinist should be given as much variety of work as is consistent with good production, to maintain his interest. Much can be done by employers to cure the tendency and prevent too-early specialization, by having a well-regulated system of apprenticeship. There is no doubt that love of the vocation in which a man is engaged breeds both efficiency and contentment of mind. Hence boys of good education who are interested in things mechanical should be encouraged to serve a definite term in learning the machinist trade. They should follow a schedule of changes from one machine to another, and have a good spell at the vise.

Technical training should not be undervalued, and the youth who acquires some knowledge of mathematics, mechanics and drawing in his own time will value it more than if it is given gratis by his employers. The wages during apprenticeship should have sufficient margin above the cost of board and lodging, so that the apprentice will not be tempted to drop his prospects of becoming a skilled mechanic with chances of promotion, for the higher initial pay of the machine hand on piece work.

By the end of his time the apprentice will have discovered his preference for some machine or class of work; or, if his inclination for the technical side is strong enough, he may push his way into the realms of machine design. In any case his varied apprenticeship will give him a good foundation for a successful career in a skilled and useful calling.

MARKET DEVELOPMENTS

Premium Steel Mills Let Down the Prices

Some Business Going Their Way for Spot Delivery, But the Price is Better Than for Some Months—Cancellations Are Asked for in Some Lines, But Are Not Generally Being Granted.

THERE are signs that the deflation of prices is settling more seriously on the iron and steel markets than for some weeks past. Not that there has been any sudden drop, but there is an eagerness to sell now that has been absent for some time past. The premium mills in United States are still selling steel in Canada, but they are doing this at a much more favorable price than formerly.

Cancellations are asked for in some lines, but about the only chance of having a cancellation recognized is when shipment has been delayed so long that it has become unseasonable. In that case consideration is often given. Otherwise requests for cancellation are receiving little sympathy. The trade holds that, were they allowed, it would leave a lot of unsaleable material on hand. The policy of no cancellation is being adhered to in the iron, steel and tool field in almost every case. One moderation is that some of the firms will defer shipment to anything within reasonable time, if by so doing they are going to benefit their customer. In many cases firms report that they have no requests for cancellations.

The fact that the National Machine Tool Builders' Association is meeting about a month sooner than scheduled is seized upon by many critics to indicate that there will likely be some announcement following such a gathering, although the association does not exist for any such purpose. Some of the builders have little business left on their books. In Canada machine tool builders are still fairly well employed, especially those engaged on heavy work.

The scrap metal market in Montreal was cut down this week on all lines, but even at the new figures there is nothing more moving. The new metal market is easier in many lines, and reductions in prices have been made at selling points.

Reports on collections vary. Some firms tell of trouble in getting their money, even from large and substantial companies, while in other cases the financiers will tell you that they have no trouble at all in this matter.

MONTREAL SCRAP METAL PRICES ARE CUT; BUSINESS STILL DULL

Special to CANADIAN MACHINERY.

MONTREAL, Nov. 4.—There is little doubt that the present easing of prices on many commodities is the commencement of that period of readjustment that the trade, and the public generally, has been looking forward to ever since the signing of the armistice. At different times during the past two years there have been developments that gave promise of a return to something like pre-war conditions, but the abnormal requirements for all classes of materials, which were excessive during the war period, continued throughout the succeeding year and showed little abatement until a few months ago. Trade conditions are now taking a turn where a lowering of prices becomes almost a necessity, but many circumstances combine in making it almost an impossibility to take drastic action in reducing quotations. The first real evidence of price cutting was reported recently when one of the mills in the States offered plates at $1 per ton less than they could be purchased elsewhere. When mills are openly taking an attitude of this nature it apparently foretells an early adjustment of prices to levels more in keeping to existing demand. Before any marked reductions can be made in steel prices it will be necessary for all concerned to co-operate in bringing about a fuller knowledge of what is required in removing the obstacles that at present prevent any marked reductions in the metal industry. There is a tendency on the part of labor to take a more reasonable view of conditions and production per man has shown an increase during the past few months.

Dealers Adjusting Prices

Steel mills have reached the point where actual competition is more than a by-word. Supply and demand are becoming real factors, with supply surpassing the trade requirements, the logical consequence being a marked trending to lower levels. Whether these reductions will be heavy or light is, at present, an unknown quantity, but the solution apparently hinges on the attitude of labor as to the question of wages. That labor is anxious to see a reduction in the cost of living is a well understood fact, but without their co-operation it is virtually impossible to establish a permanent basis of readjustment, as the present cost of production prohibits any excessive declines in the cost of producing nearly every necessity of industrial and domestic life. The pendulum of trade is swinging with considerably more uniformity as the supply of materials, which has been more or less restricted during the past year or so, is fast becoming normal. The sheet situation, since the collapse of the motor industry, has rapidly adjusted itself, and at the present time the supply of sheets, with the exception of brights, is almost adequate to trade requirements. Black sheets, 28-gauge, have declined, and local quotations are on a basis of $10.50 per hundred pounds. Plates are quite plentiful with delivery good; warehouse stocks may be had at $6.50 for 3-16 inch, and $6 for ¼ inch up. Tank plates, Pittsburgh, are now quoted at $3.50 and dealers here are revising prices to conform to the new American base. Boiler tubes are still scarce and prices are firm.

Conditions in the general industrial field are reflected in the metal market and price declines are in order. The quiet character of the demand has become additionally emphasized, and the present trading is quite listless. The local trading has decreased despite the lower price levels, and this is due to the lighter demand together with greater available supply. While dealers are still of an optimistic turn of mind there is a feeling that the remainder of the present year will see still further readjustment of conditions that will tend toward temporary trade depression. Quotations on copper have declined about 3 cents per pound. Lake is quoted at 21 cents, electro at 20½ cents, and castings at 20 cents per pound. Tin is now selling at 50 cents, a decline in a couple of weeks of 4 cents per pound; demand is lighter. Spelter is firm at 9 cents with a tendency to weakness. Lead is weak and requirements light; dealers are quoting 8¼ cents per pound. Antimony is down 1 cent to 8½ cents per pound. Aluminum is steady at 36 cents per pound.

Prices Decline on Light Demand

Aside from light local activity on the part of iron foundries, the old material situation has little of an interesting character and trading is exceeding light, almost to the point of being stagnant. The price decline has been little inducement for the consumer to come into the market as his requirements do not call for large quantities of scrap. The movement of old materials is dependent on the activity maintained in every class of industry, and with this activity showing marked signs of falling off the requirements for scrap are relatively reduced. Dealers here anticipate a quiet period until the turn of the year, and do not look for any heavy buying until well on toward the spring. All lines of scrap have been marked down by local dealers. Coppers are now quoted at 12 cents for light, 15 cents for heavy and wire. Brasses are down from 2 to 3 cents per pound. Price reductions are also general in steel and iron scraps, these declines ranging from 50 cents per ton on boiler plates to $4 on cast iron borings. Intermediate revisions are listed in the selected market quotations.

POINTS IN WEEK'S MARKETING NOTES

Montreal scrap metal market has been marked down all along the line, but no more business resulted, and trading there, as in Toronto, is very dull.

—

Some of the dealers are still buying from the premium mills, but the prices paid are much more reasonable; for instance, black sheets being secured for about 6.50 against as high as 7 and 8 a short time ago.

—

The National Association of Machine Tool Builders have advanced the date of their meeting almost a month, holding it early in November. Some announcement regarding prices and selling policies is expected to follow this session.

—

Some of the builders of machine tools in Canada are still well employed, and contrary to reports in the market they have not laid off men, neither have they decreased wages.

—

Small tool trade is quiet, there being few orders of any size going. Reports indicate that there may be some change in prices, especially of high speed within a few days.

—

The production of iron and steel is going down, and for the month just closed was not over 90 per cent. of the totals done in August and September.

—

Current prices for pig iron this week at Pittsburgh are: Basic, $40; foundry and Bessemer, $45. These prices show a decline, but even at these levels selling is very limited.

—

Warehouses report a good volume of business in most cases, while one goes so far as to state that the month just closed, October, was as good as any during the year.

MAKE IT HARD TO CANCEL ORDERS

Firms Believe That There Should be An Adherence to Contract Wherever Possible

TORONTO.—There are certain lines of business reporting a good turnover now, while others claim that business with them is quiet. No large sales are reported, although the wood-working end has turned in some fairly good orders. There can be no denying the fact that buyers of machine tools are asking more and more what is going to be the attitude of the builders in regard to prices. The fact that the annual fall convention of the National Machine Tool Builders' Association has been advanced from the first week in December to the first week in November gives strength to the theory that there is an anxiety to get together and discuss matters of policy, especially having a bearing on the schedule of prices. It is only natural to expect that in such an atmosphere buying is going to be rather dull.

Need New Equipment

"Constructive selling in the Canadian field is hard work," is the opinion of one well-known manager this morning. "Our men have worked out several problems showing where they can give far better results than are now being secured by older methods, but it seems very hard to make much progress in this way. The Canadian manufacturer has a liking for getting the last final kick out of every old machine there is in the plant, no matter whether it pays him to do it or not. Many of the plants here will have to mend their ways if they are going to stand the pace with some of the newer plants that are being out in here now."

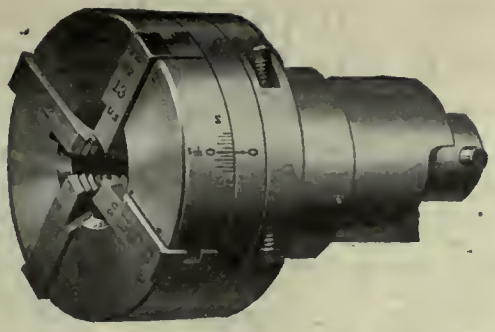
Another machine tool man, who has just returned from a rather extended survey of the field, claims that many buyers—or firms that should be buyers—are waiting and putting off coming into the market just as long as they can. They think they can secure something better in the way of terms or conditions or prices, and for that reason they are not buying. The business they have to offer is good, and it is not going to go out of existence, but it is not helping in the meantime to keep up the volume of trade.

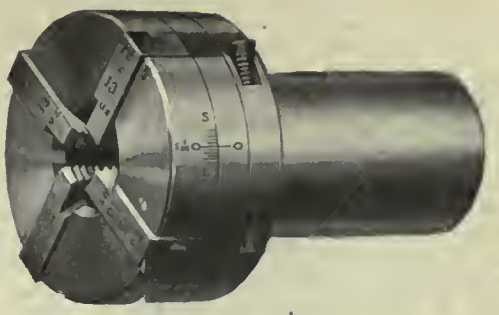
About Cancellations

Some of the warehouses are receiving requests for cancellations, especially in business that has been on their books for some months. The policy of some of the firms is quite well marked on this point, and one that seems to take in quite a number of others was set forth as follows: "We do not accept cancellations but we will make postponements in shipments, and do anything within reason to make it easier for a man to take on his obligations and settle for them. If we were to start accepting cancellations we would be lost in a very short time. It would mean that we could go ahead and turn out material, finance it, and then, when ready to ship, we would find that our market had gone and the stuff was left on our hands. There is nothing worse for business in general than that we should make it easy to start a procession of cancellations. One cancellation is sometimes enough to start a whole lot of others in operation, and for that reason we do all in our power to keep the first cancellation in the ring from being made."

Here is the opinion of another man in the steel merchandising business: "We have some requests for cancellations but they are neither numerous nor serious, nor do we expect them to become so. Most of them are on material that has been on our books for some time past. If it is possible for us to make arrangements with our principals to cancel we will do so, but otherwise we insist that the business stand. Some of the material that cancellations are asked for has a seasonable value that is apt to be spoiled by our inability to secure it soon enough. In such a case we are willing to give every consideration to the request. Of course we try to get it held over for the next season if possible. Just a few days ago we had a request for a cancellation on a big piece that had been

428





Geometric Solid Adjustable Die Heads

When one uses the word "ONLY," he needs to be sure of what he is talking about. With confidence we use the word in saying that a Geometric Solid Adjustable Die Head, fitted with a set of milled dies, is the only solid die head that will back off without stripping the thread.

Geometric Solid Adjustable Die Heads may be fitted with either a releasing shank, plain shank, or with special shank for the Gridley Automatics. The releasing shank permits the head to disengage from the shank upon completion of the thread. The plain shank fits the head for use on the turret of a lathe or on a live spindle, such as a drill press.

Apart from the fact that it is not equipped with the self-opening feature or the roughing and finishing attachment, the Geometric Solid Adjustable Die Head is the same in principle and construction and will do equally as accurate work as the other styles of Geometric Die Heads.

Whatever the requirements, there is a type of Geometric Die Head best adapted to the work.

THE GEOMETRIC TOOL COMPANY
NEW HAVEN CONNECTICUT

Canadian Agents:

Canadian Fairbanks-Morse Co., Ltd., Manitoba, Saskatchewan, Alberta.
Williams & Wilson, Ltd., Montreal. The A. R. Williams Machinery Co., Ltd., Toronto, Winnipeg; St. John, N.B.; Halifax, N.S.

specially forged, and which had cost the forging plant a lot of money. There was only one thing to do in such a case, and that was to insist that the firm ordering the work should meet its full obligation, and I think that standard is generally accepted."

Most of the warehouse men report that they are doing a satisfactory business. One of them told Canadian Machinery that the month just closed (October) would be one of the very best in the whole year. There is still a good demand for sheets, and some of the dealers state that they are still taking on material from the premium mills, but the premium mills have come down in their price to some extent. Some of them, it is said, are doing as well as 6.25 on black sheets for the Canadian trade, and on blue annealed one quotation gave 5.90.

In tubes there is still a big demand and enough bookings to take care of all the shipments that come in for weeks yet.

Some peculiar reports get in circulation in the machine tool market. This paper was told in all seriousness that one well known maker had laid off a number of men, and was generally slack. Within an hour or so a representative of this paper met one of the officials of this company on the street and put the question to him. The answer was that they had not laid off a man and that the factory was comfortably busy.

The Small Tool Business

Buyers are not taking on very much just now in the way of small tools. They are buying just what they need. In some cases one will hear of a fairly large user buying a dozen or so of a standard and much-used size of drill cutter, or tap, while in ordinary times the buying would be done by the gross. There are rumors in the market this week of some readjustment in the prices of certain lines of high-speed tools, and it is likely that an announcement will be made shortly in regard to this.

Several lists are in the market from firms that find they have on hand more stock than they can make up profitably. Buying was done at high speed in times when material was short, and there may have been more or less pyramiding of orders. Now the jobbers are being appealed to to place some of this overstock. As a general thing the jobbers just now have all they can handle, and are not likely to take on anything unless there is a very attractive price clause attached, and this is just the thing the manufacturers are trying to avoid. In many cases they know they cannot make their material up and get their money out of it in the ordinary way.

Dealers in small tools state that the general stock is getting fairly low in the country and that outside of a few industries that bought in excess of their requirements there is a lot of business that will undoubtedly come into the market before many months.

ORDERS ARE NOT COMING IN AND THE BUSINESS IS NEEDED

Special to CANADIAN MACHINERY.

PITTSBURGH, Nov. 4. — There has been a further decline in steel production, the rate now being not over 90 per cent. of the average rate in August and September. The Steel Corporation is operating its various plants as well as car supplies and fuel supplies permit, and a few of the large independents are doing almost as well, but some large independents and the great majority of the smaller mills have begun decreasing output in the past week or two, or have carried farther a decrease already begun. In a few instances mills are operating at only 50 or 60 per cent. of capacity.

With many of the mills that have decreased production the cause is simply that the mills have largely run out of orders. These are mills that sought the highest possible prices, and necessarily had to keep their order books relatively clear so as to be able to make the deliveries that brought the highest prices. When the market turned dull these mills could not fill their order books by reducing prices because sufficient business was not available at any price.

With the other mills the case is one of cancellations and postponements of delivery. The mills seemed to be sold up for several months, but cancellations and postponements have made quite a hole in the weekly requirements of customers. Mills in this position are indisposed to cut their prices, as they still have a large volume of business ahead, though not for as heavy deliveries week by week as they could make by operating full. It would be disadvantageous for such mills to cut prices, since that would jeopardize the contract business on books and would not bring enough new business in to make up.

Steel Price Changes

The independent reported a week ago as having put out a price of 2.35c on merchant steel bars, equal to the Steel Corporation price, has since withdrawn the price, and is now quoting 3.00c, without having booked a great deal of business at the cut. This illustrates how little business can be gotten by the mills that are maintaining prices. Quotations commonly run from 3.00c to 3.25c, these prices being adhered to for the sake of protecting contract business on books.

The plate mills still call 3.25c the general market on plates, but admit that it is practically impossible to obtain more than 3.00c. In actual competition this price is shaded, the lowest priced transaction lately reported being one involving 3,000 tons at 2.85c. Western mills, however, have been quoting a lower Pittsburgh basis than this, but would not ship eastward, as that would be against their freight.

Black sheets are now available from several independents at 6.50c, if the specification is at all desirable. On galvanized 8.75c has been done, but this is considered exceptionally low, 9.00c being a more common quotation. Blue annealed can be had on the basis of 5.00c, except perhaps for gauges 14 to 16.

The American Sheet and Tin Plate Company will probably open its order books before the end of the month for first half contracts with manufacturing consumers and first quarter with jobbers. On account of restricted operation the company will carry considerable business into the new year that was booked for the present half year, probably about two months of work in sheets and three months in tin plate. Customers' allotments for the half year will be correspondingly restricted, making the tonnage carried over plus the new contract equal a half year's estimated requirements. As is customary, the independents are expecting, or at least hoping, that the Steel Corporation will advance its prices on sheets and tin plates, but there is no indication whatever that any change will be made from the prices adhered to since the Industrial Board adjustment of March 21, 1919, these prices being: Blue annealed sheets, 3.55c; black sheets, 4.35c; galvanized sheets, 5.70c; tin plate, $7 per base box.

Coke and Pig Iron

Connellsville coke for spot shipment has continued its decline in the past week. Last week's report recorded a decline in spot furnace coke from $17 to $14, while at this writing the market is down to $10. Foundry coke, which had declined only slightly, has been declining more rapidly and is now down to $13. It lags behind furnace coke in the decline but will no doubt eventually show the natural differential above furnace coke, which is hardly more than $1 a ton, if as much. The decline in spot coke is due to so many furnaces having banked or blown out, or deciding to do so in the very near future, whereby shipments on requirement contracts had to be curtailed, leaving more coke to be offered in the spot market.

There is much speculation now as to where coke will stop in its decline, but there is very little foundation for making predictions. While some observers seem to think that because coke sold at $18 to $19 last August it cannot decline more than so much below that level, there is no definite percentage named as permissible under market conditions. On the other hand, coke sold at $1.50 in May, 1915, and at $3.60 in April, 1919, just after the Industrial Board adjustment in pig iron and steel prices. One theory is that coal is going to find a level at about $4, and that this will put

Aikenhead's

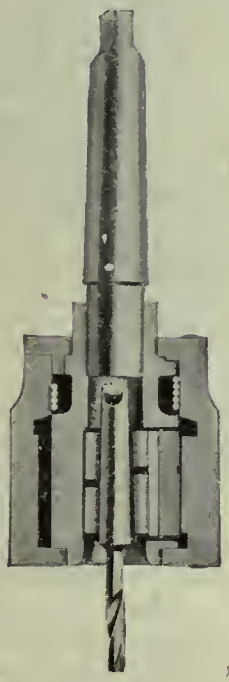
"Everything in Tools"

Get all your tools from Aikenhead's, "Canada's Leading Supply House." Your requirements will be promptly and carefully filled.

If you have never ordered from Aikenhead's, send your next order to them. You will find the quality, price and service right!

Full particulars of these or any other tools upon request.

Wahlstrom
Automatic
Tapping Attachment



The Wahlstrom Automatic Tapping Attachment is ten times faster than hand tapping and its simple to and fro motion frees the lands of chips, thus preventing jamming and tap breakage.

The Wahlstrom is constructed of hardened and ground parts and has nothing whatever that can get out of order. It is manufactured in two sizes. No. 1 takes taps of all sizes from 5-40 to ½-inch standard. No. 2 takes taps from ¼ to ¾-inch.

Wahlstrom Chuck
Grips the Entire Shank. Never Slips

Because the Wahlstrom Chuck grips the entire shank you may use numbers 1, 2 and 3 M. T. Shank Tools, whether they have a tang or not. The cam action is such that the resistance of the tool governs the gripping power of the jaws. Slippage is impossible.

Automatic and instantaneous in action, the Wahlstrom Chuck makes every minute and every movement profitable. The operator can make any change of tools in two seconds without stopping the spindle, simply by grasping the loose shell of the chuck.

Wahlstroms are made in two styles—one for straight shank tools, the other for M. T. shank tools—and they are both automatic. BUY THEM AT AIKENHEAD'S.

Aikenhead Hardware, Limited
17 Temperance Street, Toronto, Ont.

If interested tear out this page and place with letters to be answered.

coke at about $7, on the basis of its requiring one and a half tons of coal to make a ton of coke, with $1 for the conversion.

While everyone agrees that pig iron is going to decline until it finds a stable level, the market only makes an occasional step towards the requisite readjustment, inquiries being so infrequent that furnaces have little temptation to reduce their quotations. Basic remains quotable at the reduced price of $40, valley, reported a week ago. Foundry and Bessemer have each declined $2 in the week, to $45, valley. The decline in foundry quotations was precipitated by an inquiry for 200 tons for delivery at Pittsburgh. Several valley furnaces tried to get the order by quoting $45, furnace, or less, but a lake front furnace is understood to have gotten the business by making a still lower price. Bessemer declined to $45 without any transactions being reported, the case being simply that a producing interest offered iron at the $45 level.

One valley furnaceman predicts that pig iron will recede to the Industrial Board schedule of prices, evidently on the basis that in steel the Steel Corporation has remained on the Industrial Board schedule and the independent prices are universally expected to come down to the Steel Corporation level. Industrial Board prices were $25.75 for basic, $26.75 for foundry, and $27.95 for Bessemer, these prices being, generally speaking, f.o.b. furnace. No other producer admits that pig iron will get as low as that, the common prediction being that pig iron will drop to between $30 and $35. This probably means $30. There is good ground for argument that decline in steel prices to the Industrial Board schedule does not prove that pig iron should decline correspondingly, for the Industrial Board schedule, reflecting the philosophy that obtained in fixing prices during the war-time control, put a rather larger percentage spread between pig iron and semi-finished steel, and between semi-finished steel and finished steel, than has obtained under open market or competitive conditions.

MACHINE TOOL BUILDERS ARE PUTTING THEIR MEETING NEARER

Special to CANADIAN MACHINERY.

NEW YORK, Nov. 4.—The annual fall convention of the National Machine Tool Builders' Association has been brought forward from the first week of December to November 11 and 12. This change of dates is presumably for the purpose of giving the machine tool manufacturers an earlier opportunity to consider the present business slump so that a plan of action may be suggested that will best meet the situation.

Three questions of importance face the machine tool trade: First, the business outlook for next year; second, the question of reductions in selling price, and third, the possibility of a revision downward of labor costs.

As for the first, it may be said that the trade as a whole is very optimistic regarding conditions in 1921, but the outlook for the remainder of this year is none too good, especially as it now appears quite certain that little or no railroad buying will be done before January 1. There is a fair number of inquiries for tools from industrial plants, but prospective buyers seem in no mood to close business. Individual opinions in the trade are that price reductions at this time will not stimulate much buying. However, the pressure that has been brought to bear by some buyers, particularly automobile companies, for lower prices has resulted in serious consideration on the part of many machine-tool builders as to whether prices can be brought down. Material costs are coming down, but these reductions have not as yet been reflected to any extent in machine tool manufacture. Likewise, some plants are bringing down labor costs by insisting upon greater individual efficiency among workmen, but this reduction is offset to some extent by the fact that few plants are working full time.

While the National Machine Tool Builders' Association does not, and cannot, consider the question of selling prices officially, it is quite probable that the gathering of many machine tool manufacturers in New York this month will result in informal conferences on the subject, and the members of the association will go home with some definite idea as to what should be done to meet the present situation.

WARN USERS WHEN JUICE RUNS LOW

St. Catharines Having Trouble in Securing Power for its Industries

St. Catharines.—The local Hydro power crisis, precipitated when on account of the cold spell customers threw on their electric heaters despite repeated warnings, and burned out half of the transformers, is somewhat easier, due to co-operation on the part of consumers, which has been to an extent forced.

For two days some of the smaller factories have been cut off and an effort will be made to have the street lights reduced to half and illuminated signs eliminated.

Manager Yates, explaining how the load has been reduced thus far, said: "If at any time a reduction is necessary the signal will be flashed to all the users, as was done last night by successively pulling out the switches feeding the different sections of the city. That section which shows the least response to the signalled request will be the one allowed to suffer."

AMERICAN CO. IS NOW INTERESTED

And Reorganization of the Beaver Motor Truck Co. Has Been Announced

The announcement that the American Axle Company, capitalized at $6,000,000. had become heavily interested in the Beaver Motor Truck Company, of Hamilton, and in future would supervise the operation of the local factory, has been made. The American Axle Company operates axle and truck plants in a number of American cities and is rated as the largest exclusive manufacturer of worm drive axles in the world. The American company has become heavily interested in the Beaver Motor Truck Company and will supervise the operation of the local factory.

Under the scheme of reorganization, H. R. Williams, who organized the original Beaver Truck Company, becomes president and general manager, with E. W. Macavay, president of the American Axle Company as vice-president. Captain Harry Trenaman has been appointed treasurer, while William Mulvaney, E. D. J. Stares, W. H. Dawson, of the T. Eaton Co., P. C. Wolf and P. J. Schultz, of the American Axle Company, are the new directors. The reorganization of the local companay is expected to prepare the way for some big things. Plans are now under way to turn out 3,000 trucks during the next twelve months, while arrangements are being made to place a new model on the market.

MORE CAPACITY FOR WIRE MILL

Steel of Canada Making Important Additions to Existing Plant

When the buildings now in the course of erection are completed, the capacity of the wire mill of the Steel Company of Canada at Hamilton will be doubled. The plans call for duplicating the capacity of the pickling room, annealing department, and also of the coppered wire department. The latter will then be capable of turning out 200 tons of finished wire per day, which will make it the largest wire mill in Canada. In addition to these extensions there is also being erected a large storage shed, steel construction throughout, equipped with travelling crane for handling raw material in the most economical manner.

INDUSTRIAL NEWS

NEW SHOPS, TENDERS AND CONTRACTS PERSONAL AND TRADE NOTES

TRADE GOSSIP

Equipment Wanted.—T. McAvity & Sons, Ltd., St. John, N.B., are in the market for a few No. 6 turret screw machines.

Locating in St. Thomas. — The Canadian Edison Phonographs, Ltd., have taken over the buildings in St. Thomas, formerly occupied by St. Thomas Cabinet, Ltd., and before that by Thomas Bros. The Edison Company took over the buildings, much of the equipment in the woodworking shops, and get six acres of land along with it. They have also placed orders for considerable new equipment in the line of woodworking machinery. The deal for the sale of the plant to the Edison Company was put through by Mr. William Garlock, of the Garlock-Walker Co., Toronto.

George A. Marshall, of Messrs. Marshall, Son & Bunney, 39 Richmond St. E., Toronto, has gone to England on the SS. Metagama, where he will spend a month or more on business matters.

Will Finish Ships.—Arrangements are being made by the Department of Marine with the liquidator of the Dominion Shipbuilding Co., of Toronto, for the completion of the two steamships which that corporation had under construction for the Government of Canada. The vessels, which were being built for the fleet being operated by the Canadian Government Mercantile Marine, are to be of 3,500 tons each, and about 75 per cent. of the work upon them had been done when the company went into liquidation. The Department of Marine will either undertake to do the remainder of the work or have it done through the liquidator.

May Earn Less.—In commenting on the business prospects, President T. J. Dillon, of Canada Foundries & Forgings, Welland, Ont., says: "In order to realize on the full possibilities of the plants this company found on its hands at the end of the war, it was considered advisable to appropriate a fairly large amount for additional equipment for rounding out their different units to lower the cost of manufacture of regular lines and add a few new ones. Indications point strongly to gradually lowering on steel commodities, and lessened dividends, which will result in declining earnings. Although the common dividend declared was somewhat less than those previous, it makes 10 per cent. for the year 1920."

J. F. MACKAY WITH MORROW COMPANY

Formerly Business Manager of Toronto Globe and Latterly With The Willys-Overland Co.

J. F. MacKay, formerly business manager of The Globe and latterly secretary and treasurer of the Willys-Overland, Ltd., has resigned his office with the latter company to become vice-president and general manager of the

J. F. MACKAY.

John Morrow Screw & Nut Co., Ltd., of Ingersoll. He will also occupy the position of vice-president of the allied industry, the Ingersoll File Co., Ltd.

This and other important changes are consequent upon the retirement of J. Anderson Coulter from the presidency of the two companies. Mr. Coulter has been actively connected with the progress of the industry for more than thirty years. The directors announce the election of Col. F. H. Deacon, of Toronto, as president; he has been vice-president of the companies. The other appointments are: Assistant general manager and treasurer, H. P. Stoneman; sales manager, F. N. Norton; secretary, Lt.-Col. H. L. Edmonds.

As to his successor in the important positions he has held with Willys-Overland, Ltd., no announcement has been made, but it is understood that the directors will ratify an appointment within the next week.

POWER CAUSES MORE TROUBLE

Industrial Centres Have Hard Time in Keeping Their Plants in Operation

BRANTFORD.—The Hydro Commission here has been unofficially notified that a 20% reduction in Brantford's Hydro allotment will be made shortly. A conference of manufacturers and the local Hydro Commission will be arranged to take steps to prepare for the cut. The situation here is already serious and the city council committee in charge of street lighting is prepared to curtail this to provide more power for domestic users.

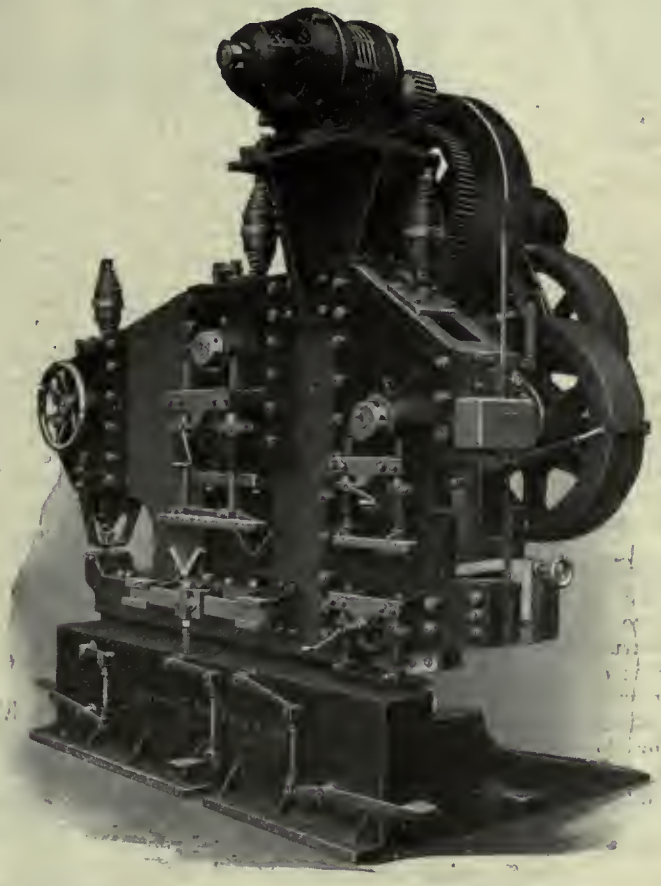
Windsor's Shortage

WINDSOR.—Deeming it necessary to bar use of Niagara power for signs and window lighting, the Windsor Hydro-Electric Commission will ask the city council to pass a by-law giving effect to a resolution passed at a meeting of the commission. O. M. Perry, manager of the local commission, said every effort will be made to discourage the use of electric heaters. Co-operation is necessary also on the part of business men, Manager Perry said, in order that street lighting may be provided in new residential sections.

New Incorporations. — Incorporation has been granted to the following: United Shoe Repair Shops, Ltd., Montreal, $50,000; Canadian Feature and Production Co., Ltd., Winnipeg, $1,000,000; The Bee Starch Co., Ltd., Montreal, $100,000; Canadian Harvester, Ltd., Toronto, $40,000; Canadian Skirmisher, Ltd., Toronto, $40,000; Canadian Rover, Ltd., Toronto, $40,000; Pacific-Atlantic Construction Co. Ltd., Vancouver, $5,000,000; The Davies Studios, Ltd., Montreal, $49,000; The Live Fish Co., Ltd., Quebec, $50,000; Cosmo Cotton Company, Ltd., Yarmouth, N.S., $600,000; Copeland Hotel Co., Ltd., Pembroke, Ont., $100,000; Sheffield Engineering Supplies, Ltd., Montreal, $50,000; Canadian Highlander Ltd., Toronto, $40,000; Canadian Libbey-Owens Sheet Glass Co., Ltd., Toronto, $1,680,000; Canadian Queen Manufacturing Co., Ltd., Vancouver, $100,000; Canadian Challenger, Ltd., Toronto, $40,000; Canadian Logger, Ltd., Toronto, $40,000; Commercial Investigators, Ltd., Montreal, $50,000.

Steel Frame Quintuple Combination Punching and Shearing Machines

In Stock for Immediate Shipment



The Ryerson Steel Frame Quintuple Combination Punching and Shearing Machines embody five metal-working machines in one unit. These machines will handle the shearing of plates, round and square bars, coping and notching, section cutting and punching, without changing any tools or attachments.

We are manufacturing these machines in six sizes, with various capacities, covering a range of work from that of the ornamental iron and light structural shop to that of the heavy bridge-building plant.

The Week's Events in Montreal Industry

H. B. Smith, formerly president of the Northern Navigation Company, has been appointed managing director of shipyards for the Canada Steamship Lines.

Thos. Robb, secretary of the Shipping Federation, has sailed for Europe, where he will represent Canadian shipping interests at the meeting of the League of Nations to be held shortly at Geneva.

D. M. Brown, formerly office manager of the Montreal branch of the Holden Company, has been appointed manager of the Ontario division, with headquarters at Toronto. C. M. Gray will succeed Mr. Brown as office manager at Montreal.

The Montreal Chambre de Commerce has been considering the advantages that would follow the building of a tunnel under the Champ de Mars and Jacques Cartier Square, for the purpose of relieving the congestion that frequently occurs in this vicinity on market days and when traffic to and from the harbor front is excessive. No definite action has been taken but the project has been laid before the Administrative Commission.

At a recent meeting of the Montreal Branch of the Engineering Institute of Canada the entire evening was devoted to moving pictures, both of an instructive and entertaining character. One of the reels shown was in connection with the work of McGill University. Every branch of the work was covered by the film, including educational, athletic and military features. Between the showing of the pictures brief addresses were given by J. L. Busfield and the secretary, F. S. Keith.

Following a conference held between the Administrative Commission and an influential delegation of business men and citizens of Montreal, headed by Lord Shaughnessy, a deputation will go to Ottawa to confer with the Government on the question of constructing a second bridge across the St. Lawrence in the vicinity of the harbor of Montreal, to connect the Island with the south shore. It is felt by a large number that this additional means of communication between the two points is an urgent necessity and that the next few years will demand some relief from the present conditions.

At a recent meeting of the Montreal branch of the Rotary Club, F. E. Rejall gave an interesting address on high-speed steel, touching on the electric and crucible processes of manufacture. While intimating that considerable progress had been made with the electric furnace in this connection, he favored the crucible method, as the product thus obtained was more homogeneous and much better quality although much more expensive to manufacture than the other, owing to the ability of the electric furnace to take a charge of six tons and over, while an average crucible would contain from 60 to 80 lbs.

On Saturday last the Canadian Vickers Company successfully launched the Canadian Commander, the eleventh vessel constructed by this company for the Canadian Government Merchant Marine. The ceremony of christening was performed by Mrs. Ballantyne, wife of the Minister of Marine and Fisheries. This new addition to the National fleet is a steel vessel of 8,350 deadweight tons, 413 feet long, 53 feet beam, and 31 feet deep. The vessel was built under the supervision of C. F. M. Duguid, of the Department of Marine, and W. J. Alderson, representing Lloyd's Register of Shipping. The boat is equipped with triple expansion engines and Scotch boilers fitted with Howden's forced draft system.

The Montreal Board of Trade at a recent meeting had before it a communication from the Jamaican Boards of Trade in which those bodies had passed resolutions endorsing the movement to increase trade relations between Canada and the British West Indies. The letter pointed out a number of impediments to trade which would require adjustment before further action would be taken. The chief obstacle is the present so-called "16 Dutch" standard and color test on Jamaican sugar coming into Canada. The West Indies Boards of Trade are also in favor of a mutual preferential tariff, which, they claim, would not only cement present friendly relations but contribute to a large degree in the extension of trade between the two countries.

The Canadian Vickers Company of Montreal has recently received word from the aviation branch of Vickers Limited of England that the parent company has been awarded first prize of £10,000 as the winner of the amphibian class of aeroplanes. The "Viking" machine was designed by Mr. R. K. Pearson, who also designed the famous and successful "Vickers Vimy." The Viking is fitted with a 450 h.p. Napier engine, is capable of carrying five passengers at a speed of 120 miles per hour, and can be landed on water and driven ashore without any special slipway. It is worthy of note that this is the fourth big prize won by Vickers machines in air or air and water competitions. These include the prize of £10,000 won by the late Sir John Alcock in his flight across the Atlantic, and a like prize won by Sir Ross Smith in his London to Australia flight. It might be well to mention that extensive experimental work has been constantly carried on by the Vickers Company since the armistice in the development of air machines and that the expenditure in this connection far exceeds the amount of the prize just awarded.

BUSINESS PAPER EDITORS' MEETING

Interesting Sessions in New York Followed by Election of Officers

Clay C. Cooper, Mill Supplies, Chicago, was elected president of the National Conference of Business Paper Editors for the ensuing year at a meeting held in connection with the annual deliberations of the Associated Business Papers, Inc., at the Hotel Astor, New York City, Oct. 20 and 21. The other officers chosen were: Vice-president, C. J. Stark, The Iron Trade Review, Cleveland; secretary-treasurer, R. Dawson Hall, Coal Age, New York. The executive committee is composed of A. I. Findley, Iron Age, New York; C. T. Hawson, Railway Maintenance Engineer, Chicago; A. R. Kennedy, Canadian Machinery, Toronto; James H. Stone, Shoe Retailer, Boston; H. L. Parmalee, Metallurgical and Chemical Engineering, New York; and Arthur L. Rice, Power Plant Engineering, Chicago.

FIRMS LOOKING FOR CONNECTIONS

MAY BE SOME ITEMS HERE YOUR FIRM CAN SUPPLY THEM WITH

By communicating with this paper and mentioning key numbers, information can be obtained by firms interested in the following lines:

2118. Tree-Felling Machinery. — A London company have an enquiry for tree-felling machines and would be glad to hear from Canadian manufacturers with catalogues.

2119. Hardware, etc.—A commission agent in Barbados, in good standing and representing a number of English firms, is desirous of obtaining a Canadian connection for general hardware, including such lines as valves, stop-cocks, etc., for machinery, also nails, locks, etc.

2229. Iron and Iron Products.—A firm in Jassy, Roumania, is desirous to receive quotations c.i.f. Roumanian port as well as other particulars from Canadian firms in a position to export iron and iron products, tools, utensils, stoves, etc.

2230. Steel Baling Wire.—An Ormskirk firm asks to be placed in touch with exporters of Canadian grain and steel baling wire used for pressing hay and straw by steam.

When we work hard with our body all day our backs ache and our muscles ache. This is all right, for nature has given us sweet, refreshing slumber to drive away the aches and pains so that on the morrow we are ready for the fray.

GUELPH, ONTARIO

PORTABLE BOATS OF EARLY RAILROAD PRACTICE

(Continued from page 417)

Gay notes that the number of engines in service had increased to 17, ten of which were manufactured by M. W. Baldwin; five by Robert Stephenson, of England; one by Coleman Sellers & Sons; and one by Long & Norris. Commenting upon the engines, he says:

"The two latter have been but recently put upon the road, and their capacities are not yet fully tested; they are, however, believed to be excellent engines. The engines from Mr. Baldwin have all been tested and found to be of the first class. The five engines imported from England are not as efficient as those manufactured in this country; the workmanship of them is good, but many important parts of the machines are too light to enable them to encounter (with a heavy load) the high grades and severe curves on this railway, in consequence of which frequent repairs are required upon them."

(To be continued)

FACTS REGARDING THE OXY-ACETYLINE PROCESS

(Continued from page 422)

repair was comparatively low. This casting was broken through the middle and by looking closely the welded section may be seen.

Fig. 2 illustrates a gas engine cylinder weighing 1,500 lbs. that got cracked by frost. Again the outlay to replace would have been considerable, and the cost an item to be seriously considered, but welding proved the solution. In 48 hours the engine was dismantled, the bed welded and the engine re-erected ready for service again.

Consider the case of Fig. 3. This was a nail machine bed that broke through the middle and looked like a serious matter for a while. In 48 hours, however, the machine was again fit for service and the repair made at very little cost.

The next example, Fig. 4, depicts the face plate of a large wheel lathe, which was used for machining locomotive drive wheels. It became broken by accident and represented a loss of some hundreds

Machine Tool Builder Knew the Facts and Was Able to Help Out

AN automobile maker—and this was in the Canadian field—after the lowered prices had been announced on cars, called on a number of the firms with which he was doing business into conference and explained that it was desirable from his point to have lowered prices on the things it was necessary to buy in order to make cars at the new prices.

These meetings lasted for several days, and very little progress was made. Most of those called in had no intention of altering their prices. One maker of machine tools had the facts presented to him. He knew all about the business that the firm had, and he also knew much of the design of the machines that were being made.

When the proposition was put up to this firm to improve in the matter of price their representative was ready with a real suggestion, based on a knowledge of the construction and design of the special machines that the automobile shop was securing from his factory.

His proposition was soon stated: "Yes, we can change the price of the machine if you agree to alter the design in such a way that it will allow us to give you a machine that will serve your purpose just as well at a lower figure."

This was a new one to the automobile man, and he had not been looking for such a thing. He at once called in his designers and a draftsman, and together with the representative of the tool builder they went over the machines that were on order. The machine tool man went right to the point at once and showed them where they were calling for dimensions that were so fine in some ways as to be very expensive in obtaining, and also convinced them that there was no necessity for this for the class of work required. He went carefully over the blue prints and drew attention to other details that were not necessary, but which had been insisted on by the automobile factory. The elimination of these and the general simplifying of the design would make it possible to reduce the price of the machine by a very fair margin, and as there were a number of these machines on order the total saving would amount to quite a respectable figure. It was also shown that the automobile factory would have a machine that would do the work required just as well as previously.

The result was that the business stayed on the books of the machine tool maker. The automobile firm was pleased, and their work will be done just as well as previously. The machine tool builder will get just as much profit as formerly.

And don't you suppose that the automobile man will be inclined to go back to that same firm of builders next time he wants to get some real service and some real help in order to assist him in meeting a new situation?

of dollars. Four hours was all that was necessary to have it again equal to new.

When a large flywheel of the size shown at Fig. 5 and weighing 3,500 lbs. is incapacitated from service, a serious loss must inevitably follow unless it is possible to repair it again quickly. This was done by oxy-acetylene welding as before, and the saving in time and money effected may be easily imagined and further comment is hardly necessary.

The next two illustrations, Figs. 6 and 7, show a Hart-Parry gasoline engine cylinder that weighed 325 lbs. It has a ten-inch bore. The views show it before and after welding, and the work in its entirety only took about three hours.

The remaining two illustrations, Figs. 8 and 9, depict an automobile cylinder before and after welding. For reclaiming such parts this process is ideal, and has saved many a dollar. There are, of course, hundreds, yes, thousands, of cases that could be quoted and illustrated showing how this system has proved of decided value, but enough has been illustrated to start the ball of thought arolling. We appreciate the courtesy of L'Air Liquide Society, who very kindly loaned us these illustrations, as examples of work performed. Oxy-acetylene welding is only in its infancy, and the chief thing to do is to have confidence in it, then follow up that confidence by actual use.

The Seneca Falls Mfg. Co., Inc., have recently acquired the business of the O. R. Adams Manufacturing Company, Inc., of Rochester, N.Y., which was organized about two years ago to develop and manufacture a new type of production lathe called the "Adams Short Cut." It is a compact, sturdy, geared head machine, capable of taking a cut said to be equal to the average 16-inch engine lathe, occupying less than one-half the floor space with a corresponding reduction in investment.

The Seneca Falls Manufacturing Company, Inc., are planning to consolidate the business of both companies at Seneca Falls, N.Y., where additional facilities will be provided to increase the manufacture of both the "Star" and the "Short Cut" lathes.

MACHINERY WANTED

WANTED IMMEDIATELY—1 30-TON LUCAS Forcing Press. Address all replies to Box 722A, Canadian Machinery.

WANTED—FIVE TO SIX HUNDRED H.P. CORliss engine, also 72 in. roller-band resaw; 250 tons 40 or 50 ft. rails; 5-ton locomotive crane; all must be in good shape. Apply N. J. McArthur, 325 Howe St., Vancouver, B.C. (cfm)

WANTED—8 IN. HORIZONTAL, 54 IN. AND 66 in. upright band resawa; steam engines, 35 to 125 h.p.; 36 in. gang aaw grinder, planers, edgers and sprocket chain, etc. R. C. Patterson, Smithville, Ont. (cfm)

WANTED—ONE VAN NORMAN USED DUplex milling machine; one 36x36x10 ft. used metal planer; 36 or 30 used 2 or 3 drum sander, Berliner or almilar machine; 14 or 16 in. used hand jointer; 12 in. wood lathe, used; 14 or 16 in. double end wood lathe, used; 18 in. pattern makers' disc grinder, double end, used. Box 725F, Canadian Machinery.

WANTED—A FEW NO. 6 TURRET SCREW machines. Box 726F, Canadian Machinery.

WHEN WRITING TO ADVERTISERS KINDLY MENTION THIS PAPER

POSITION WANTED

WANTED—BY A PRACTICAL FOUNDRYMAN with good technical training, position as foundry foreman. Can mix by analysis to suit all grades of castings and cannot be beaten on cupola practice. Am familiar with all modern foundry appliances and molding machines. McLain graduate. Reply Box 724, Canadian Machinery. (c20m)

WANTED—POSITION BY MECHANIC WITH good technical education and practical experience of eight years in pattern shop, six years in molding shop, three years in machine shop, and for the past two years superintendent of jobbing plant comprising pattern, molding, machine and forge shops. Box 727, Canadian Machinery.

PRACTICAL DRAFTSMAN AND ENGINEER, Canadian, shop, drafting and executive positions filled. Fifteen years' experience mechanical and structural. Wide experience on estimating, designing, steel plants, forging work, building construction. Married, 35, good reasons for desiring change. References submitted. Box 728, Canadian Machinery.

Electrical Equipment

WANTED—Circuit breakers, 2-3 phase, 2200 volt, 100 amp., oil switches for pipe mountings with overload release. 1-2 phase same as preceding. Frid Construction Co., Limited, Hamilton, Ont. (cfm)

PATTERNS

TORONTO PATTERN WORKS, 65 JARVIS Street, Toronto. Patterns in wood and metal for all kinds of machinery. (otfm)

BRANTFORD PATTERN WORKS ARE PREpared to make up patterns of any kind—including marine works—to sketches, blue prints or sample castings. Prompt, efficient service. Bell 'Phone 631; Machine 'Phone 733. Brantford Pattern Works, 49 George St., Brantford. Ont. (ctfm)

MACHINE WORK WANTED

MACHINE WORK WANTED FOR LATHES, shapers, milling machine and planer, etc. Hourly or contract basis. Prompt delivery. W. H. Sumbling Machinery Co., Toronto. (ctfm)

CANADIAN AGENTS WANTED

FOR HIGH-GRADE AMERICAN-MADE LATHE —14 to 26. In replying state territory you can cover and cover thoroughly. Box 682, Canadian Machinery.

FOR SALE

ENCLOSED LIQUID FUEL COMBUSTION APparatus capable of generating intense heat in pipes and confined passages for heating parts of internal combustion engines and for other uses; spark ignited; blower operated. Patented October 8th, 1918. Can be inspected at and for sale by H. W. Petrie, Limited, 131 Front St. W., Toronto.

Agent Wanted

Wanted, a jobber to represent, in Eastern Canada, an American manufacturer of well-known and advertised line of Oxy-Acetylene Welding and Cutting apparatus. Terms very favorable.

VOL. XXIV. No. 20 November 11, 1920

Making One Thousand Milling Machine Saddles

Suppose You Had to Produce One Thousand Saddles Every Year, Like the One Shown—Would You Follow the Method Suggested by the Author?—If Not, Let Us Hear How You Would Do Them

By JOHN T. WATTS

A WELL-KNOWN authority once remarked that there is no method of manufacture existent that cannot be improved upon. Commencing on this assumption, Canadian Machinery decided to give readers something entirely original by requesting certain contributors to state how they personally would produce a well known article at present being manufactured. Various parts were sent out for opinions, and the present article, dealing with the saddle of a milling machine, is both instructive and interesting. It is, of course, understood that the suggestions to follow are the author's and not ours. We take an absolutely neutral stand, merely presenting the author's views. Other material of like nature will follow in later issues, and by thus interchanging ideas mutual benefit will result. We especially wish comments and criticism regarding this series of opinions, and suggest that readers let us have their viewpoint on the present article and its productive suggestions. Here is what the author has to say:

We are to assume that the saddle shown in Fig. 1 has been laid before us to determine and design the tools, jigs, etc., and the best methods of production which will give the lowest cost of manufacture and an interchangeable product for an estimated output of one thousand parts per year.

As interchangeability is the essential point, it will be necessary to make a jig for every operation, even if the output is not increased or the cost decreased by the use of the jig.

The correct procedure for us as the

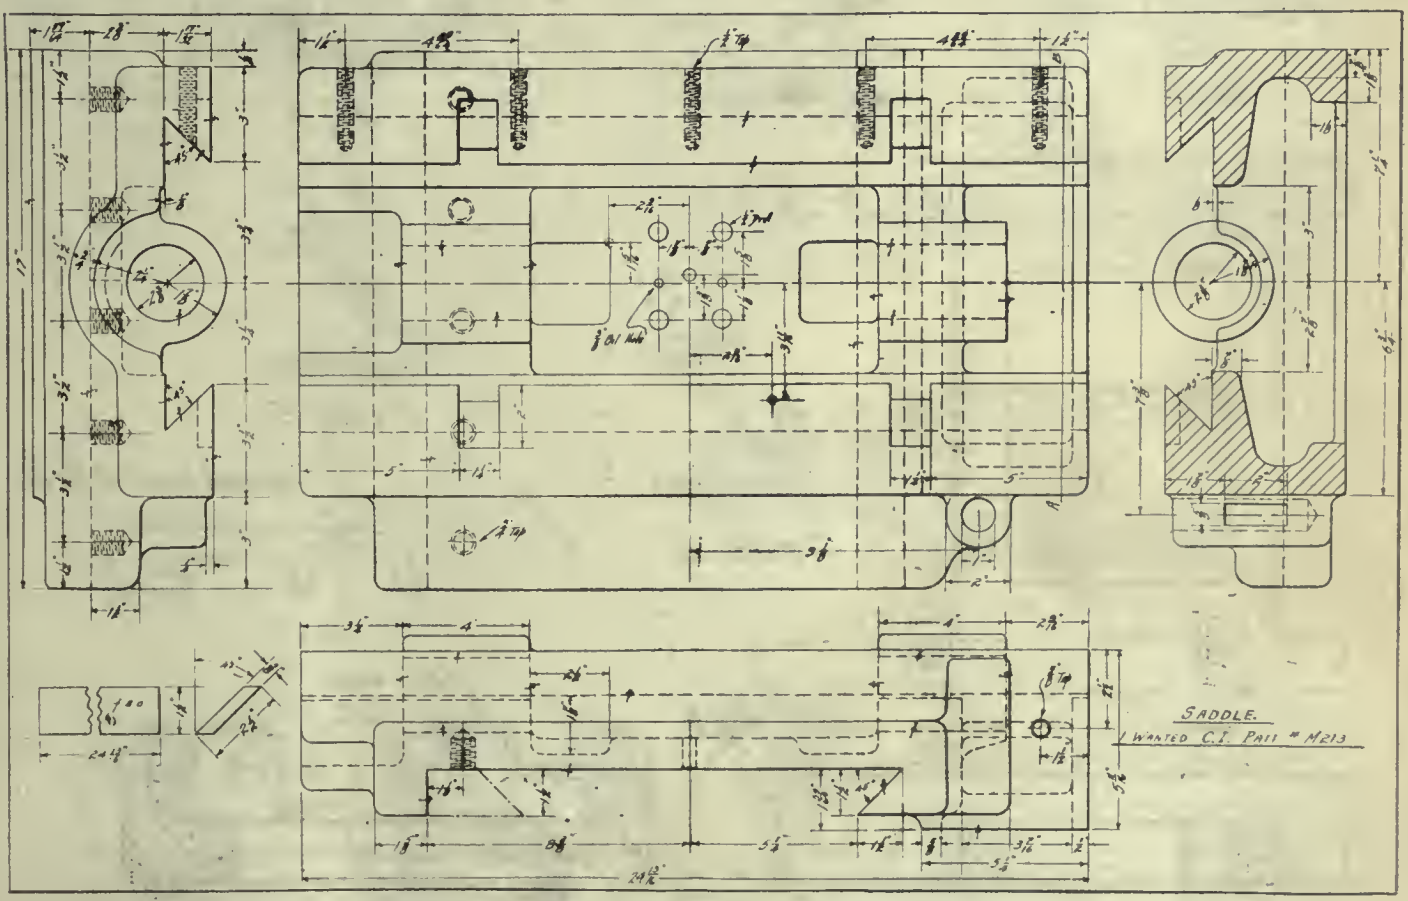

FIG. 1—THIS SHOWS IN DETAIL THE SADDLE UNDER DISCUSSION

production department is to first review the design in a general way with the idea of suggesting modifications in the shape of the part which would enable us to use standard tools or jigs which are already available and to recommend any changes which would assist us to increase production and decrease cost.

Before returning the drawing with the suggested changes to the designing department, the feasibility of carrying out the suggestions should be carefully checked and if possible a sketch made showing our idea of how the change could be made without interfering with the correct functioning of the part in question, or fouling some other part of the mechanism.

The making of this sketch will also serve to assure ourselves that we are not going to make a change that will introduce still worse troubles in some other part.

Taking the saddle before us, we decide that the most desirable way to machine the vees on the top would be by using a form milling cutter, but it looks as though the central boss would interfere, and laying out this part to scale to see just where we stand, as in Fig. 2, we find it impossible to get a milling cutter through with the boss as shown.

As the only alternative method is to plane this vee on a planer or shaper, which is slower and more expensive and more difficult to attain equal accuracy, we are justified in spending some time in an effort to eliminate this central boss.

We will suggest, then, that the design be changed to one of the following, giving the alternatives in the order of choice, that is, from a production standpoint we would prefer the first suggestion first and so on.

Suggestion No. 1. In the absence of drawings of the other parts, we assume that these bosses are only to carry the screw spindle, and possibly this function would be fulfilled as well if only one-half a bearing was used as indicated in Fig. 3.

Suggestion No. 2. In the event that it is deemed essential to have a full bearing, this could be better made a separate casting, bolted in place as shown in Fig. 4

If either of these suggestions are adopted, the vees can be machined by milling, having one cutter for roughing out and another for finishing, both taking the whole surface at once and being adjustable for wear. The accuracy, being then dependable entirely on the cutter, can be maintained easily and the operation needs only semi-skilled labor.

While suggestion No. 2 may be criticized as involving the machining of more surface than the original design, the total cost would be less, due to the greater ease with which the various operations can be performed and the fact that equal accuracy can be obtained with cheaper labor.

Suggestion No. 3. Continuing our criticism, we find that the vees are shown with sharp corners, which are a practical impossibility because the tool which produces these corners will soon wear off at the point and will then produce the shape shown in Fig. 5 and make it impossible to get a decent working fit at this point, as the fit will only be on the point and after a few days' use the slide will be a sloppy fit. Further, the edge at (a) is easily damaged, for that reason being very poor design. The vee should be changed to the shape shown in Fig. 6, for production reasons and to give a better product.

The dimension (b) in Fig. 6 can be about 1-16 of the height (c).

Experience has shown that the angle of the vees should be 55 degrees instead of 45 degrees as called for in Fig. 1, and as 55 degrees is nearly standard practice, it will be easier to get milling cutters to the 55 degree angle, and therefore it is recommended that the design be changed to give this angle.

Suggestion No. 5. The drawing does not state to what depth the tap drill for

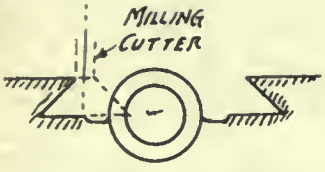

FIGURE-2

FIGURE-3.

FIGURE.4.

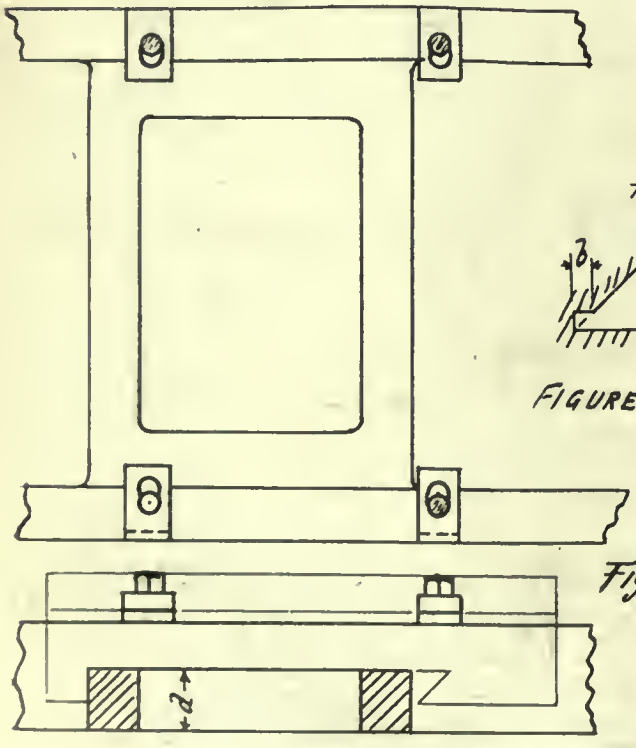

Fig 7

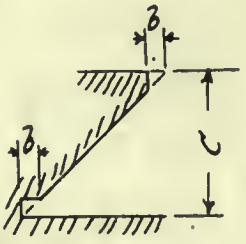

FIGURE- 6

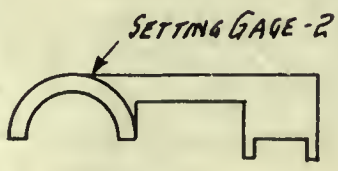
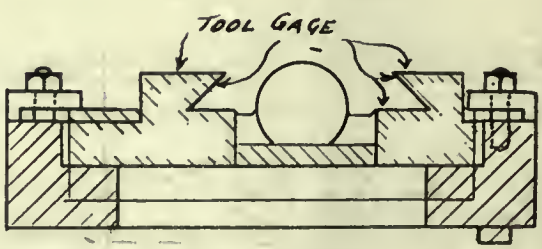
FIGURE-5





FOLLOW THE VARIOUS SUGGESTIONS CLOSELY. FIGS. 2 TO 7 INCLUSIVE

the ¾-inch tapped holes is to penetrate. This is a common omission on the part of some draftsmen and gives considerable trouble in the shop as, if the hole is not tapped deeply enough, the cap screws will bottom in the hole before taking a grip on the part they are to hold, and necessitate dismantling the machine to redrill and retap the holes. Or, as sometimes happens and is still worse, the error is not discovered until damage has been incurred to the machine.

To cover the ground thoroughly we will assume that the above suggestions have been rejected and that we are required to follow the drawing as shown in Fig. 1.

The Start

Starting with the casting as delivered to the machine shop, snagged, cleaned and wire brushed, the first point to be considered is the possibility of the casting warping from shrinkage strains during or after machining. In this particular piece, its shape is not one that would lead us to expect any trouble in this direction, provided that the casting has been allowed to season for a few weeks before work is started.

While experience is the only guide to a decision as to whether a casting is likely to warp or not, it may be stated that a casting whose length and breadth are approximately equal and the shape of which is nearly alike above and below the centre line, is not as a general rule subject to unequal cooling strains which would cause warping.

Nevertheless, the possibility of trouble in this respect should be borne in mind, and the first batch of parts run through should be carefully watched to determine the actual effect of the shrinkage strains. If the casting shows a tendency to warp, we can first try a longer period of seasoning, up to three months, which is usually sufficient to cure any warping in castings of a fairly uniform shape, and is the most economical remedy, as well as being one that tends to a better product, inasmuch as it gives assurance of a shape that will not alter after the machine is shipped out from the factory.

If the trouble still continues, we must rough machine both top and bottom surfaces and then leave the piece to season for a while before taking the finish cuts. This involves a double handling and twice setting up in the machine, and therefore, for economy, should not be used until all other means possible have been tried, even to a redesign of the part to give a more uniform shape.

When a piece is not too large the time required to season can often be very materially shortened by running the castings in the tumbling mill for a few hours. The hammering which the parts receive in the tumbling mill will frequently relieve the internal strains and so remove the cause of the warping.

Before commencing actual production, we will take one of the castings and mark it off on the surface plate, to show the location on the castings of all the finished surfaces, using the centre of the bosses for the 2⅜-inch hole as the starting point. This, because it is important that when finished the 2⅜-inch hole be central in the boss, while a little more or less metal at the other places than the drawing calls for would not be of so much importance. The lines on this casting give us the heights to the working surfaces of our jigs, with the assurance that in working to these heights we will not be taking so much or so little off one surface as to prevent cleaning up on some other surface.

The laying off of this casting also serves as a check on the pattern as to the amount of stock left for machining, and on the foundry as to the casting being true to pattern.

The upper surface seems to be the logical point at which to start the machining, and we must design a jig to hold the castings on the planer, making it to hold as many pieces as the length of the planer table will allow. The general idea of such a jig is indicated in figure 7.

As will be noted the sketch shows only one section of the jig, the idea being to simply repeat this section to fill the length of the planer table, but casting them all in one piece. The jig is made with a key on its lower surface to fit in one of the slots of the planer table as indicated, thus lining up the jig. Lugs for clamping the jig to the table should be provided, but are not shown for the reason that they would complicate the drawing unnecessarily.

The modus operandi is very simple as it is only necessary to drop the saddle into the jig, pressing the projecting part of the saddle against the cross-piece of the jig, to take the thrust of the cut, then slip the two setting gages in place and tighten up the clamps. The setting gage fits the boss on the saddle and the side of the jig and so lines up the centre line of the boss with the jig. The clamps are made with an oval hole, so that it is only necessary to slack up the clamp nuts a turn, when the clamps can be slid back and the saddle removed and the next placed.

At one end of the jig is cast a part for the tool gage, which is machined to the exact shape of the vees to be machined in this jig, but a certain fixed distance larger all over. For clarity we will suppose this distance to be 1-32-in. The tool gage is then machined so that if the planer tool in its travel is always at a distance of 1-32-in. from the surface of the tool gage it will cut the vees to the desired sizes.

The height "d" in figure 7 should be arranged to suit the finish lines on the sample casting laid off on the surface plate.

To machine, first finish the top flat surface, being careful to start the cut from the centre and feed out, to avoid the possibility of breaking off the weak corner, at the top, see "b" figure 6. Next rough out the vees, allowing not over

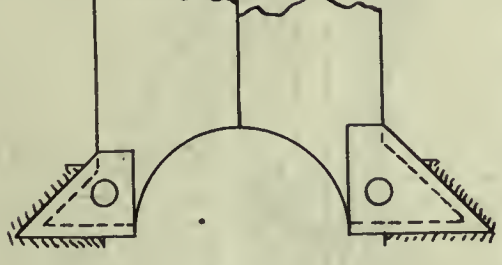


FIGURE 8

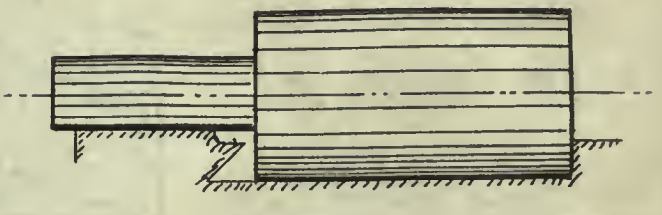

FIGURE 10

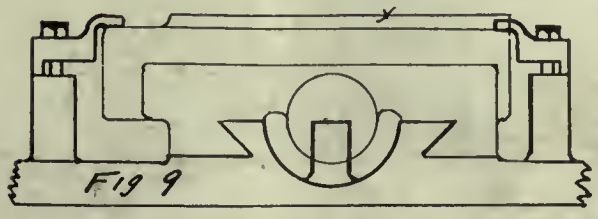

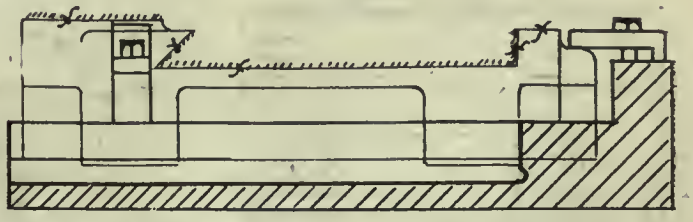

FIGS. 8, 9 AND 10—FINISHING THE VEES, AS THE AUTHOR SEES IT

1-64-in. for the finish cut. To finish the vees a form tool should be made, about as shown in figure 8. The holder would preferably be split to admit of being expanded by liners between the two halves to compensate for the wear of the tools. At first sight it might seem simpler to overcome the effect of the wear of the tool by traversing the tool sideways, but, while this is possible, much more accurate results will be obtained if the tool is cutting on both sides simultaneously, as the cut on one side counteracts the tendency of the tool to spring away from the cut on the opposite side.

The next operation will be to machine the lower slide, and a similar jig to that just described will be required, the work being done in a planer precisely as in the last operation. This jig, however, will have ways machined to fit the vees just finished in the last operation, as shown in figure 9, the saddle being pushed onto these machined ways until the central boss hits against the stop provided. The clamps are then tightened up, being similar to those already described for the fist jig.

A still better method, if the machine is available, would be to use a multi-spindle planer type miller, the jig would be the same as shown in figure 9, and the surfaces would be machined, first by a milling cutter in the horizontal spindle as indicated in figure 10, and then completed at the same setting by another milling cutter in the vertical spindle. This second cutter is illustrated in figure II. Doing the work in this way accuracy is easily attained by the use of stops fitted to the feed mechanism.

Boring the 2 3-8-in. Hole

The 2 3-8-in. hole is to be bored next and we must design a jig to do this job in a drill press. The jig must of necessity be made to fit the upper vees, bebecause these were set by the jig to be central with the boss, when being planed. The boring jig is shown in figure 12, the boring tool indicated being of the adjustable multiple type, which can be made or purchased on the market.

The upper guide being hinged can be swung out of the way, and a saddle placed on the jig. A loose bushing is used in the top guide while the first cutter or drill is passing through the top hole, when the top hole is drilled. This bush is removed and the reaming of the top hole completed. The boring bar is then traversed down and the machining of the bottom hole completed. The bottom guide also is fitted with a loose bush which is pushed out by the drill, the drill then fits the guide and holds the bar central until the bottom hole is reamed.

The next operation is to face the bosses, which, the top guide being swung out of the way, can be easily accomplished with a standard spot facing tool substituted for the boring bar in the drill

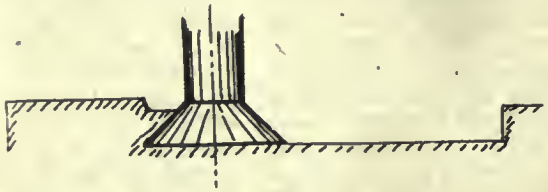

FIGURE 11

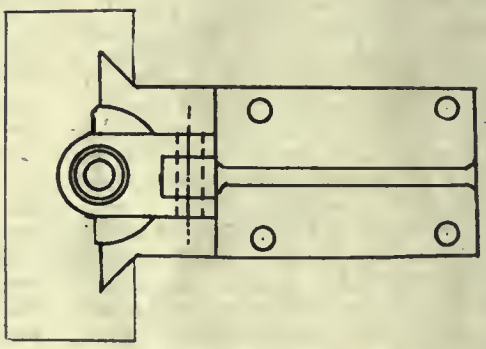

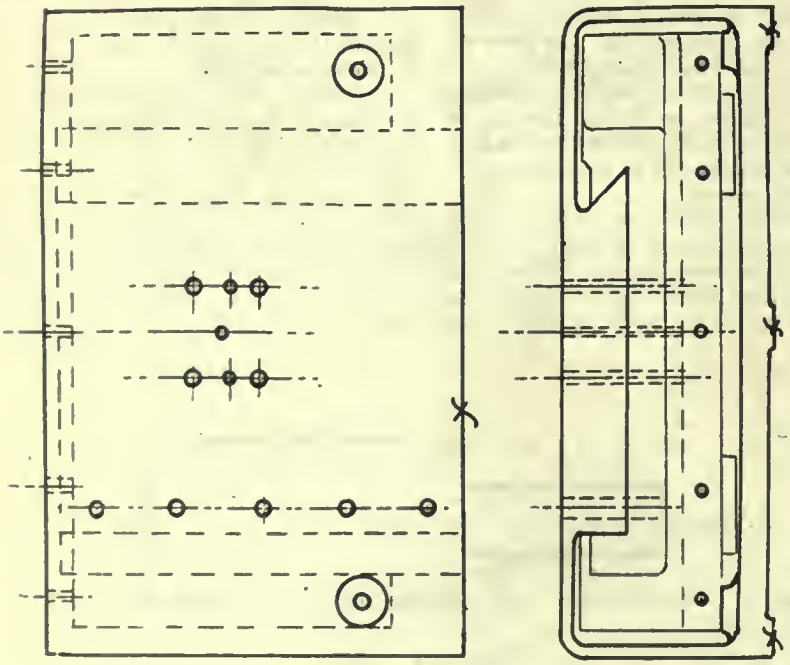

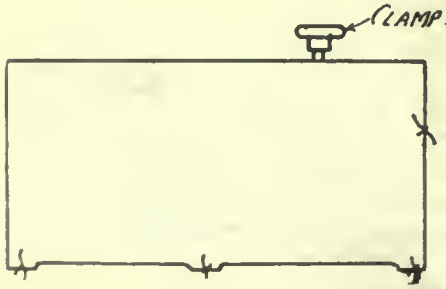

Fig 14

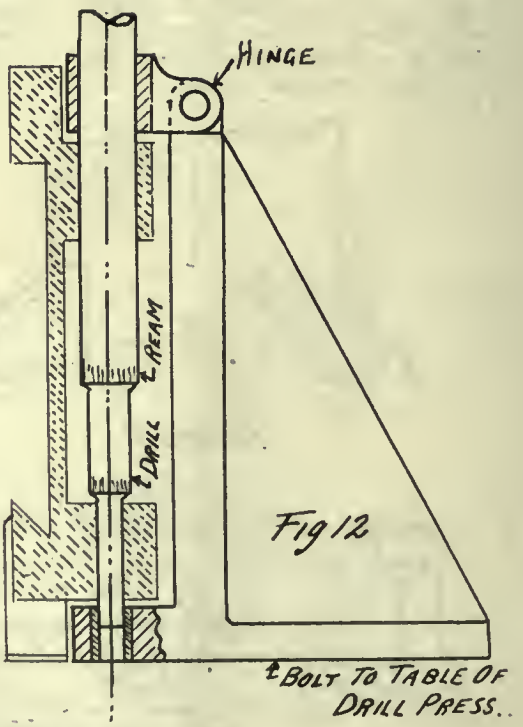

Fig 12

THE REMAINING STEPS IN THE SADDLE'S COMPLETION.

press chuck. The correct location of these faces can be got by marks or stops on the drill press spindle.

The final operation is to drill the small holes, and for those we chose a box type of jig, which will permit drilling all the holes with the one jig. This jig is shown in figure 14, and a study of the drawing will show that the saddle is slid into the jig and tightened by two clamp screws, the casting is located by a part of the jig which fits the lower vees. After drilling the holes on one side, the jig is turned over ninety degrees and the remainder of the holes drilled.

Having laid out the jigs it remains to determine how many machines it will be necessary to have to get the desired output, as it may be that we will have to have more than one of each kind of jig.

Taking up each operation in the order in which they are executed, we have first the planing of the upper vees. The area of the surface to be machined is 24 13-16-in.x15-16-in. or 374 square inches.

Allowing that we can plane 160 square inches per hour, on this type of work, the operation will require 2.4 hours per piece. Bear in mind that in estimating the time required to execute these operations, we should not base our estimate on record outputs made on similar parts, but on the average actual output that we can safely figure on over a whole year allowing for all the accidents, stoppages and other delays that are sure to occur during the course of a year.

Taking 300 working days per year and eight hours per day, gives us 2,400 working hours per year, or exactly the required output of 1,000 per year at the rate of 2.4 hours each. As there should be no difficulty in accomplishing the operation in this time, we may allow that one jig will be sufficient.

The second operation, planing the lower vees, which have a surface to be finished of 17-in. x 24-in., or 408 square inches, will require, at the rate of 160 square inches per hour, 2.5 hours. This is 2,500 hours for the yearly output, and will require two jigs to make sure of getting the output.

The third operation, boring the 2 3-8-inch holes and facing off the bosses will consume about four hours, or a total of 4,000 hours per year. This indicates that we require to make up two jigs.

The drilling and tapping of the small holes should be accomplished at the rate of approximately four per hour, and the one jig will be ample for this operation.

Generally the management will ask for an estimate of the cost of the jigs before issuing instructions to proceed with their manufacture, and the simplest and most accurate way of arriving at this cost is to have a record of the costs of all jigs that are made, with their weight in an accessible form. From this record we take the cost of jig most similar to the one to be estimated on and taking its cost per pound, we can, by calculating the weight of the proposed new jig, and multiplying this weight by the cost per pound arrive at a very close approximation to the actual cost.

Taking up the four jigs, designed for this saddle, we estimate the costs to be as follows: No. 1, $660.00; No. 2, $750.00; No. 3, $200.00; No. 4, $200.00; total $1.810.00

This is a cost of $1.81 for each saddle, assuming that one year will be the life of the jig. Of course its useful life should be much longer than this, but changes in design, or in demand for the product may occur and a year is long enough to calculate on to be on the safe side.

The saving effected by the use of the jigs will, at the lowest calculation, be the saving made by using semi-skilled labor, instead of the highly skilled labor which would be necessary if the jigs were not available.

Assuming that skilled labor would execute the work in the same time without jigs that we have allowed for the semi-skilled labor with the jigs, that is a total time of 9.15 hours per saddle, the saving per piece will be the difference between the rates for that length of time of the two classes of men. Taking this difference at 30 cents per hour, the saving will be 30x9.15, or $2.75 per saddle, to be credited against the cost of $1.81 per saddle for the jigs.

Evidently then, even without crediting the jigs with the value of the assurance of interchangeability of their product, they will pay for themselves in less than one year.

Using New Metals.—A very significant hint was thrown out by the chairman of the Institute of Metals at a recent convention of that body. He pointed out that while the internal combustion engines used to drive merchant ships contained only 3 per cent. of metals other than iron and steel, the driving equipment of the latest British submarines (oil engines, steam turbines, and electrical machinery combined) showed a proportion as high as 37 per cent. Therefore the marine engineer would find in naval practice suggestions for increasing power and reducing weight by using some of the wonderfully strong yet light alloys which British metallurgists had developed.

13. How to increase production, yet lower operating cost.
14. Something that pays you well.

NOTE.—Readers are sending in as many as four names to the one question. This is hardly fair to the other chap who sends in only one, so that in future, two suggestions only are allowed per question. Another rule will be that no answers will be considered later than three weeks from date of publication. Always specify the date of issue and write your answers on separate sheet of paper. There is no need to write the queries over, merely say query No. 1 and so on.

The Engines Used in Early Railroad Practice

Continuing Our Story of Last Week on Transportation We See Herein a Few More Examples of the Early Type—In a Later Issue the Modern Locomotive Will Be Discussed

By J. SNOWDEN BELL

MR. A. MEHAFFEY, superintendent of motive power of the Allegheny Portage Railroad division of the line, to which the British engines had probably been transferred, goes much further than Mr. Gay in reporting unfavorably on them. In a report of November 1, 1836, he says: "Two of them, viz., the 'John Bull' and 'Red Rover,' both British engines, have recently been sold, and it would have been a saving to the Commonwealth had they been given away for nothing the first day they were placed on the track."

Data on English Engines

This statement savors so strongly of prejudice as not to be worthy of credence, and the temperate and reasonable criticism of Mr. Gay correctly indicates the reason for the failure of the British engines to give satisfactory results in service. As they were not equipped with trucks, it is obvious that they were not well adapted to traverse the short curves of the line, as also their comparatively light construction, noted by Mr. Gay, impaired their hauling capacity. It does not, however, by any means, necessarily follow that they were either worthless or could not have been used, with reasonable advantage, in lighter service.

The five British engines, which are stated, in Mr. Mehaffey's report, as being the "Albion," "Atlantic," "John Bull," "Fire Fly" and "Red Rover," were built by Robert Stephenson, of Darlington, England, and were all four-wheeled machines, having one pair of driving wheels and one pair of carrying wheels, which were journalled in pedestals rigid with the main frame, and consequently had no capacity of relative radial or lateral motion. Messrs. Robert Stephenson & Co., Ltd., of Darlington, England, have furnished a drawing entitled "Steam Engine No. 54" (builder's number) and a more complete blue print, "Working Drawing of Nos. 110, 112, 113 Locomotives, March 24th, 1835; Nos. 129, 139, March 4th, 1836," together with tables of dimensions of "Locomotives supplied to the United States Railways," and the writer has also received from an English correspondent a copy of a list headed "Locomotives built by Robt. Stephenson & Co. for the U. S. A. between 1831-1836," purporting to be made up from Wishaw's Railways of Great Britain and Ireland, 1st Ed., 1840, Tables 27 and 28, Sec. 2.

From the above data it would appear that in three of the five locomotives built for the Philadelphia & Columbia R. R., the driving and carrying wheels were of the same diameter, and in the other two the driving wheels were of greater diameter than the carrying wheels. The engines of these two wheel arrangements are not, however, indicated by name in the lists.

Fig. 9 is a reduced reproduction of the builder's blue print showing the engines having driving and carrying wheels of different diameters, the dimensions of one of the engines being given as follows: Light weight, 8 tons, 11 cwt.; cylinders, 12 x 8 inches; driving wheels, 5 feet diameter; carrying wheels, 3 feet 6 inches; boiler, 3 feet 4 inches diameter, 8 feet long; firebox, 2 feet 5 inches x 3 feet 2½ inches x 3 feet 5¼ inches; height of chimney above rail, 14 feet 6 inches. These dimensions are not, however, entirely in accord with those appearing in the list from Wishaw's book, in which the cylinders are stated to be 10 x 16 inches. The cylinders of the engines having driving and carrying wheels of equal diameters (4 feet 6 inches) were 10 x 16 inches.

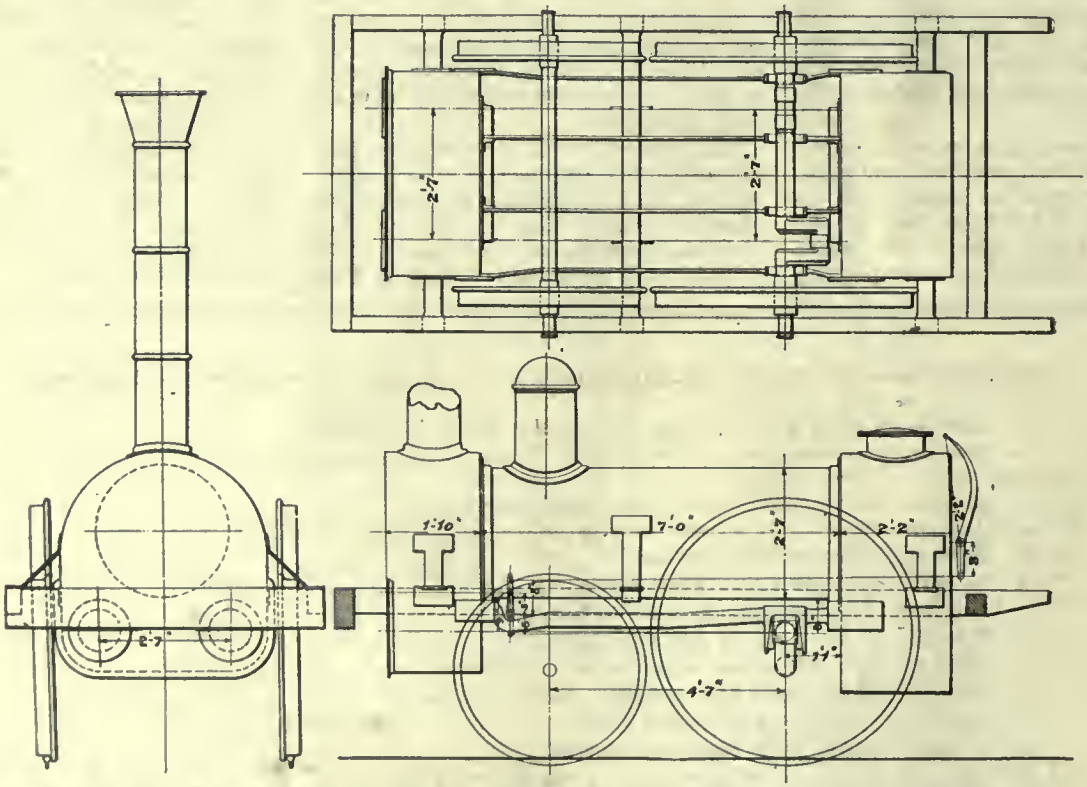

FIG. 9 A REDUCED REPRODUCTION OF THE BUILDER'S BLUE PRINT. SEE TEXT FOR FURTHER DATA

The principal engineer's report of October 30, 1835, states, as before noted, that among the seventeen locomotives then in service there was one that was built by Coleman Sellers & Sons, and Mr. Mehaffey's report of November 1, 1836, specifies two, the "America" and

"Sampson," as built by C. Sellers & Sons, and first run September 1, 1836. The only data that have been obtained regarding these engines is that contained in a letter from Mr. Charles Sellers to his brother, Mr. George Escol Sellers, dated July 23, 1884, and a rather crude wood-cut of a locomotive appearing in an advertisement of Coleman Sellers & Sons, Cardington Iron Works, which is here reproduced as Fig. 10.

The following excerpt from Mr. Sellers' letter contains all that he says which is descriptive of the locomotive:

"Our first locomotive was put on the railroad in 1835. I ran it for one week before we asked the commissioners to take a trial trip to Lancaster and back. It was outside connection, centre-bearing on the truck and iron frame. I recollect great objection was made to the iron frame, as it would not give to the inequalities of the road; all of the English locomotives, and I think two of Baldwin's on the Pennsylvania Railroad, were wooden frames.

"They (the commissioners) said that we had to pay Baldwin $500 for a patent attachment to throw part of the weight of the tender on the driving wheels, which we did not use, but that we had put on a patent attachment of our own to throw part of the weight of the forward end of the engine on the drivers, which they thought was much better, as it was self-acting. The drawing for the engine most have been made in 1835 (I think earlier, because we had to get the boilers made in New York, and very poorly made at that)."

The traction increaser referred to in this letter was doubtless that of the patent of C. & G. E. Sellers, May 22, 1835. The principle of the invention is stated to be: "So coupling or connecting the cars containing the load to be drawn to the body of the locomotive engine, as that the load by its action upon a lever or standard shall tend to raise the fore end of the locomotive in any desired degree, and thus to loosen the pressure upon the fore, and transfer the same to the hind wheels." The appliance is very crudely shown and described, and it is not at all clear how the tender or train is to be connected to it, but, if operative, it must have been, as stated in the letter of Mr. Sellers, "self-acting."

The early motive power of the state system also included a locomotive built by Long & Norris, the "William Penn," stated in Mr. Mehaffey's report as having been first run October 14, 1835, and a number of locomotives of the same type, built by William Norris, among which were the "George Washington," "Robert Morris," "Benjamin Franklin," and "Washington County Farmer," which are stated, in the same report, to have been put in service at different dates in the year 1836.

All the locomotives built for the state by William Norris and his successors up to the year 1840, or thereabouts, were of the 4-2-0 type, and were, in all essential particulars, similar to that shown in Fig. 11, which represents one of a lot of seventeen constructed by him for the Birmingham & Gloucester Railway, England. They did not materially vary in dimensions from the "William Penn," the weight of which was 23,560 pounds, of which 14,600 pounds were on the driving wheels; cylinders, 10 x 20 inches; driving wheels, 4 feet diameter; boiler, about 14 feet long and 36 inches diameter; grate area, about 9 square feet.

Respective Merits

The merits of the respective locations of the driving axle in the Baldwin and the Norris engines, i.e., behind the firebox in the former and in front of it in the latter, were often the subject of discussion during the period that the 4-2-0 type continued to be practically the only one in service. Those who favored the Baldwin arrangement correctly maintained that it gave the engine a longer wheel base and thereby rendered it steadier at high speeds, while the advocates of the Norris design, with equal correctness, pointed out that it increased the adhesion and tractive power of the engine. The advent of the 4-4-0 type rendered the question an academic one, and meanwhile, on the lines of the state system, the Baldwin engines were generally preferred for passenger service and the Norris engines for freight. Both classes undoubtedly gave as efficient service as was possible with their limited capacity, and the reports of the performance of the Norris engines were uniformly favorable. Indeed, the report of J. W. Patton, superintendent of the Allegheny Portage Railroad, October 31, 1838, went so far as to make the statement (which would seem to be of doubtful correctness), that "of the locomotives now on this road those made by Mr. William Norris, of Philadelphia, are much superior, doing double the amount of work, with half the quantity of oil and fuel, and not requiring half as much repairs."

All the motive power thus far referred to was constructed in Philadelphia and first put in service on the Philadelphia & Columbia Railroad division of the line, although some of the locomotives were, from time to time, transferred to the Allegheny Portage Railroad and their places supplied by new ones. For some reason, which is not apparent, the canal commissioners placed their orders for locomotives intended for service on the Portage road, in other cities, and on the opening of the road for traffic, in the season of 1835, three locomotives were ready for service on the long level between inclined planes 1 and 2, these being the "Boston," "Delaware," and "Allegheny." The following matter relating to these three engines is taken from the extremely interesting "History of the Pennsylvania Railroad," by William Bender Wilson, Philadelphia, 1899 (Vol. I, pp. 121-123):

"The 'Boston' was the first locomotive to do service on the Allegheny Portage Railroad. It was built by the Mill Dam Foundry Company, of Boston, Mass., and delivered at Johnstown just before the close of navigation in 1834. It was put in condition during the winter and sent to Pittsburgh to be used as a pattern. It was returned to Johnstown, March 28, 1835. Without water or fuel it weighed 8½ tons. Its cost, exclusive of tender, on the wharf at Boston, was $6,996.75. The cost of transportation to the railroad amounted to $223.25. It was put into regular service May 10th, and until November 1, 1835, made its regular trips, covering 52 miles daily, with the exception of 2½ days, when it was laid off for repairs, which cost $17. Engineer Welch, in reporting upon its services in the time mentioned, said of it: 'This engine during the greatest part of the season, in connection with its other work, has hauled the passenger cars in both directions each day. This detained it; otherwise it might have made three trips a day for the greater part of the time. It performed the labor every day of eighteen horses, and it might do easily one-third more if it were not necessary to reserve it for the

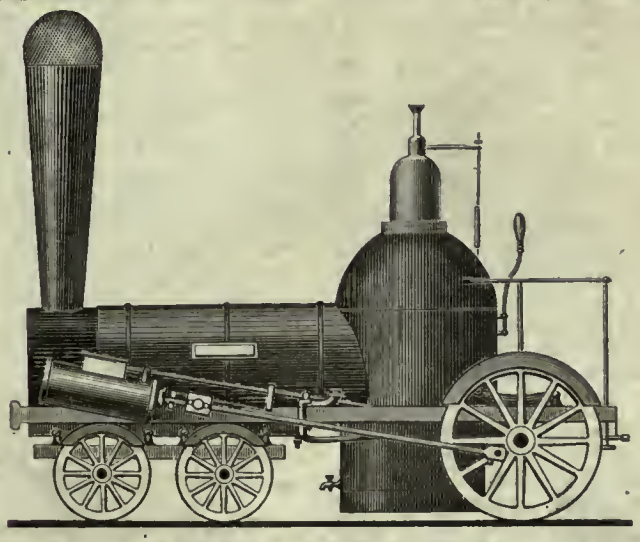

FIG. 10—THIS TYPE OF ENGINE WAS PUT ON THE ROAD ABOUT 1835

transportation of passengers. The daily expenses of running it are $7.12½, exclusive of repairs.' Its cylinders were 8 inches in diameter, with a 16-inch stroke, whilst its driving wheels were a small pair, 4 feet in diameter, with wooden felloes and spokes. The wheels were tired with iron and were flangeless. During the season of 1835 it was in service 174 days, averaging 52 miles a day distance, and 10 miles per hour speed. Its steam pressure was 125 pounds to the square inch.

A Different Story

"The 'Delaware' and 'Allegheny' were not so satisfactory, and were a source of expense and vexation during the season. They were built by Edward A. G. Young, of New Castle, Del.; reached Hollidaysburg, April 15, 1835, and were sent to Johnstown where the parts were fitted together and the necessary alterations made in an ordinary blacksmith shop, there being no machine shop in operation at the time. Their contract price was $5,500 each, and it cost $158 additional per locomotive to transport them from Philadelphia to Hollidaysburg. Better results were expected of them than from the 'Boston' because the boilers were larger and would generate more steam. The machinery was arranged differently from that of most other engines built upon the same general principles. It was apparently more simple, but less substantial. The builder had had several years' experience in the use of locomotive engines, and it was expected that the deviations made by him from the general plan, and from the engine designated in the contract as the model according to which he was to build for the Portage Railroad, would be an improvement inasmuch as they were to be put up and tried upon the railroad by persons furnished by the builders and approved of by the engineers before they were finally paid for.

"The 'Delaware,' after running for four days, broke its crank axle, and had to remain idle until the 1st of September before it was repaired by the contractor. The 'Allegheny,' after considerable refitting, was accepted. It ran about two weeks when its crank axle broke, rendering it useless for the balance of the year. These three locomotives performed all the service they did for the year on the 13-mile level. The 'Pittsburgh,' built upon the plan of the 'Boston,' was constructed by McClurg, Wade & Co., at Pittsburgh, at a cost of $4,500, and was delivered on the road on September 3, 1835."

On page 127 of the same volume there is given the following description of the performance of a locomotive which had been ordered for the Philadelphia & Columbia Railroad, and was tested on its way thereto on the Portage road:

"It was during this year (1836) that a question of what power should be used on the Hollidaysburg level, that had been agitated for some time, was settled. As the steepest grade on that level was fifty-two feet to the mile there was a great diversity of opinion as to the ability of a locomotive engine to work on the level. The authorities had contracted March 24, 1836, with McClurg, Wade & Co., of Pittsburgh, for the construction of a locomotive named the 'Backwoodsman,' for use on the Columbia & Philadelphia Railroad, and as that machine was ready for delivery, the board of Canal Commissioners ordered that it be delayed en route to be experimented with on the level.

"Arriving there in the latter part of September, it was worked under the charge of Messrs. Bridges and Whitney for several days, and proved that locomotives could be used with ease and economy there. At the first trial it arrived at the Hollidaysburg scales from the foot of plane 10 in eleven minutes, hauling eight heavy bloom cars. Its next trip, with thirteen heavily laden cars, occupied twelve minutes."

The report of J. Snodgrass, superintendent of motive power of the Allegheny Portage Railroad, who took charge February 15, 1839, states that there were then seventeen locomotives on that road, the largest portion of which had been used on the Columbia road previous to 1835. These included nine built by William Norris; one, the "Boston," by R. M. Houton; three, the "Allegheny," "Delaware" and "Comet." by E. A. G. Young; and four, the "Backwoodsman," "Mountaineer," "Conemaugh" and "Pittsburgh," by McClurg, Wade & Co., of Pittsburgh, Pa.

Development of the inefficient and wasteful management, and demoralizing results of improper exertion of political influences, which, in the view of the writer, are characteristic of government ownership, began almost upon the inception of the operation of the main line of the Public Works of Pennsylvania thereunder. A recital of details would be foreign to the purpose, and beyond the permissible compass of the present paper, but an instance is presented in the explosion of the boiler of the engine "Bush Hill," on the Allegheny Portage Railroad, April 23, 1847, a report of which was made June 10, 1847, to the Committee of Science and Arts of the Franklin Institute, Philadelphia, by Mr. Edward Miller, a civil engineer of the Pennsylvania Railroad. This report is published in the "Journal of the Franklin Institute," whole No. Vol. XLIV, 1847 (pp. 69-71), and being believed to be specially interesting, it is here reproduced in full, attention being particularly called to the italics, which are those of Mr. Miller, and to his concluding paragraph:

Details of the Accident

"John C. Cresson, Esq.,

"Chairman of Committee on Science and the Arts, Franklin Institute.

"Dear Sir:—Upon the day I passed over the Allegheny Portage Railroad, April 23rd, 1847, one of the locomotive engines attached to a freight train exploded, killing the engine driver and injuring severely two other persons. I could not, at the time, obtain a correct statement of the facts, as business required me to proceed the same night to Pittsburgh. Being at Johnstown on the 4th inst., I had an opportunity of examining the wreck and enquiring into the facts connected with the explosion, which I now send you, to be laid before your committee, if you consider them of sufficient importance

"The locomotive 'Bush Hill' was built by Messrs. Norris, and put on the Columbia Railroad April 17th, 1837. In the fall of the same year it was transferred to the Portage, where it has since been in constant use. It was a six-wheeled engine, weighing 12 tons, being one of the heaviest on the road, used the adhesion of two wheels, and was considered one of the best machines on the Portage. It was generally used as a freight engine, but had been running on the 13-mile level for some days prior to the morning of the accident, with the passenger train.

"On that day the steam was raised by the fireman before breakfast, with the expectation that the 'Bush Hill' would have to take the passenger train; but the regular passenger engine, which had been undergoing repairs in the Johnstown shops, arrived and took its place. But for this change the loss of life might have been much greater.

"The fireman, John B. Davis, states that he tried the gauge-cocks before going to his breakfast, and found the water above the upper cock. He also tried them after breakfast, before the engine started, and found a full head of water.

"The engineer of the 'Bush Hill,' James Patterson, had gone down to Johnstown the night before to ask that another person might be sent to run his engine, as he wished to attend a funeral. James Barron was accordingly sent up with him by the passenger line in the morning to Incline Plane No. 1; but, as the funeral was to take place at the halfway house, it was concluded that Patterson should run the engine that far, Barron accompanying him. The 'Bush Hill' was attached to a freight train, and after proceeding about one-quarter of a mile exploded, killing Patterson and wounding Barron and Davis badly.

"The only part of the boiler which gave way was the forward flue-sheet, the upper part of which was torn from the flanch by which it was riveted to the boiler, as far down as the upper row of copper flues, which was also torn loose. The remaining flues, and the whole cylindrical part of the boiler, together with the dome and fire-box, sustained no injury from the explosion. The rent followed strictly the angle of the flanch without starting a rivet. The rush of steam forward threw the engine entirely over, and it fell backward, bending the platform against the dome, and

crushing the tender and one of the cars. The working gear was much bent and broken.

"The flue-sheet was made of two plates riveted together; the lower one, through which the flues passed, being of three-eighths of an inch iron, and the upper, one-quarter inch. The upper plate was strengthened originally by two stay-bars, both of which were broken off, their fractures showing that they had given way long before. No signs of want of water, nor of overheating, appeared in the flues, fire-box, or any part of the boiler.

"The angle of the flanch of the flue-sheet where the rent occurred was probably injured originally in the bending, as a very bad flaw extends not only around the fractured part, but also around the portion below the flues, which was not injured by the explosion. I have sent two portions of the flanch by Mr. Power to the Institute, from which this will be apparent.

"Mr. James Bowstad, the foreman of the Johnston shops, says *he noticed last winter that the flue-sheets of several of the locomotives, including the 'Bush Hill,' were sprung*, and he believes that in all these cases the stay-bars are broken. The other engines which are in this condition are in daily use on the road, and they are unable to repair them, because there are no spare engines to supply their place. He considered 'Bush Hill' in good order in all other respects. He says that he examined it the day before the accident in order to ascertain whether a new patch which had been put on the dome leaked. The steam was then high, but it did not leak of any consequence. James Barron states that when he and Patterson got on the engine the steam was escaping rapidly from this patch, and he thought it too high, for *it was very blue*. He did not, however, at the time, consider it dangerous. Neither Barron nor Davis knew anything about the condition of the safety-valve, and they have no recollection of hearing the steam blowing off at the valve.

"Mr. Power, the superintendent of the road, believes that the valve was screwed down by somebody while the fireman was at breakfast, during which time the engine stood on the track, fired up and waiting for the train, with nobody to look after it. This is, however, mere surmise; the injury to the valve preventing any conclusions as to its condition. The safety-valve was two inches in diameter, and the scale of the spring-balance would not indicate a greater pressure than 130 pounds to the square inch if screwed down as far as it would go.

"In conclusion I will remark that the cause of this accident is more manifest than in any explosion I have had occasion to investigate; the evident flaw at the flanch of the flue-sheet, and the fracture of the stay-bars rendering an explosion almost inevitable, if any accident or carelessness should produce an unusual head of steam.

"What can be said of the policy which compels the use of locomotives in such a condition as this? for there is good reason to believe that several others are in the same dangerous state. The number of these machines on the Portage is entirely insufficient to convey the traffic upon it with economy and safety; all of them have been many years in use, and many of them are engines which had been used on the Columbia road until antiquated before being transferred to the Portage.

"Very respectfully,
"Edward Miller, C.E.
"Pittsburgh, Pa., June 10th, 1847."

A resolution of the board of Canal Commissioners, dated June 2nd, 1838. directed that two engines be fitted to the use of anthracite coal as soon as practicable, pursuant to which a series of experiments was commenced, which were stated by A. Mchaffey, superintendent, Philadelphia & Columbia Railroad, in his report of that year, to have "produced the most gratifying result." The plan first tested was "to attach a fan to the front of the boiler of one of the locomotives, and thus create a draft. This, together with some trifling alterations in the engines, promised, in theory, to answer a good end, but when brought into practice was found insufficient to keep up the fire at all times and under all circumstances, as the fan could be put in requisition only when the locomotive itself was in motion." This having failed, the master mechanic, Mr. Brandt, suggested placing a fan of a different construction, immediately in front of the ash pan, and driving it by a separate engine. An application of this arrangement was accordingly made, the engine having a cylinder of a 4-inch bore and 8-inch stroke and being placed on the left side of the boiler.

The performance of the locomotive thus equipped was, according to the report, very satisfactory, stress being laid upon the fact that the blower was available whether the locomotive was standing or moving. The report makes the following statement as to the performance of the locomotive, the name or builder of which is not, however, mentioned:

"The quantity of coal consumed from one plane to the other (distance 77 miles) with a train of twenty or twenty-five loaded cars, is about one and a half tons, at four and a half dollars per ton, retail price. A train of the same weight would require two cords of oak wood, the average price for which, cut and split ready for the engine, is four and a half dollars a cord, thus showing a gain in favor of the coal, thirty-three per cent. Besides, coal enough can be loaded on the tank at Columbia, to carry the train to Philadelphia, without the loss of time and cost of labor, consequent upon stopping and loading wood about every twelve miles.

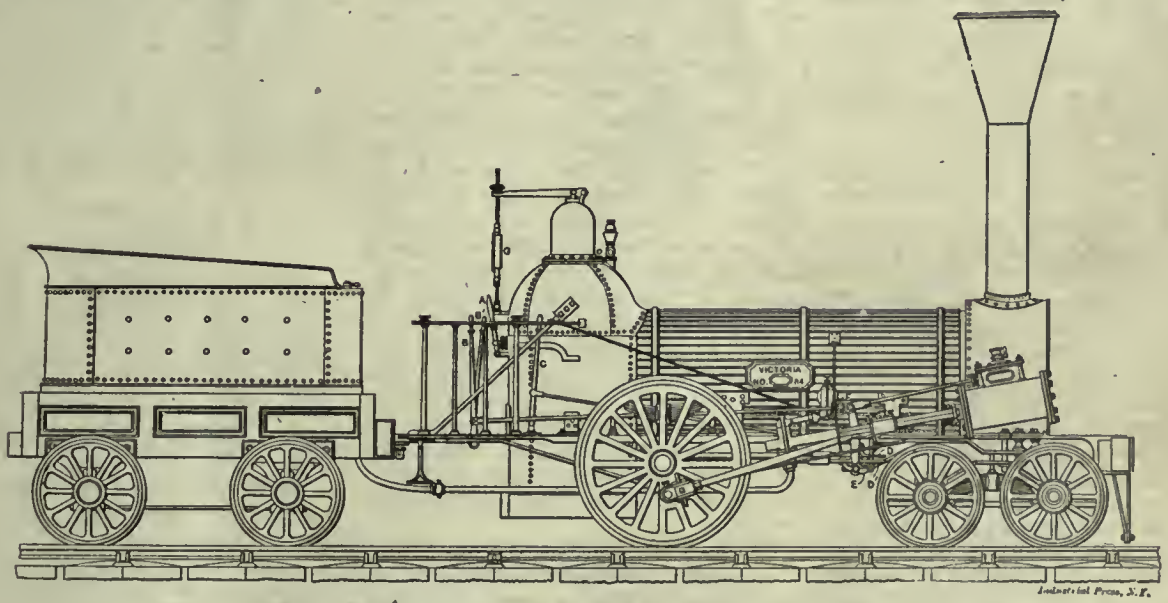

FIG. 11—THE TYPE BUILT BY WILLIAM NORRIS AND SUCCESSORS

"The locomotive above described is now performing her regular work from day to day. Another on the same plan will be ready in the course of ten days." The Canal Commissioners' report of October 31, 1839, contains that of James Cannon, then superintendent of motive power, in which he mentions the purchase of three locomotives, built by Henry R. Campbell, of Philadelphia, costing, with tenders, $7,500 each, of which he says that they "are machines of the very highest order. They weigh thirteen tons and combine great strength and power with beautiful finish. Their performance has fully equalled all my anticipations." He also refers favorably to two locomotives built by D. H. Dotterer & Co., of Reading, and to the purchase of an engine with vertical boiler, which had been placed on the road nearly a year before by Ross Winans, a similar engine being daily expected. He then refers to the experiment made by "the late superintendent" (Mr. Mehaffey), in the burning of anthracite coal, as to which he says that it "did not succeed and was abandoned before the undersigned took charge of the road." He then describes the plan in use under his supervision as follows:

"The plan now in use is a very small rotary attached to the bottom of the boiler which is driven by a small quantity of steam taken from the dome. The fan is enclosed in an iron casing from which the air is conducted through a funnel to a perfectly tight iron chest, which encloses the whole of the ash pan. The air being forced into the chest, it is constantly working itself through the fire by the power of its own pressure and thereby keeps up a constant blaze, and an amount of heat equal to all its purposes. This fixture was first tried upon a new engine called the 'James Clarke,' one of Mr. Baldwin's first-class machines. It has been making its regular trips for about six weeks, and as yet has given no sign of a failure. It has drawn very heavy loads at every trip and has done its work with more apparent ease than when wood was used upon it as a fuel. As a test, the coal was weighed one trip. The engine drew twenty-two loaded cars, or one hundred and twenty-one tons, and consumed one ton and a half of coal, and had it been of the purest quality and well selected, the trip could have been made with a ton and a quarter, costing about seven dollars and twenty-five cents, while the same amount of freight, drawn by the same engine, would have required two cords of wood, which, including cording, cutting and splitting, costs about eleven dollars. This coal is from the Pottsville mines, and it is the only anthracite which we have yet found to answer the purpose. I may also state that there is other coal of a similar quality, as convenient or more so, that will probably answer as well upon trial.

"There are now five engines upon the road which are propelled by steam, generated with anthracite exclusively, and it is believed that by the first of January all the heavy engines on the road will be ready to use it.

"Numerous experiments have also been made in the use of bituminous coal. This, when it can be had of a pure quality free from sulphur and in masses large enough to prevent its falling through the grates, has been found to answer admirably by a very simple alteration of the grate bars. Four engines are now using it exclusively. Two are employed in drawing the day lines of passenger cars, and two on the night lines of passenger and freight cars."

In the annual report of the commissioners, January 15, 1841, Mr. Cameron says that the engine contracted for with Ross Winans is similar in principle to the previous engine, but entirely different in its proportions, and adds: "It is intended exclusively for the transportation of heavy trains of burthen cars. It will haul double the ordinary train, but, owing to its great weight, must be run very slowly over the road."

Prior to the above experiments on the Columbia Railroad, anthracite coal is stated to have been burned successfully on the Baltimore & Ohio Railroad, in the "grasshopper" and "crab" engines of Ross Winans, with vertical boilers, the fire-boxes of which did not have a greater area than those of the engines of the Columbia road. In the Winans engines, the fan was operated by a rotary engine worked by the exhaust steam so that they were subject to the objection, noted in Mr. Mehaffey's report, of being inoperative when the engine was standing, although this does not appear to have impaired their performance. In view of the successful results in burning anthracite coal, reported by the two superintendents of motive power of the Columbia road, it is remarkable that the use of this fuel was not continued, but this does not appear to have been done.

The substitution of a motor-operated fan for an exhaust blast, as a means for creating the necessary draft in a locomotive fire-box, which had been practised prior to the year 1834, has latterly been the subject of consideration by engineers of acknowledged ability in the design of locomotives, and a number of designs for the application of the principle have been proposed. So far as the writer has been able to ascertain, none of these has gone into actual service, but the principle appears to be a correct one, and results of practical value may reasonably be expected from its development.

The haulage of the sectional boats constituted a considerable portion of the service of all the locomotives which have been referred to, and while such haulage also formed part of the service of the larger and more powerful locomotives which superseded them, it was not continued for a very long period in the later engines. The consideration of the original and following early motive power which has been herein presented, would, therefore, seem to be sufficient in connection with the general subject—sectional boats.

The importance and value of inland navigation upon canals and canalized or deepened rivers has for a long time been fully recognized, and large expenditures, both governmental and private, have been devoted to its development. Economical considerations have determined that the dimensions of vessels most desirably adaptable for service in such navigation, should be such that they would not be capable of haulage over railroad track. It is, consequently, while not impossible, altogether improbable that the system originated in the United States of transferring freight without breaking bulk over a line of alternate links of railroad and canal, will be reproduced in the future. Nevertheless, it is not too much to say that Canvass White's conception, nearly a century ago, of such a system, rises to the level of engineering genius, and the practical development of that conception into successful operation by his successors, the leading features of which, so far as information was obtainable, the writer has endeavored to present, evidence those who participated in it to have been sufficiently able and ingenious mechanics, and energetic operators, to merit that a record of their achievements should not be omitted from the pages of historical technical literature.

NEW CATALOGUE

The Saint Louis Machine Tool Co., St. Louis, Mo., have issued a new catalogue dealing with their line of machine tools. This catalogue is known as No. 16. Their varied line of grinding, polishing and tapping machines are shown by many illustrations and full data are given relative to each style of machine. It is also stated that safety collars are provided when called for. Roughly speaking some 25 pages are used to display this line.

NEW CATALOGUE

The Graton & Knight Mfg. Co., Worcester, Mass., have issued a very interesting book dealing with their lines of standardized leather belting for power transmission. This bulletin is numbered 101, and is done up in very attractive style. The book consists of almost 100 pages and is well illustrated throughout.

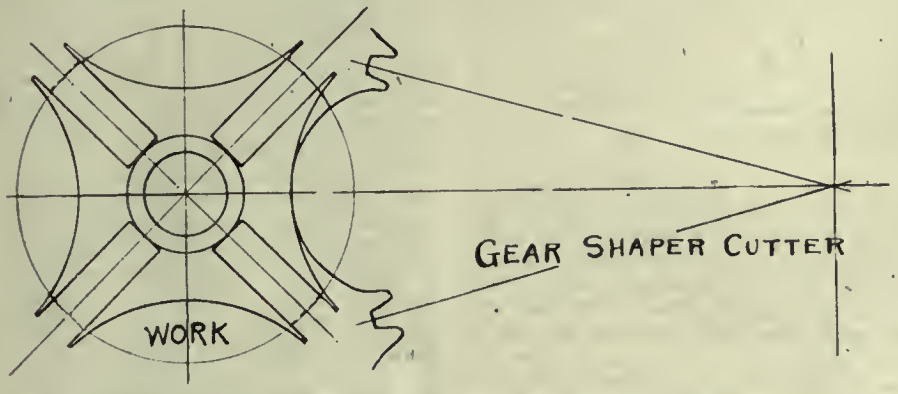
After the various lines have been discussed and their qualifications stated, the remainder of the book is filled with real live information for anyone using belting. Data of considerable value is given, in fact the latter portion of the book is a small text book in itself.

W. M. David, of the firm of Baines & David, Toronto, together with Mrs. David, is on an extended trip to Wales.

WHAT OUR READERS THINK AND DO

ANSWER TO PROBLEM

On page 398 in our October 28th issue, we published an article dealing with a problem in machining a Geneva movement for using in a moving picture machine. This problem seems to have aroused considerable interest, for we have so far had several replies to the query.



HERE IS ONE SOLUTION TO THE GENEVA MOVEMENT PROBLEM

The first of these is published below.

The Fellows Gear Shaper Co., Springfield, Vermont, on reading of the problem, decided it was up to them to state their opinion on the matter, and as is well known, they are well able to speak on manufacturing problems. To our mind, they state, this problem should be solved as follows:

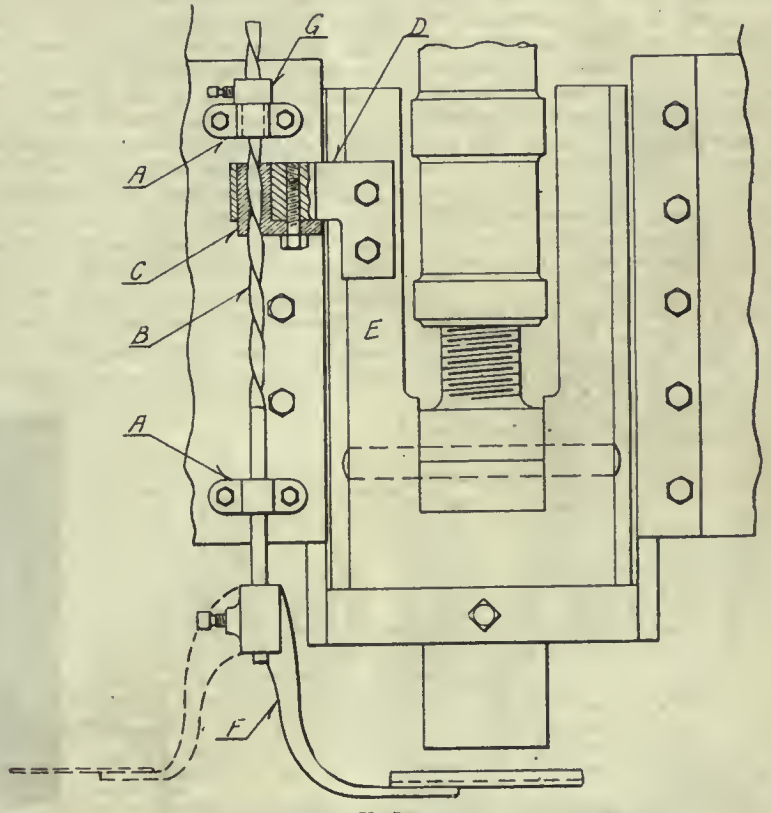
We presume that the difficulty encountered by the manufacturer in producing this Geneva stop mechanism is due to the curves indicated by the 29-64 radius and the location of the slots. It is almost impossible to mill four curves and have them all accurate, even though the cutter itself is accurate. This is due to the great difficulty of accurate indexing.

In our experience we have had a lot of irregular shapes to produce on the gear shaper, and a suggested method for handling this would be as follows: A cutter could be made which would accurately reproduce all four curves and at the same time cut part way into the slots, thus locating them. Then it would be a simple matter to finish the slots to depth with a milling cutter. The sketch accompanying this suggestion is self-explanatory as it clearly shows the outline of the proposed cutter.

PUNCH PRESS ARRANGEMENT

J. W. Rodgers

A handy arrangement for catching the finished product of a punch press is shown in the accompanying sketch. This particular device was operating on a washer press where the washer was blanked out in a duplex die and the finished washer carried up in the punch, from which it was ejected as the ram reached its top position. The two brackets A, A were secured to the stationary portion of the press in such a position as to allow free movement for the operating shaft B. This shaft is of square section and twisted or milled on the upper half of the length for operating in the nut C, the latter having a lug at one side for fastening to the bracket D, which is secured to the ram E. To the lower end of the rod B the bracket F is secured, and this bracket carries the pan that is swung under the punch as it comes to its top position. The swinging piece may be adjusted to the desired height by means of the collar G, the lower portion of this collar being turned to fit the bore of the bracket A.

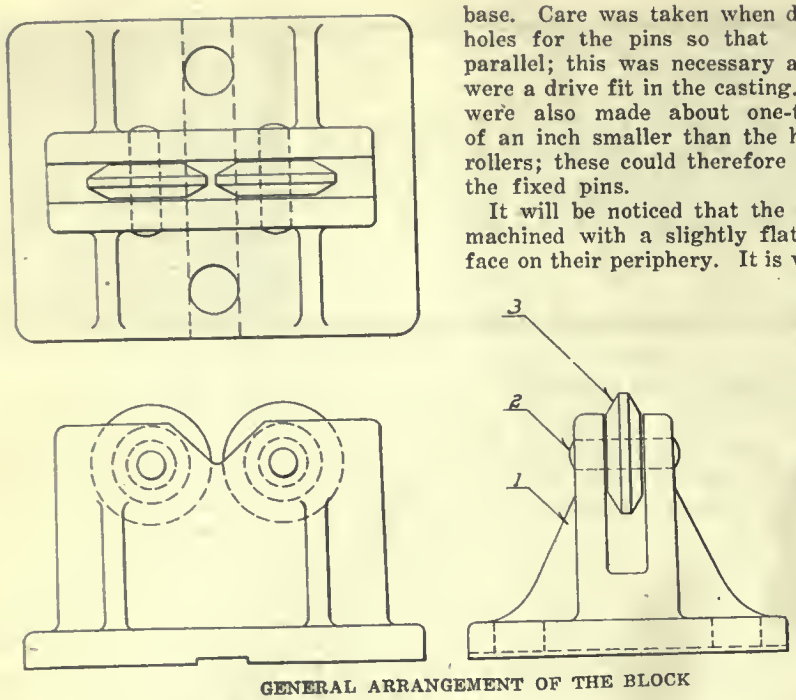


THIS SHOWS THE PUNCH PRESS ARRANGEMENT

TOOL ROOM ALIGNING V-BLOCK

By Robert Mawson.

A fixture that is practically necessary to any department where accurate tools are made is some type of aligning device. Before elements such as shafts,



GENERAL ARRANGEMENT OF THE BLOCK

studs or pins can be machined with shoulders or keyways, it is absolutely necessary to know that these parts are parallel. This is more so when such pieces fit the entire length or operate in bearings or bushings. If the least bend or misalignment were in evidence, it is obvious that the piece could not turn on its axis.

Of course a shaft could be tested in a lathe, but this would entail centring, which is an expense; and further, the process of testing would mean the use of a machine tool. The lathe is prevented from performing some other machining operation, therefore such procedure entails a double expense, unnecessary centring, and use of the lathe. To obviate this the tool shown in the illustration was designed and has been used successfully not only in our tool room, but also in the machine shop. The base (1) is made of cast iron, and is 5-in. long, 4-in. wide, and was designed with such generous proportions so that the tool would rest squarely under any desired condition.

The vertical walls of the base are provided with ribs so that the castings will not distort when in service. Two hardened tool steel rollers (3) 1½-in. in diameter are held by means of steel pins (2) in the vertical walls of the tool base. Care was taken when drilling the holes for the pins so that they were parallel; this was necessary as the pins were a drive fit in the casting. The pins were also made about one-thousandth of an inch smaller than the hole in the rollers; these could therefore revolve on the fixed pins.

It will be noticed that the rollers are machined with a slightly flattened surface on their periphery. It is well known that a perfect knife edge is the ideal condition for an aligning block roller, but when such a tool is employed for heavy or frequent use, it would prove impracticable, as the hardened sharp edge would soon be damaged. The roller as designed, therefore, provides us with a tool of lasting service and proves accurate enough for any purpose demanded in the tool room or machine shop.

By referring to the illustration it will be seen that two slots have been machined in the base, one at right angles to the other. These slots are employed to accommodate tongues of the proper width to suit slots in a milling machine table or any other machine tool. When the device is used in this manner, two of them are placed at the proper distance apart, to suit the element being tested. The V-blocks may then be fastened to the table, holes being provided in the base to accommodate such mediums. It is then a simple operation to test the part resting on the rollers, using an ordinary dial or other type of indicator. Revolving the piece around will show by means of the indicator if it is out of alignment and how much the error is. The element, when necessary, is then straightened in the usual manner and further tests made until the desired results are obtained.

REPAIRING OF BOX CHUCK WRENCHES

By Harry Moore

No attempt is made in this article to give instructions on the manufacture of chuck wrenches, but merely some instructive notes to the mechanic who may have one to repair occasionally.

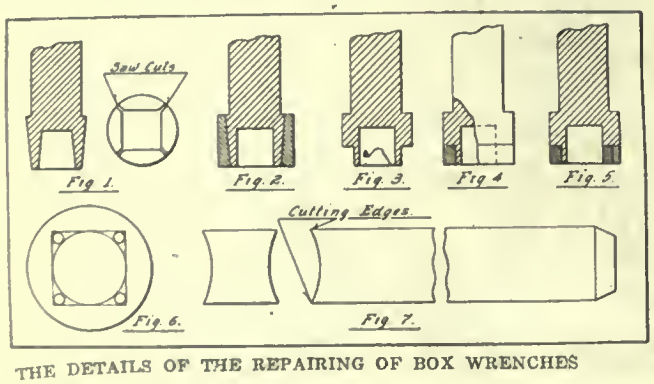
After a chuck wrench has been used for some time it will, as a general rule, have worked itself bell mouthed, and the moment you try to tighten with it will slip off the chuck square. A good way to make a permanent repair in such a case is to turn off the upturned edge to a slight taper as shown in Fig. 1.

The corners of the square are next slotted down with a hand saw to their full depth. A piece of machine steel is now bored out to fit the taper on wrench, and hammered on until the square is its original size once more. The ring is then faced off and turned, completing the job as shown in Fig. 2.

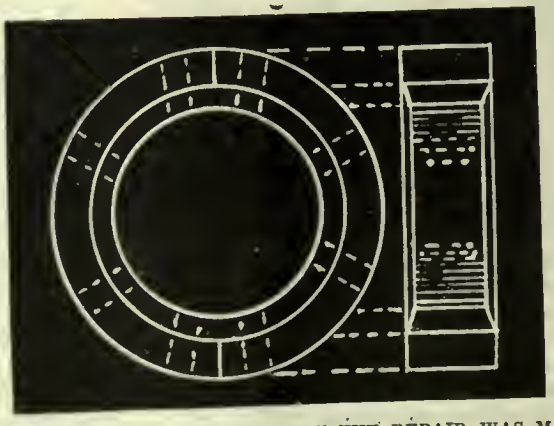
Hardened chuck wrenches do not give the same trouble with regard to wear, but as they are generally made of thinner stock, a piece will sometimes break entirely away. These wrenches are invariably a fairly close fit in the circular hole in chuck, therefore, a slightly different procedure is necessary in making a repair. The wrench is first of all annealed, and if the broken piece can be found it is sweated into place. The wrench is then turned as shown in Fig. 3. A machine steel ring is made several thousandths smaller, then shrunk on, the completed repair being shown in Fig. 4.

If the broken piece is not at hand the wrench is filed, or ground, and a piece made to fit as at Fig. 5, when the procedure is as before. The making of a chuck wrench is a comparatively simple matter if tackled in the proper manner. Very many mechanics fail to make a good job for two reasons: First, they leave too much stock for the punch to remove; second, they endeavor to force the punch in order to remove a lot of stock at once. The result in the first case is that the punches are broken, and in the second case, jagged, uneven holes are procured.

A good method for laying out a wrench



THE DETAILS OF THE REPAIRING OF BOX WRENCHES



BROKEN CAST IRON ROLL—HOW THE REPAIR WAS MADE

preparatory to drilling, is shown in Fig. 6. The four small holes are drilled first, then the large centre hole (which should be slightly smaller than the width of square) is drilled to the same depth. This method leaves very little stock for the punch to remove. This punch is made as shown in Fig. 7.

It will be noticed there are only two cutting edges on the punch. By making it this way a proper rake can be ground on the end which is impossible in the case of a punch with four cutting edges. It is placed on the lines at one side, driven home, then placed at right angles to complete the hole. It will be found that such a punch requires only a few light taps and leaves a clean, square hole.

MECHANICAL REPAIR ON A BROKEN CAST IRON ROLL

By W. S. Standiford.

In every mechanic's life emergencies will arise that call for rapid thinking and original work on his part in order to keep the wheels of industry running smoothly, as machinery breakdowns will happen in all factories and mills at the most unexpected times. In this article the writer shows how he made an emergency repair some years ago, on a broken roll, that lasted until the roll was worn out. When a bar of iron was going into No. 2 pass, a sliver on it jerked the tongs from the hands of roller, the tongs being jammed between the side of bar and the collar separating numbers 2 and 3 grooves; the result being that an eight-inch long section of collar was broken out. Owing to the conditions of the country, welding supplies were unobtainable, a new cast iron roll could not be gotten in less than three weeks, it taking four more days to make a new roll out of it.

As the company was anxious to get their rolled bars out on time, the writer was delegated to see if a mechanical repair could be made, provided it were possible to make it withstand the enormous side pressure exerted by the iron during rolling. A patch the size of the broken section and screwed to the roll was first thought of and decided to be impracticable, as both joints being near one another, would cause the patch to spring and shear off some of the metal on the bar.

I finally decided to turn the cast iron collar off of the roll altogether and replace it with a wrought iron one, the joints of the two halves being a long distance apart would enable the collar to withstand the spring when a bar was entered in the pass. In order to make the collar as rigid as possible under the circumstances, a slot having a slight taper and 2½ inches deep was cut into the roll, the width being 2¼ inches. After the slot was turned, a wooden templet was made, the length of the two halves were ascertained by the "cut-and-try" method, until when placed in the roll groove opposite one another, the wooden collar made a very snug fit, at the joints and bottom of groove. From these templets a wrought iron collar was forged by a blacksmith, put in lathe and turned with a taper matching the slot; the tapered section being a few thousandths of an inch larger so as to make a force-fit in the slot. One half of the wrought iron collar was forced into the slot as far as it would go, by the careful use of hammers, a heavy iron ring was then put over the half collar and four jacks, one opposite each joint, and the others being spaced equal distances apart. Part of the ring on the opposite side of the jacks was then filled with iron blocks. The jacks were then screwed up, care being taken to get equal pressure so as not to spring the half-collar, the pressure exerted by the jacks being continued until the collar section touched the bottom of slot. Collar was drilled and tapped to take three-fourths inch thick machine screws that extended one inch into the roll body. The other half of the collar was next fitted, a good job resulting. The roll was then put into the lathe and the collar turned to the same shape and size as the others. When the time arrived to use these rolls in the mill, the writer's heart was, for a few minutes' time, in his throat (metaphorically speaking), but the new collar withstood the heavy pressure admirably, a slight mark on the iron bars produced by the joints being removed in the finishing pass of the rolls. The net result of this repair job was: The company got their contract out on time. Over $300 was saved on a new roll, and the writer received an unsolicited raise in wages. No sketch is shown of the roll as readers are no doubt familiar with a set of rolls, and how they look. Should you not be conversant with the same, look up the issue of Canadian Machinery, July 15th, page 70. The sketch of the collar is self-explanatory.

See Page 440

TWO USEFUL FACING TOOLS

By "Draftsman"

The facing tools described are types that have many applications in the machine shop. They are intended for use on vertical drilling machines, but may be similarly used on horizontal boring machines. Fig. 1 shows a tool for facing the rim around a previously machined hole: The steel body A fits into the socket of the drill spindle and is secured by a set-screw bearing on a flat B. The centre of the outer end has a hole of two diameters, the inner one being threaded. Into this fits a tool steel pilot which is centred by the bevelled shoulder C. A slot through the pilot and across the end of the body carries the cutter D, whose projecting faces are backed off right and left. The outside of the body is threaded for a hexagon nut which holds the cutter by pressure on an intervening washer E. Two longi-

Cntinued on Page 443

DEVELOPMENTS IN SHOP EQUIPMENT

BRASS FURNACE OF NOVEL DESIGN

Metallurgical and chemical engineers for a considerable period of time have been endeavoring to solve the question of melting brass and other non-ferrous metals in the electric furnace in the most efficient and economic manner, realizing as they have that there was no question of higher production when melting electrically so long as certain metallurgical features of the process could be properly overcome. As a result of considerable research work, single-phase and even two-phase electric brass furnaces have been designed and put on the market, some of which seemed to solve the question of melting these metals electrically. It has, nevertheless, been a desire of those interested that a three-phase unit might be developed which would do the melting more efficiently and economically, and it will be interesting to engineers in the metallurgical and electrical field to know that such a furnace has been marketed.

The Volta Manufacturing Company, Limited, Welland, Ont., have had their engineering staff at work for some months past developing a three-phase electric brass furnace along the lines of what they considered would be the most efficient piece of apparatus to meet the requirements of the brass and non-ferrous metal industries, and have now put on the market a three-phase electric furnace which they claim is superior to anything heretofore developed for this class of work.

As will be seen by the illustrations of the furnace, the shell is of cylindrical design and is operated in an upright position—similar to the electric steel furnaces. The furnace is lined with refractory brick and the roof is also made of refractory material. It is provided with a cast iron base equipped with a motor-driven set of gears and rollers, which gives to the furnace a natural gyratory movement.

One of the strong features is that it is a three-phase unit, which means a balanced load on the lines of the power company and consequently a better power rate for the operator. It is quite generally known that many power companies, having a limited amount of power on their lines, do not desire and will not permit the operation of a single-phase unit on their lines except at a very high rate. On account of having three electrodes it is not necessary to maintain the same degree of perfect alignment of electrodes as is necessary with the single phase unit in order to maintain a high degree of efficiency and inasmuch as the arcing takes place between the three electrodes the arcing is distributed over a much wider area than in the single phase two-electrode furnace, consequently better melting facilities are provided.

As shown in the photographs, the electrodes enter the furnace through the side of the shell at points 120 deg. apart. Graphite electrodes are used and are supported on heavy cast iron arms which are provided with guides to take the electrode holder. The construction of these arms provides a substantially insulated sleeve around electrode, which is kept cool by means of a water-cooled collar. The latter is in the form of a ball point, and by this arrangement the position of the electrodes can be changed relative to each other, at the same time making provision so that they can be lowered or raised in respect to the metal bath.

The electrode holders move in the guides provided in the cast iron arms. This movement is obtained by means of heavy screws actuated either by hand or through a simple system of motor-driven gearing. The charge, as will be noted, enters the furnace below the electrodes, and it is not necessary to withdraw the same from the furnace at any time, either during the charging or pouring period. This eliminates any chance of electrode breakage due to the heavy scrap falling on them. It gives a longer life to electrodes and also eliminates the loss of time and the expense ordinarily incurred in removing and replacing the broken ones.

The roof of furnace is independent of the shell. This permits of the relative height of the roof to the bath being designed in such a manner as to insure the best melting conditions as well as the least possible fusing of the refractories. A vent hole with a light cover is provided in the roof of furnace which allows operating under tight conditions with perfect safety. Should gases, formed from the use of oily or dirty material in the charge, reach a certain pressure, they are allowed to escape through this vent in the roof.

In actual practice it has been found that the heat from the arc is sprayed down and over the metal in such a manner as to heat the whole surface of the metal evenly. The effect of this is very important as it reduces the volatiliza-

NOTE THE BASE AND ROLLERS WHICH GIVE THE FURNACE THE GYRATORY MOVEMENT

GENERAL VIEW OF THE FURNACE. NOTE THE MOTOR AT SIDE

tion losses in the metal being melted to a minimum, and the linings, not being subjected to any high temperatures, last much longer. The motion given to the furnace by means of the combination of gears and rollers, has proved itself to be a very efficient and natural mixing, one by means of which superheating of the metal is practically eliminated.

This furnace has been subjected to some very severe tests and is said to have proved itself an efficient and economical melter, very simple of construction and easily handled. When running on yellow brass, metal has been produced with a current consumption as low as 225 k.w.h. per ton of metal produced, and when running on aluminum-bronze the current consumption averaged about 300 k.w.h. These figures were not taken at a time when the furnace was operating continuously and it is only reasonable to expect that the power consumption will be considerably reduced when the furnace is thoroughly heated and is being operated continuously. At the present time the manufacturers are producing these furnaces in the following standard sizes: 500 lbs., 1,000 lbs., and 2,000 lbs., having a transformer capacity of 125 kw., 175 kw. and 300 kw. respectively.

EVER-HOT SOLDERING IRON

The Peterson-Plummer Manufacturing Company are now making an ever-hot soldering iron which is light in weight and a convenient size for every requirement. The gasoline is contained in a reservoir in the handle which is made of seamless brass tubing, the pump being located at the outer end. The flow of gasoline is through cotton wick contained in a rustproof iron pipe between the handle and the burner. The burner is so designed that it may be used effectively in any kind of weather or high winds. The iron is fitted with one large and one small point.

TWO USEFUL FANCY TOOLS

Continued from Page 441

tudinal grooves F in the pilot gather any grit that may pass.

When in use the cutter removes metal until the pilot bears on the top of the pin G, on which the work is mounted. The tool may be reground many times and its cutting edges will always be the same distance from the end of the pilot, thereby uniformly limiting the cut.

In Fig. 2 is shown a lighter type of tool for facing black hexagon nuts in the simple adjustable jig. Here the body fits into a tapered socket and the nut is knurled. The pilot hole is of one inch diameter, and the threaded part of the body has two through slots for the separate cutters. The latter are held, at the lower end, by a collar with two grub-screws at right angles, and this also pinches the pilot. At the upper end each cutter is retained by a bevel engaging that of the thick washer.

Such a tool has quite a long life before the cutters need to be renewed.

NEW THINGS IN MACHINE TOOLS

MULTI-SPEED GRINDING MACHINE

A grinding machine that is very suitable for both production or tool-room work has been placed on the market by the Wisconsin Electric Company, of Racine, Wis. The device is provided with a set of interchangeable spindles and pulleys, so that a wide range of speeds is obtainable. Dust-proof ball bearings are fitted to the spindle. The device can be swiveled to any desired angle for every class of work.

TOOL GRINDING MACHINE

A motor-driven ball-bearing tool-grinding machine, fitted with a quick make and break oil switch, is now being manufactured by the Ransom Manufacturing Company, of Oshkosh, Wis. A starting pedal is placed at either side of the base of the machine, and when the foot pressure is released the machine is automatically stopped. Self-aligning S K F ball bearings are fitted to the spindle. The machine is operated by means of a 3-4 h.p. General Electric motor.

QUICK-ACTING MACHINE VISE

The Nelson Tool & Machine Company of Bloomfield, N.J., has recently brought out a new machine vise, and it is claimed that no hammer is needed in bedding the work on the vise bottom or to the parallels. The operating screw is set at an angle so that when pressure is applied the sliding jaw shows no tendency to lift upwards. The vise is made in two sizes. six inches wide by two deep and opening of 5 3-4 inches, and four inches wide by 1 1-2 inches deep, with opening of four inches.

IMPROVED ABRASIVE DISK

An improved type of abrasive disk for use in disk grinding has been placed on the market by the Gardner Machine Company, of Beloit, Wis. The construction of these disks increases the efficiency in grinding operations. The thickness is double that of the ordinary glue-bond disk, the bond being a special cement that powders away during the grinding operations. The corrugated surface causes the abrasive grains to assume a better position, always presenting new cutting points to the work.

DRILL RACK

The Peerless Machine Co., Wis., have placed on the market what is known as a gauging drill rack. This rack provides a place for drills, and each drill that is in the rack has been accurately gauged and must be in the correct place. This rack provides a practical gauge for all sizes of drills and reamers ordinarily used in any shop, large or small. In highly organized shops these racks are often installed in the tool crib where one rack may be used exclusively as a gauge while another series of racks are used to take care of the different tools.

In small shops these racks are sometimes attached to the drill press, and a complete set of drills maintained at the machine tool. This rack is claimed to meet a need which has long been apparent in all shops, namely, on account of tools slipping in the chucks, the numbers indicating the drill sizes are soon destroyed or badly blurred, and a practical gauge is desired to eliminate errors and save the time lost in securing a micrometer or gauge.

Quoting New York Funds

SOME weeks ago this paper, in an interview with J. Vernon McKenzie, formerly trade commissioner at Glasgow, referred to the fact that some Canadian exporters were asking for payment in New York funds. He explained that there was marked resentment to this practice on the part of many of the Old Country firms, the latter holding that Montreal quotations should be sufficient to cover the situation.

An Ottawa despatch this week refers to the same practice, complaint being made that trade commissioners are finding decided objection to this system, which they regard as trying to pinch off a little extra from the buyer.

One section of the Ottawa despatch points out that Canadian Trade Commissioners in every part of the British Empire state that general indignation is expressed by importers that Canadian firms almost invariably collect for goods exported in United States funds. Latterly the complaint has been that Canadian steamship companies also collect for freight on such goods in United States funds. One Trade Commissioner reports a British merchant as saying, "You keep asking us to give a preference to Canadian producers when buying because it is a British country. Why should I do that when Canadian exporters always ask us to pay in United States funds? Are we to believe that Canada is only a commercial adjunct to the United States? It looks so to us when such things happen."

Much of the material that some Canadian manufacturers use is bought in the U. S. market, and paid for in New York funds, but no doubt provision is made for this in fixing the selling price. Unless there is some very good explanation to be offered on behalf of the Canadian manufacturers adopting this practice, it will be charged that they are taking undue advantage of a passing situation, and in so doing injuring their reputation to a very serious degree, all of which will be hard to overcome in the future when goods are plentiful and orders badly needed.

Investing in New Machines

A STORY comes from Hamilton telling of the demonstration given to the civic authorities of a new mechanical excavator. The machine cost $10,000 or so, and, naturally, the civic officials wondered if they were going to get that much real value for their money.

After the machine was seen in operation it was estimated that forty men would be required to keep up with it, and one of the controllers remarked, "People criticized the spending of this much money on a piece of machinery, but this proves to me that it was a wise investment."

That same situation comes up a good many times in a good many places. Firms look at the amount of money that they will have to pay for a new machine, and they keep on looking at that sum until it grows into a foothill or a mountain.

They do not look on past that obstacle to see what is on the other side in the way of greater production and better work. They have an old machine, and by some strange process of mental juggling they think every extra day's work they take out of the carcass of that old thing they are just that much ahead.

The amount that can or should be spent on a machine can be safely judged by what that machine will do. If it can produce sufficiently in excess of an existing tool to pay its way and then some, why not let it?

There are cases where an old machine is humping along, causing the man who runs it considerable trouble and loss of time, putting the shop "up against it" if that man happens to be off for the day—and yet they imagine they are getting easy money by not having to go into the machine tool market and replace the old tool.

And once they get into the market and buy the new machine, put it in line and see it perform, watch the production records and compare them with the best limpings of the old tool—well, as the civic officials in Hamilton with their excavator, they are convinced that it was a good investment and a money maker right from the start.

You can save money in more certain ways than by hanging on to your old equipment.

Sessions of the tariff commission convince some critics there is no connecting link between farmers and manufacturers. Is that so? How about pig iron?

The Optimist.

Poor Insulation or a High Tension Spark

There are certain mechanical laws that must be conformed with in any line of activity. When some or any of these are violated, there is going to be trouble. A recent case occurred at Buffalo, where a number of men were cruelly burned, most of them fatally, when new apparatus in a generating station went wrong. We asked T. H. Fenner, the editor of Power House, to discuss this matter, and in the following he has done so.

THE generation of high potential electric current and the transmission of it over many miles of country is attended by comparatively few accidents in proportion to the amount of electrical power development. The chief cause of fatalities through high voltage electric lines is by the coming into contact with them of linemen engaged in their usual work of running new lines, and repairing and locating faults in existing ones.

Accidents in the generating stations themselves are happily few in number, and fatalities even less, and with the constantly better efforts towards safety that are being put forth, the number should steadily decrease. It is therefore with something of a sensation of horror that we read of the destruction of no less than eleven men, almost instantly, through an accident, which, although it may have happened before, does not recur to our memory.

The accident in question was the explosion by some fault in the insulation, presumably, of the oil used for the cooling of a transformer in the Tonawanda power house, Buffalo. The change of electric current, which is generated at high pressure, to current at a much lower pressure is accomplished by means of transformers which consist of two separate coils of wire wound on iron cores. The high potential coil will consist of a large number of turns of small wire and the low potential side of a less number of turns of a larger wire. The effect of the high potential current being passed through the high potential coil is to induce a current in the low potential coil of the same periodicity, and the relation between them is such that if the high side A consists of 50 turns, and the voltage is, say 100 volts, then if the low side consists of 25 turns the voltage in that coil would be reduced to 50. This, of course, applies to any voltage, and any relation of the number of turns. There is little loss between the two sides, by which we mean that the product of volts and amperes in the low side will be almost the same as that of the volts and amperes in the high side.

What loss there is appears in the form of heat, and in order to carry off this heat, it is usual to immerse the whole apparatus in a bath of oil. This oil in turn has very often coils running through it which carry a circulating stream of cooling water, and thus the heat is effectually dissipated.

It was the bath of the oil that exploded and thrust forth a sheet of flame which licked out the lives of eleven men in an instant. The cause of the accident is stated to have been a short circuit. The apparatus was under test at the time, and it is probable that the oil bath had been raised to a dangerously high temperature without it being noticed.

A piece of defective insulation and a high tension spark would easily supply the little extra heat necessary to cause the flash. No doubt the enquiry that will follow will throw light on the exact cause of this sad accident, and make the recurrence of it extremely unlikely in the future.

A Buyers' Market Here

HERE is the opinion of a man whose business it is to watch the markets. T. F. Bentley, writing in a recent issue of "The Purchasing Agent," says:—

"There is a definite downward trend in all commodities and in all countries. Prices are not declining because of the election campaign, or because it is harder now to get funds for speculative purposes than it was a year ago, but because business is gradually getting on a healthy basis—that is, we are coming again into a "buyer's market," which will be better for general business. A buyer's market means that the buyer may require definite information as to the price he must pay, not only for immediate needs, but for a reasonable time to come. It means that the buyer may demand reasonable assurance that the goods he agrees to take and pay for will actually be delivered and will not be diverted to some other point that may offer a trifle more payment. Finally, it means that the buyer may insist, within reasonable limits, that specifications of quality be carried out."

What's the use of having your trousers creased, boots shined, clean shave, clean collar and latest tie, fine line of talk about the weather, politics, reduced prices, Bolshevik, League of Nations, if you can't succeed in getting the customer's signature on the dotted line?

What the Business Papers Say

"Marine Engineering."—This is a plea for greater frankness on the part of engineers and manufacturers, as a matter of policy for their own advantage. There is a very proper idea that a man may well keep his private business to himself and that corporations may well practice a like reserve. But when a man wants to sell something it at once becomes a matter of business to the purchaser. There are, of course, instances in which the purchaser may well use his purchase without too much curiosity; the average man had best wind his watch regularly and think no more about it till he wants to know the time. But usually a machine needs intelligent care, and the more the user knows about it the better service he will get from it.

The Changing Foundry Aspect

"The Foundry."—During the past two weeks the shift and readjustment in foundry conditions has been most rapid. For a short time previously a decrease in demand in most lines had been noted, and in some directions this even had taken the form of cancellations of existing contracts for castings. To-day the cycle has swung entirely around until with few exceptions a buyers' market for castings governs, and some shops are taking on work foreign to that which they have followed for the past two years in order to keep their forces engaged.

What Determines Selling Price?

"Iron Age."—"In the textile trade and in others in which the ultimate consumer buys over the counter of a store, it is true that the declines came first in the raw materials and that wholesale markets underwent drastic readjustment. But the reductions that have been made in retail prices, most of them moderate thus far, were not the result of a decrease in the actual cost of the goods sold at retail. The dealer's stocks had been bought at high prices and were sold at reductions, going in some cases below cost, because they could be replaced on the dealer's shelves at prices considerably below what he had paid for them. Cost did not determine selling price."

Boilers Keep on Exploding

"Power," (New York).—Certain states that have adopted the A. S. M. E. Boiler Code have exempted oil-country and agriculture boilers with the exception of periodic inspections. Undoubtedly in some cases this has been an expediency resulting from political influence and is most unfortunate, especially when it is considered that many of these boilers are of lap-seam construction and are operated by very unskilled labor. Many of these boilers do explode and the loss of life is appreciable.

MARKET DEVELOPMENTS

Price Talk the Market Topic for This Week

Some Reductions Have Gone Through, But the Most of the Firms Have Made No Move Yet—The Scrap Market in Canada Has Been Pruned, But Business is Dull at the Lower Levels.

PRICES and price talk engage the attention of the market this week even more than before. There is a sincere desire on the part of a large section of the trade to get down to a workable basis as soon as possible, but there are very real difficulties in the way, chiefest among these being that costs do not show much tendency toward lower levels.

One maker of machine tools in Canada stated this week that there was very little chance of them announcing a lower price under present conditions, as there was nothing in their cost of manufacturing that was showing a lessening. However this may be, the fact remains that a number of American makers of machine tools have announced reductions to their representatives in Canada, and they are now working on the new schedule. New York is to be the centre of interest this week, and it is generally believed that following the convention of the National Machine Tool Association there will be some announcement, concerted or otherwise, dealing with the price feature. Cuts already made range from 15 to 20 per cent.

Small tools have been reduced in Canada by some ten per cent.

The steel market itself is quieter, but there is still a good deal of business to be secured. Manufacturers are not buying in large quantities, nor have they for some years past. The reasons for this are two in number: (1) they could not get the material if they were able to pay the price, and (2) the price has been too high in most cases to get them away from the hand-to-mouth class. A slight reduction is announced this week in warehouse prices of bar iron, now selling at 5.50 per pound. Most of the bar iron trade is supplied from the Canadian mills.

The scrap metal market went through a severe pruning at the hands of the dealers this week. They cut fast and deep into the lists they had been working on for buying purposes. Whether this decides the matter remains to be seen. A dealer can name his price, but if the seller will not accept it there is still room for an argument. Just now there are only three or four lines that are wanted, and these are scarce, and mostly in the iron and steel lines. Copper and brass scrap are drugs on the market, and business is stagnant.

BUYERS IN MONTREAL MARKET WAITING FOR SETTLED PRICES

Special to CANADIAN MACHINERY.

MONTREAL, Que., Nov. 11.—It is seldom now that we hear of mills complaining of a shortage of raw materials for the steady maintenance of plant operations. There are cases still reported where delivery to the mills has been interfered with, but this situation is overshadowed by the more serious one of the declining number of orders being placed on the books, and to the fact that the supply is now equal to, if not greater than the demand. This condition evidently is quite general throughout the steel industry, and is likewise more or less true with all lines of actlvity at the present time. The interest in the market appears to be influenced by the price adjusting that has featured sales activities on many commodities. The downward trend that marks the movement of materials of nearly every description has acted as a limit gauge by which the majority of buyers are now measuring their requirements. Current purchases are based on urgent needs for immediate consumption, and with declines a factor of weekly or daily occurrence, the place in the sun will be occupied by the seller rather than the buyer. However, this policy of conservatism may be carried to the point where industrial depression would loom up as a serious factor, as present producing costs will hardly permit of continual cutting of material prices, unless something is done to enable the manufacturers to make these reductions without serious loss to themselves. Curtailment in mill and blast furnace operations has been among the recent developments in American steel centers, and in consequence many men have been temporarily unemployed. This action on the part of producers has been found necessary, as it would be inadvisable to continue manufacturing materials at existing high costs when the demand for the product is showing a marked falling off. The movement in this district is steady in character but the volume indicates that requirements are becoming less. Price quotations given last week still hold, but further declines are not improbable.

Prices Unsteady; Demand Light

Weakness and quiet demand continue to feature the metal situation and, with few exceptions, the demand is below normal. The movement of galvanized sheets has shown slight improvement and general distribution is much better. Ingot metals are moving steadily but volume is light, evidently indicating that purchases are made with the idea of meeting the needs of the present rather than the acquisition of material for early future requirements. The prices on all ingot metals are at present unchanged but a further shading is not improbable.

Retrenching Attitude Evident

Dealers here are interested in the possible action to be taken at the meeting now being held in the States by the

DIAMOND
DISC GRINDERS

Good grinding in fast time has made the Diamond popular in a host of shops. The right design and build eliminate vibration and give the operator a perfect surface every time. There is a suitable size and equipment for every surface grinding job you have. Workmanship and material of "Diamond" quality throughout.

May we send you catalogue?

machine tool builders. It is expected that a decision for price revision will be arrived at during the meeting, and the trade will be advised of such action in the very near future. There are many indications of the trade requiring equipment, but the attitude of the buyer today is one of retrenchment in face of lowering prices, and every effort is made to extend the time when the placing of orders for new equipment will become imperative. It is nevertheless true that these placements will ultimately be made, but where a few short weeks may mean a substantial saving in tool cost, the user is evidently content to weather the present storm of uncertainty and inconvenience in order to effect the saving that would result by the reduced cost of the new tools. On the other hand, the slackening of trade, that already shows on the horizon, may spread to many quarters and minimize the necessity of the manufacturer to purchase the equipment which, apparently, a few short weeks ago, was so urgently needed.

Low Prices No Inducement

The old material situation still dwells in a listless atmosphere, as the buying at the present time is exceptionally quiet. What trading is carried on is largely that of local movement in supplying foundries with regular requirements. Even here it is reported that demands are less insistent than formerly. The industrial situation generally offers little inducement for the absorption of scrap for future consumption, and with the uncertainty that continues to feature trade outlook, the prospect for even normal buying during the remainder of this year is not encouraging. Some dealers go so far as to say that trading will continue dull until the spring. The decline in price quotations noted last week is still effective and further shading is probable, in face of the quiet demand.

SOME REDUCTIONS HAVE BEEN MADE

Several Lines are Working Now Toward a Lowered Selling Schedule

TORONTO.—In most lines of the machine tool, iron and steel trade this week business would plead guilty to being very quiet. There are variations from this both ways, some firms claiming that their business is good, going ahead of the same month last year all the way along, while others, on the opposite side, report trading as very quiet and with no large buyers in the market.

It cannot be denied that there are a lot of machine tool quotations out just now, and if they could be converted into real business there would be nothing the matter. The turning of these quotations into real business is not being done rapidly. There can be no doubt that many buyers are anticipating something in the way of an announcement regarding prices or better conditions. Whether this would result in more business being placed at once it is hard to say. Canadian Machinery asked one of the dealers today if such would be the case, and he replied: "That is something I would not undertake to answer. There are some cases where it would not make any difference were I able to go out with a reduction of 30 per cent. On other lines it would make a difference. The standard lines are the ones that are looked to to set the pace in this matter of price reduction. Some of the newer companies sent out notices some weeks ago that they would allow us to deduct as much as 20 per cent. from their April lists, but this did not make any marked difference in sales. There are other cases, though, where it will make a difference. One of the largest makers of boring mills has announced a reduction, and it amounts to quite an item, especially when the quotation in the first place runs around ten to twelve thousand dollars. The reduction is around 15 per cent., and the company, in its report that it is prepared to do this, warns the buying public that they have gone the limit in doing this, and that prices will stand for a long time to come without going any lower."

Questions at other of the machine tool houses brought out the information that no reduction in prices had been authoriz-

ed, although there is a general feeling that something more definite in this can be expected following the meeting of the National Machine Tool Builders' Association at New York.

Discussing the matter of prices with an official of one of the machine tool companies in Canada a few days ago, Canadian Machinery brought up the matter of prices and inquired whether there was any intention on the part of the firm to move toward a lower schedule. The answer was: "Not as long as present costs keep up. The machines we have on hand were made of high cost material, and were we to cut the price without any cut in the price of the material in them we would lose money. I don't see how Canadian makers can cut prices unless there are reductions in materials and wages."

There is a growing feeling in the market that the matter of prices will be dealt with in a definite way shortly. The absence of any announcement does not help matters, and the dealers would be strengthened were something done one way or another.

The prices of high-speed steel tools have been reduced 10 per cent. and on some other lines there have been reductions made in carbons. The list on high-speed drills, for instance, is divided now as follows: ½ inch and under, net, 33-64 to 1 inch, plus 10 per cent.; over 1 inch, plus 20 per cent. The list formerly ran from list plus 10 to plus 30. The new prices came into effect on the 8th of the month, bearing out the intimation in these columns of last week that an adjustment was being made in prices of small tools.

"Will you sell any more at the new prices?"

"That remains to be seen," was the reply of one dealer. "I do not think the price has much to do with it, although the buyer will very often insist that it has. Just now business is small, but there are a fairly large number of the small pieces. We are looking for renewed buying before very long."

Steel Market is Easier

There are few Canadian orders on the books of the premium mills in United States, about the last of this material coming over during the week. Many of those who find it necessary to import are promised consideration very shortly by the Steel Corporation, which is beginning to catch up with some of its bookings. There are certain lines that will still come from the premium mills. For instance, sheets, although Canadian rolled are now available in better supply, will be brought in from the premium mills, but the price is better than prevailing for some time, the chances being that buying can be done now at slightly over 6 cents per pound, a real improvement on the figures that were prevalent some few months ago.

There has been a reduction of $5 per ton in the warehouse price of bar iron in Toronto. This will, of course, also take in bar steel as well. The price is now 5.50 cents per pound, still a mark that stands as very high compared to the usual run of prices for this commodity. Bar iron is coming quite freely from the Canadian mills now, and they are able to look after the great bulk of the business offering, with the exception of the large size rounds and squares.

One Toronto warehouse had a voluntary reduction from one of the premium mills during the last week.

"Were you surprised or insulted?"

"Neither," came the reply. "We are used to anything happening now." Lest there be any doubt, it might be added that the warehouse accepted the reduction.

Delivery of tubes is only fair, prices are firm, and there is a lot of business yet to be attended to.

"Firms are not buying anything that is not absolutely necessary yet," explained one of the dealers to Canadian Machinery to-day. "In no case is a firm taking on stock material. From the 15th of November each year until the end of the holiday season we never look for a great amount of business. It is between seasons, and a few off weeks need occasion no alarm."

POINTS IN WEEK'S MARKETING NOTES

American builders of machine tools are getting better labor results than for months past.

—

Some reductions in machine tool prices are out now, varying from 15 to 20 per cent.

—

National Machine Tool Builders' Association meets in New York on November 11 and 12.

—

U.S. railroads are expected to come into the market with fairly good lists early in the year.

—

Scrap metal prices, with the exception of a few "whites," have been severely pruned. Very little business is offering.

—

Our Pittsburgh correspondent claims that by the first of the year the independent steel mills will not be running over 60 per cent.

—

Pig iron prices have broken quite sharply, and a large tonnage would probably set a new low market figure.

—

High speed small tools are reduced 10 per cent. by Canadian makers. The new list became effective November 1st.

—

Bar iron is selling at 5.50c per pound in Toronto warehouses.

Scrap Prices are Cut

Scrap dealers are out with the axe this week, and they have cut deep into the price schedules that have been standing for some time. Heavy melting, wrought axles, scrap rails, machinery cast iron, car wheels, steel axles and stove plate are the items that escaped notice when the killing was on. Otherwise the list is pretty well battered down. Here is the way in which the largest yard sized up the situation:

"Conditions are, if possible, worse than last week, and there is no guarantee that prices are staple yet. The Steel Co., we hear, is interested in heavy melting steel but at a lowered price, perhaps down three or four dollars from last week. For the first time in a year cast iron shows signs of weakness, and prices are not strong. Steel turnings are also weaker, delivered consuming districts; there is no market for borings and turnings here, although some may be placed across the line. Agricultural and railroad malleable is not in demand at all. Scrap pipe is a drug on the market and cannot be sold. Car wheels and grate bars are in fair demand. Stove plate is weakening, and rerolling rails are a drug now.

"In the non-ferrous lines heavy copper and wire shows a further decline, and dealers are now offering for No. 1 copper 12 to 12½ cents; light copper is quoted at 10½ cents; No. 1 composition scrap, which is the firmest of all non-ferrous metals, is quoted at 12 cents, the same as No. 1 copper wire. There is no market for heavy yellow brass, and the quotation of 7½ cents is nominal.

"I believe," he said in conclusion, "that there are many dealers in the scrap metal business who are not making their salt at present. Business is poor and there is nothing in which to speculate with a fair chance of profit.

TO GUARANTEE THE COMPANY'S BONDS

Town of Paris to Lend Aid to the MacFarlane Engineering Firm

A proposition has been made to the Paris, Ont., Council by the MacFarlane Engineering Company for the municipality to guarantee bonds for the firm to the amount of $40,000. A committee appointed to investigate made a highly favorable report to a special meeting of the Council as regards the security offered. There were also present some thirty representative members of the Board of Trade, of whom a number spoke in favor of the adoption of the offer. On request of Mayor Patterson, a unanimous vote was passed to support the Council in the movement. A by-law has been prepared and will be submitted to the ratepayers early in December. The firm has already some 75 or 80 men employed, and it is confidently expected that within a few months after the passing of the by-law 200 men will be on the pay roll.

TOOL MAKERS IN U.S. ARE GETTING BETTER RESULTS FROM WORKMEN

Special to CANADIAN MACHINERY.

NEW YORK, Nov. 11.—One factor which has been somewhat disturbing to business—the presidential election—is now out of the way, and the result is such as to inspire a greater degree of confidence in the early recovery of trade from the depression in which it now finds itself.

However, there are other things to be adjusted before renewed buying on a fairly large scale may be expected. One of the most important is the deflation of prices, which has scarcely touched the machine-tool industry as yet, either as regards costs of manufacture or selling prices.

In a measure, the manufacturers of machine tools have brought about slightly lower labor costs, this being due not so much to reduction in basic wage rates as in greater individual efficiency among workmen. For example, there are many plants which have discharged 10 or 20 per cent. or more of their employees which find themselves getting as much production from the force remaining as they were obtaining with the entire working force. In other words, the men who have jobs are working harder to retain them. This productivity is of even greater importance, from the standpoint of the manufacturer, than any reduction in basic wage rates, which are probably none too high if the men will turn out the work.

There have been a few reductions in selling prices by machine-tool builders, notably one of 15 per cent. put into effect November 1st by a large New England maker of turret machinery. Other reductions are known to be under consideration, but action will be deferred until after the meeting of the National Machine Tool Builders' Association in New York on November 11th and 12th. It is regarded in the trade here as practically certain that many tool manufacturers will go home from this meeting prepared to make substantial cuts in prices, say from 10 to 20 per cent. It is contended, however, that this will be about the limit, as machine tool prices have not been abnormally high.

Immediate business prospects are slightly better in some respects. The Erie Railroad has put out inquiries for six or eight tools, and more inquiries are expected from the same road. One or two other Eastern roads are also on the point of submitting lists to the trade, and this, it is hoped, is the beginning of railroad buying in the East. There has been a fair amount of railroad buying at Chicago in the last few months, but the Eastern roads have done practically nothing since the lines were returned to private ownership. The new freight and passenger rates have been in effect for more than two months and railroad earnings are showing a fair increase; hence it is expected that some of these earnings will soon be expended for rolling stock and shop equipment. In pre-war years it was customary for the railroads to issue their lists of tool requirements about January 1st and do their heaviest buying in February. There is some reason to expect that the same will be true in 1921.

PITTSBURGH NOT QUITE SURE WHERE PRICE LEVELS MAY REST

Special to CANADIAN MACHINERY.

PITTSBURGH, November 11.—There is no material change in the iron and steel situation as to the volume of demand appearing in the open market, the demand being extremely light. The amount of stocks consumers had when the market turned soft cannot be estimated closely. It may have been considerably greater than buyers represented, when they were importuning mills and furnaces for heavier shipments, but whatever the stocks are the buyers wish to reduce them, and they desire to have as small stocks as possible on the inventory date. The quadrennial election last week has had no appreciable effect on the general situation.

The changes that have occurred in the past week have been in connection with prices and the volume of production, both showing more or less declining tendency. The decline in prices is spotty and irregular, affecting some products greatly, others scarcely at all. The decline in production, in the aggregate, is steady, though it is not steady as regards any individual producers.

Pig Iron Production

Since furnaces began blowing out, early in October, about two score stacks in various parts of the country have gone out, the greater part being late in October and early this month, while there were proportionately somewhat more steel works furnaces than merchant furnaces that went out. The blowing out occurring so largely late in October, the month's output was not greatly affected, and with the operating furnaces in receipt of better supplies of coke the month's output as a whole showed an increase over the September rate. In fact the October rate was the best shown for any month this year excepting last March, being about 39,000,000 tons a year, while the rate last March was about 40,000,000 tons. The rate now, however, is doubtless well under 37,000,000 tons.

In the matter of steel production the curtailment depends on the state of order books. As the Steel Corporation is very well filled with business its output has not decreased, and has possibly increased a little. Those of the independents that pursued a relatively conservative course in the matter of prices are moderately well filled, but with cancellations and suspensions are unable to run full, and thus a number have reduced output only by say 10 or 15 per cent. Others, with lean order books, which they cannot replenish to any great extent by cutting prices since there is little business obtainable at any price, have had to curtail more, and probably quite a number of small independents are running at 60 per cent. or less. The necessity for curtailment strikes one mill after another. At the present time many mills are counting up how many weeks their order books will carry them at 50, 60, or 70 per cent. By the end of the year the independents, on an average, will hardly be operating at more than say 60 per cent., and perhaps the average will be under 50 per cent., while even without any improvement in business the Steel Corporation ought to be able to maintain its present rate of output until April or later.

Steel Prices

On bars, shapes and plates the common quotation among independents is now 3 cents. In instances an independent is asking more, but merely as a nominal price to protect contracts on books. On bars there is little, if any shading below 3 cents. On shapes a concession of a dollar or two a ton would probably be obtained without difficulty. In the case of plates there is much irregularity, but it requires an attractive inquiry to bring out a cut price.

In sheets, particularly black sheets, the market seems to be tumbling rather than declining. The market on black sheets had been going down at the rate of say a quarter cent a week until a few days ago 6.25 cents became the common quotation for mills that were really seeking business. There are various reports of prices being done under this figure. It is believed that several mills would quote 6 cents very promptly if they saw chances of booking an order that would put them in a comfortable position for a week or two, say a tonnage running into four figures. It is reported, but not confirmed, that a valley mill sold 2,000 tons at 5.75 cents. Another report is that a mill made a first quarter contract at 5.50 cents, but this is doubted. In one well-informed place the prediction is made that first quarter business with independents will be done, when the time comes, at about a cent per pound above the Steel Corporation price, which has been 4.35 cents, and is likely to remain there, and that when second quarter business is done it will be at about the

Steel Corporation level. The corporation will open its order books next month for the first half, but in both sheets and tin plates it will have to carry over about three months of work, so that the new contracts will be in reality for second quarter. This will make no material difference, of course, since the contracts will be with regular customers, who will be getting deliveries in the first quarter on old contracts instead of new contracts.

Pig Iron Breaks

The condition continues in the pig iron market that each inquiry of any size brings out further price declines. The pig iron sellers, who consider themselves salesmen when iron is scarce and they can get higher prices simply for the asking, are now exhibiting the form of salesmanship that consists in quoting a prospective buyer a price and then explaining that the price is largely nominal and they want to hear from the buyer again when he is ready to close. Hitherto the foundry iron market has been considered $45 valley, after the declines from the $50 price reached in August, and forge would naturally be say $1 less. In the past week an inquirer for forge was quoted all the way from $44 to $41, while an inquirer for No. 2 foundry was quoted from $45 down to $41. No purchase was made in either case, the prospective buyers concluding to allow the sellers more time in which to make up their minds positively. On an inquiry for 2,000 tons of basic for the east $38.50 valley was done, or $1.50 below the market as previously established. Bessemer has been offered at $42, or $3 off, finding takers only to the extent of two carloads. An inquiry now pending for 150 tons will bring out a further cut. We quote the market at the moment as follows: Bessemer, $42; basic, $38.50; foundry, $41, f.o.b. valley furnaces, freight to Pittsburgh being $1.96.

Connellsville furnace coke for spot shipment is down $1.50 in the week to $8.50 per net ton at ovens. In the two weeks preceding there has been a decline of $7. Foundry coke is now quotable at $10.50 to $11, though in remote districts, where the buyers have not learned the full size of the slump, $12 has been paid in some instances in the past few days.

No one knows where coke and pig iron will land in the final adjustment, and various predictions are made, and can be defended to an extent, but in quarters where there is the best information and the greatest disposition to form an unbiased opinion, the idea is that furnace coke will land at somewhere in the neighborhood of $7, with foundry coke say a dollar per ton higher, and that pig iron will find its level at not far either way from $30 furnace.

It has been decided to call for tenders for the building of the new Lottridge Street School, Hamilton. The approximate cost is to be $300,000.

MR. IRVING TO TORONTO OFFICE

Change Announced in Selling End of the C.M.C. Business in This District

Mr. W. J. Irving has taken over the management of the Toronto sales branch of the Canada Machinery Corporation. He has been with the C.M.C. ever since there was a C.M.C., and he has covered the ground pretty well from Fort William to Sydney. There may be some metal working shops, and there may be an occasional wood working shop that does not know him at sight, but if so the

W. J. IRVING

plant is probably a very new one, and if they stay in business any length of time W. J. will be on their calling list.

Mr. Irving learned his trade as a pattern maker with John Ballantyne at Hespeler, after which he took up the work of a draftsman, finally spending a good deal of his time as a designer. Several of the lines made by the C.M.C. are Mr. Irving's own ideas.

It was almost ten years ago that he went on the road for the firm, and although he has done several other things, selling machine tools has been his chief business.

One well-known machine-tool salesman, speaking to the writer about Mr. Irving, remarked, "I have been up against him several times, and my complaint about him is that I had to be around too early in the morning and too late in the evening to beat him out. I bet dollars to doughnuts that he has taken orders in the early hours of the morning, and in the late hours of the day. I have known him to sign orders on a stump in the field, and I have seen him getting the necessary signature as the train was pulling in at the station."

For the present at least, Mr. Irving will keep his house at Galt, going there for the week-ends. Mr. Irving, like a good many of the rest of us, believes that there are too many people trying to squeeze into Toronto to live comfortably. However, his activities will be taken up entirely now with his work in connection with the Toronto office.

David King, who has had charge of the Toronto office for many years, is retiring from active work to enjoy a well-earned holiday. Mr. King has passed the three score and ten mark and has had a wealth of experience in the selling end of the machinery business.

J. H. QUIRT DIES IN CALIFORNIA

Was One of the Best Known Machinery Salesmen in This and the Northern Districts

The machine tool trade, and many of the older firms in the machine shop and mill business, will regret to hear of the death of J. H. Quirt in Los Angeles, California. He was born in Ogdensburg, 79 years ago, and at the age of 13 with his parents moved to Arthur, Ont. Later he was apprenticed to the blacksmith trade, working at that for some years. Some time after a partnership was formed by Mr. Quirt with James Shand, now superintendent of the Dodge Co., Toronto. This business took in both the machine shop and molding branches. Following this, Mr. Quirt became connected with the A. R. Williams Machinery Co. and spent nearly all his twenty years with them on the road and attending to collections. Speaking of him this week, Mr. T. A. Hollinrake, president of A. R. Williams, said: "He was one of the best known and best liked men in the machinery business. I doubt if there ever was a man who knew the north country better than he." On account of his health he retired from business about seven years ago, moving, with Mrs. Quirt, to Los Angeles, where he resided until his death. He is survived by his wife, in California, and five daughters: Mrs. James Shand of 96 Uxbridge Street, Toronto; Mrs. Walter Findlay, 143 Cottingham Street, Toronto; Mrs. J. Black, Denver, Colorado; Mrs. F. W. Ritchie, Los Angeles, California, and Mrs. W. D. Young, Covina, California.

An experiment in paving is being carried out on the Victoria Bridge across the St. Lawrence at Montreal, and if the method of paving is successful, the entire length of the bridge will be completed next year. Two hundred feet of mastic flooring are being laid, with the object of determining how well it will withstand the weather during the winter. One advantage claimed for the material is that it is fireproof, and will prevent such disasters as the starting of fires caused by the overheating of gasoline and oil from passing automobiles.

CANADIAN MACHINERY
AND
MANUFACTURING NEWS

VOL. XXIV. No. 21 November 18, 1920

Using Turret Lathes in Railroad Shops

The well-managed railroad machine shop has found the value of turret lathes. Their wide range of standard tooling, together with their ease of setting up, makes them a very profitable proposition. Many shops have found it an advantage to concentrate on the making of standardized parts in one shop.

By J. H. MOORE

THE real mechanic of to-day is the man who refuses to sit back and say, "Oh, our present method is good enough." The man who gets ahead is the one that is always on a hunt for a still better method of producing his work. For some time past we have been presenting through our columns different styles of work accomplished on varied classes of machine tools. Not one of these articles has been published with an idea of comparison in mind, but rather with a desire to place before readers how the various firms are producing their products. They themselves can form their own conclusions. By carefully studying these various tool layouts valuable information can be procured which will stand you in good stead on some later occasion when similar problems present themselves.

There is an old saying that it pays to keep posted on all conditions from the foundry to the finished piece, and if more mechanics followed out this advice, production in many lines would soar in consequence. You cannot learn too much about your work, and it is only by studying it carefully that you can master it.

Anyone will, I feel sure, concede the point that the study of motions is a very essential one. There was a time when such an idea was ridiculed, but that time has passed. Henry Ford would never have achieved his present success had not lost motion been reduced to a minimum. Every movement counts if you desire maximum production. Granting that such is the case, how much more so is this true if lost motion is caused through lack of judgment in tool arrangement.

You could take the finest machine tool existent, and mar its possibilities by poor arrangement of tooling. To obtain the best from any machine you must first study your product. Think carefully on what you consider the most economical method of producing such a product, then, having decided on the operations you wish to perform, cast your eyes around and discover the type of machine you require. Manufacturers are rather lucky in these modern days, inasmuch as the makers of various machine tools will, upon request, study their product for them, giving them drawings showing what they believe the best method of producing the same. They even go so far in some cases as to guarantee a certain production, quote both price of machine and tools, or in other words practically solve the production problem for them.

Such service was impossible in the old days, and when a manufacturer can in this way secure such valuable help, it makes his task a much simpler one. All he need do is study the various plans submitted, modify his first ideas if necessary, then choose the equipment he thinks best suited for his own particular requirements.

We will suppose, however, that all this has transpired, that the machines are installed, and the work is being completed as per the submitted plan. Does this mean that the plan is above improvement? Unfortunately such a belief does exist in some plants, but luckily in the majority of shops they are always on the lookout for a shorter method. Improvements to the arrange-

ment of the tooling, and sometimes to the design of the tools, add still a better production record. It is this spirit of eager striving after maximum results that is to be commended. We can well afford to have more of this spirit existent.

One of the finest methods of learning is by a study of the other fellow's method, not in a spirit of critical comparison, but actually in a spirit of seeking for further knowledge. This is why we have been presenting the previous articles dealing with tool layout work, and the present material will be followed up later with an account of other methods of producing work on turret lathes. The practice to follow will be that of some examples of work performed on Warner & Swasey turret lathes, in railroad shops. Although these examples are of work in railroad shops, there are many good points to be obtained from them for use in other classes of manufacture.

Examples of Work Performed

The classes of work going through a good sized railroad shop almost defy description, so that we will be able to give but a few of the great many. At Fig. 1 is seen a typical example of shaft turning on a No. 3A machine. Note the heavy cuts being taken by both turrets simultaneously. As this is a straight turning proposition we will pass on to a further example. Fig. 2 represents a gear blank, being finished on a 2A machine. The tooling used is clearly shown and this photograph is shown more to illustrate the variety of work passing

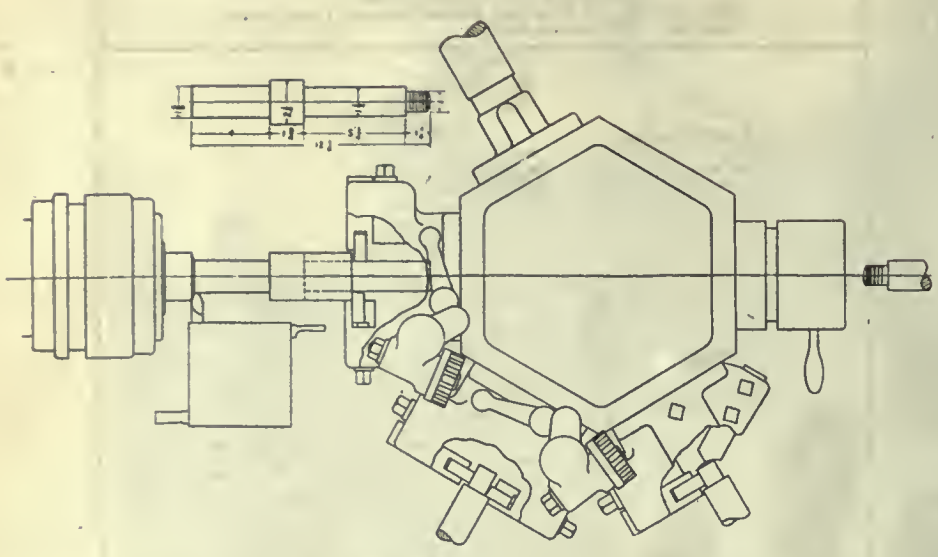

FIG. 7—THIS VIEW SHOWS LAYOUT FOR PINION.

through a railroad shop than for any other reason.

In some railroad shops universal hollow hexagon turret lathes are used to make rivet sets, and one such example is shown at Fig. 3. The work and tools can be clearly seen and require no comment. A prosser being made from the bar is shown at Fig. 4.

The photograph making up the heading of this article depicts a No. 4 universal screw machine busily engaged turning a stud. Both turrets are used simultaneously, and the nature of the work being accomplished can be seen from the pile of studs on the stand alongside of the machine.

Piston Valve Follower

The next example, Fig. 6, illustrates the turning of a piston valve follower in one chucking. To still further discuss this layout in detail, let us refer to the lower part of Fig. 7. Here we see the details of tooling and sequence of operations. The machine used is a No. 3A universal hollow hexagon turret lathe, and the follower is made from cast iron.

At the first station, the work is rough turned to 12⅛-in. diameter, bored 2¼-in., and the piece faced on its 3⅜ diameter surface. At the same time the square turret rough faces the 12⅛-in. and 13 7-16.-in. diameter, and also forms the radius on the 13 7-16-in. diameter.

At the second position the work is finish turned to 12⅛-in. diameter, the 2¼-in. hole is completed, and the 12⅛-in. and 3⅜-in. diameters finish faced. The third station finish faces the 13 7-16-in. diameter portion. The fourth, and last, position used, reams out the 2¼-in. hole.

Further Examples

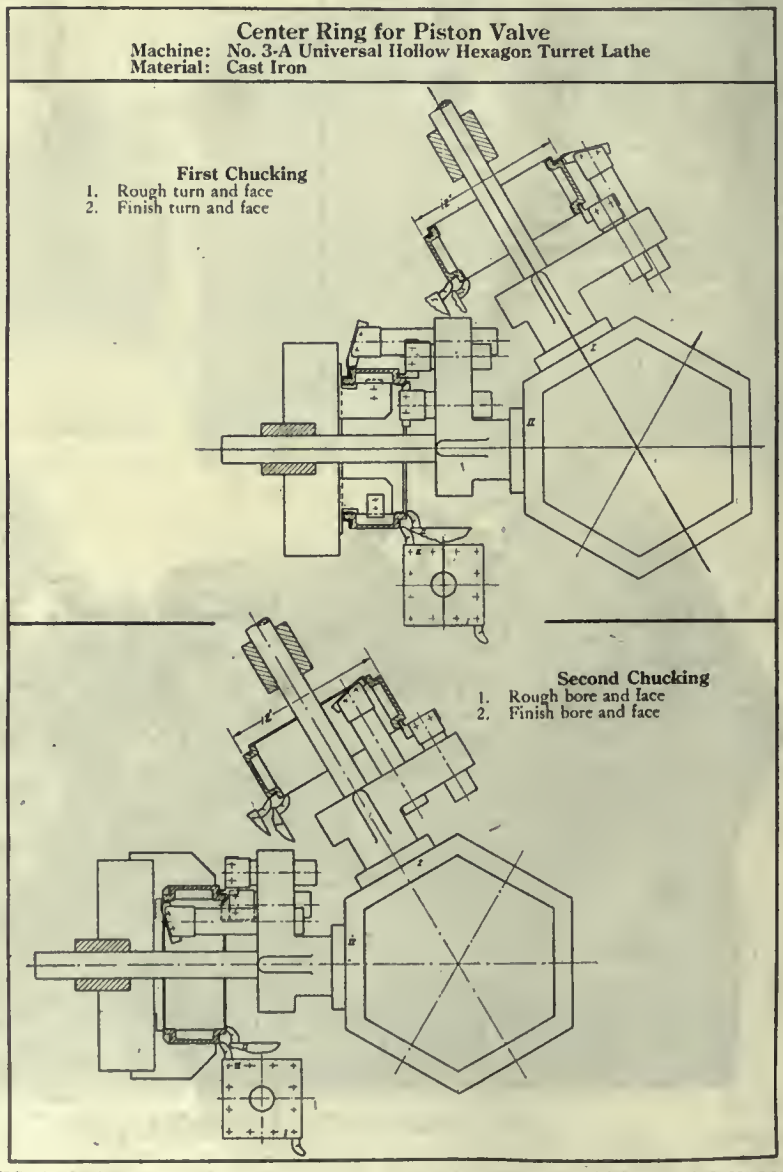
Let us next consider the first portion of Fig. 7. In this case we have a 2½-in. cold rolled steel pinion, the dimensions of which are plainly seen on sketch. Five stations are used in this case, the sequence of operations being as follows: The stock is fed to length and the 1½-in. diameter portion turned for 6½-in. in length. It is now formed ½-in. to the 1⅝-in. diameter, and turned to 1⅜-in. with the square turret.

In the second position (see view on the other page) it is turned 1-in. diameter for the distance of 1¼-in. length, as shown. The third station forms end, the fourth threads the 1-in. diameter portion, and at the fifth position the stock is cut off.

Fig. 8 depicts two chuckings of a washer for an engine truck. The material is open hearth steel, and the sequence of operations follows: At first chucking the first station rough faces and bores out the work, while the second position is used to finish face, turn and chamfer.

The second chucking rough turns, forms, and rough and finish faces. As the dimensions of the piece are given on the sketch, readers can readily form their other proportions.

Two chuckings are also necessary for the centre ring for piston valve shown at Fig. 9. The machine used is a No. 3 universal hollow hexagon lathe, and the material is cast iron. At the first chucking, the initial station is used for rough turning and facing the work. The second station and the last used in this



Center Ring for Piston Valve
Machine: No. 3-A Universal Hollow Hexagon Turret Lathe
Material: Cast Iron
First Chucking

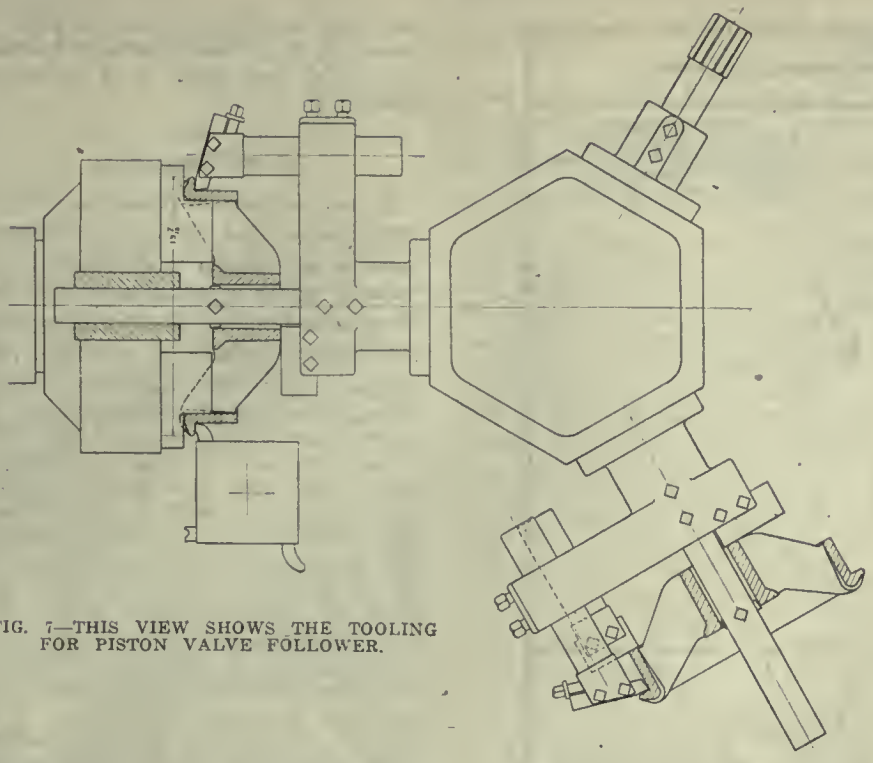

FIG. 7—THIS VIEW SHOWS THE TOOLING FOR PISTON VALVE FOLLOWER.

first chucking, finish turns and faces the work.

The second chucking is clearly noted on the sketch. First the work is rough bored and faced at the portion now turned toward the tools, and in the second position the finish boring and facing is accomplished.

Fig. 10 presents another tool layout of interest. In this case the work is made of open hearth steel and is known as a friction joint for a locomotive trailer truck equalizer. At the first chucking the work is spot centred. The second position rough turns and faces, while the third finish turns and faces the work, aided by the square turret.

The second chucking is shown at bottom portion of sketch. First the work is rough turned and chamfered, then, at position No. 2 it is finish turned. The dimensions of outside diameter of the piece being given, we need state no further as to its other proportions.

The last example, that of Fig. 11, depicts the operations on a certain type of bushing. In this case the machine used is a No. 2 universal hollow hexagon turret lathe, and the bushing is made from a forging.

At the first chucking the operations are as follows. First the six-inch diameter hole is rough bored, and the work is rough faced and turned on its eight-inch diameter. Next the hole is finish bored to six inches and finish faced and turned to its eight-inches diameter.

At the second chucking, the work is, of course, reversed, and the first station rough turns the 8¼-in. diameter, also rough faces. The second position, incidentally the last, finish turns the 8¼-in. diameter, and finish faces and forms the radius in the 6-in. hole.

As stated previously, we are only able to portray a few of the problems possible of solution on this type of lathe. We have in our files, gear blank layouts, friction clutch core work, pulley work, valve bodies, pinion sleeves, pump bodies, differential cases, separator cores, flywheels, and other innumerable examples of work performed. Enough has been shown, however, to illustrate our intentions, and as a concluding remark we might add that, even after you have installed any type of machine, remember to study your tool layout. Keep the layout up to date, and above all do not neglect your tools. Keep them sharp, in good condition, and free from dirt and grease as much as possible.

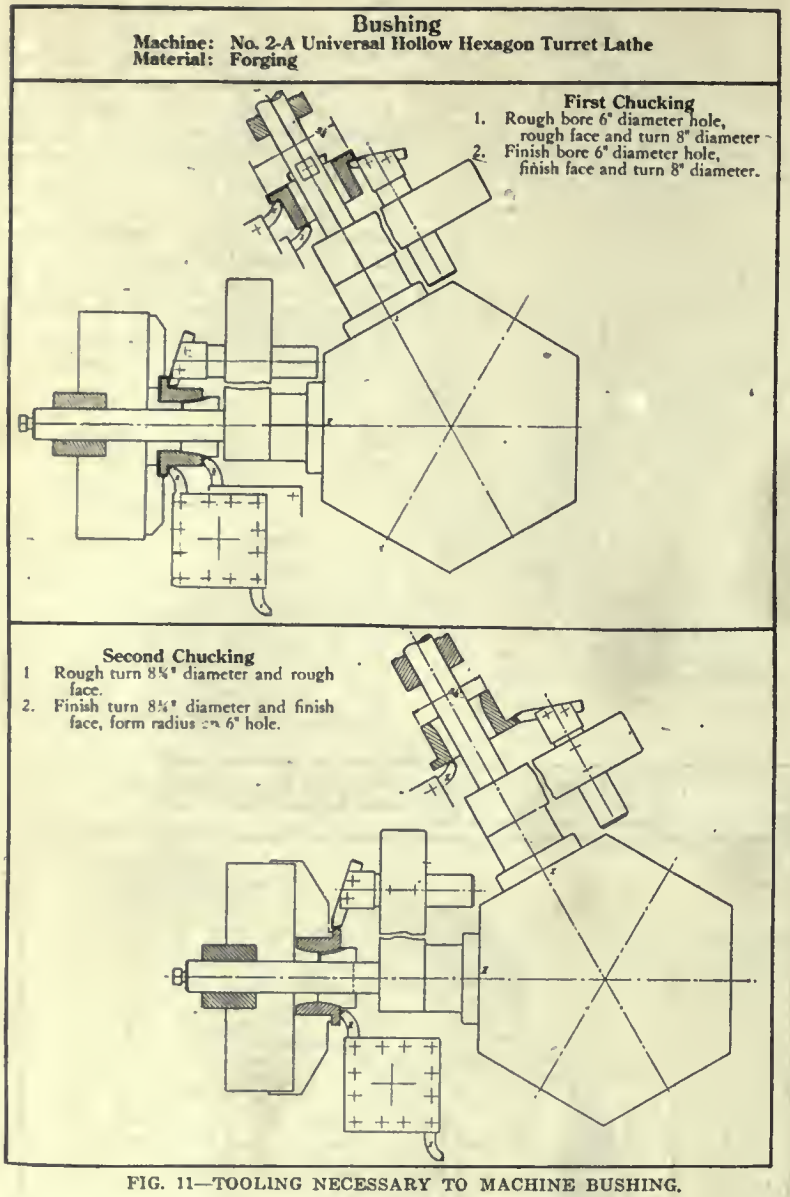
TINNING BLACK IRON SHEETS AND CASTINGS

By W. S. Standiford

In repairing of automobile radiators and for general use in machine shops in emergency work where it is desired to give black iron sheets and objects made out of bar iron or malleable castings a coating of tin, it will be found that by using the process given below any iron or steel object can be given a thick coat-



Bushing
Machine: No. 2-A Universal Hollow Hexagon Turret Lathe
Material: Forging
First Chucking
1. Rough bore 6" diameter hole, rough face and turn 8" diameter
2. Finish bore 6" diameter hole, finish face and turn 8" diameter.
Second Chucking
1 Rough turn 8¼" diameter and rough face.
2. Finish turn 8¼" diameter and finish face, form radius on 6" hole.

FIG. 11—TOOLING NECESSARY TO MACHINE BUSHING.

ing of tin which will protect it from rusting in exposed places for a long time, as a good deposit of metal can be obtained by this method. All the equipment needed is two crocks of suitable size to hold the raw and cut commercial muriatic acids and also an iron ladle to hold the melted tin. The cut acid should be first made by putting small clippings of sheet zinc into the raw muriatic acid until it will dissolve no more. For use it should be diluted with twice the amount of water. In some cases, it is better to use the cut acid without dilution as some muriatic acids seem stronger than others and work quicker.

All objects to be tinned should have the scale and grease removed from their surfaces. This is best done by wiping them with a clean piece of waste and immersing in the raw acid until all scale has disappeared, and the iron turns white. The time of pickling depends upon the strength of the acid and amount of scale. If much pickling is done, the acid will work slower, but it can be used until it is pretty weak and then thrown away and fresh material used. This process allows of coating iron sheets and other articles with not only solder, but with block tin and also lead, if preferred.

After the objects have had their scale removed by immersion in the raw acid, put them into the cut acid for a few moments and shake the surplus off before dipping into the molten tin or solder. This insertion should be done carefully in order to prevent splashing of the hot metal. If the coating is not satisfactory on the first trial, dip article again into the cut acid and put into the hot metal.

The chemical action of the cut acid is this, that the muriatic acid unites with iron or steel, and in so doing leaves a thin deposit of zinc film which facilitates the adherence of the molten metal to iron or steel objects, causing it to stick better than if the ordinary raw acid were used alone. Many shops accumulate small pieces of solder and these can be used for work of this kind, so that the expense is trivial. Even the dross that is skimmed from a ladle of hot solder can be used for this purpose, if there is enough of it, as there is always a certain amount of pure metal in it to do the work.

RUST REMOVER

A new preparation known as "Meno" rust remover and cleanser has recently made its appearance on the market. The inventor of the preparation is a chemist of wide experience, who, realizing that the present methods of removing rust, corrosion, etc., from machines, engines, tools, parts and all metal surfaces requires considerable time, and high labor costs, commenced the task of devising a better and more economical cleansing method. Here is what he claims for it. This preparation is a scientific combination and blending of certain chemical ingredients, which in combination produce an electro-chemical action that rapidly loosens and dissolves rust, corrosion, grease, oil, dirt, carbon, paint or any other foreign substance that is adhering to the metal—irrespective of its age or hardness—and its action automatically ceases when contact between the cleanser and the metal is established. This is as far as it will go, for it will not injure or mar the surface of the metal itself in any way. There are two methods of using the preparation as follows: (1) Apply it to the machine or part with a brush and allow it to remain for a short time, then brush or rub it off and it leaves the metal bright and clean. (2) Mix the preparation in a vat, tank or container with water, then attach the machine or parts to wire or chain so that they will hang in the solution. No further attention is required since the process of cleaning goes on while the parts are immersed. It is stated that the preparation is absolutely safe in every way and that it will not burn or explode. Another point is that it will not cause corrosion or rust to form, in fact, it protects the metal and makes it exempt from corrosive or disintegrating action for a long period after it has been treated by this preparation, and there need be no fear of injury to the most delicate part no matter what metal it is composed of. The preparation is said to be an economical one to use as the same solution may be used many times over, and does not deteriorate or lose its cleansing power. Peter A. Frasse & Co., of 417 Canal Street, New York, are the sole distributors, and are now establishing agencies in various parts of the country.

SCREWDRIVER ATTACHMENTS

Several types of screwdriver attachments for use on air-operated and electric-operated tools, are now being made by the Independent Pneumatic Tool Company of Chicago. The attachments are made in three sizes to fit the different tools manufactured by the company.

Invention is Important Factor to Community

We All Have, More or Less, That Desire to Invent Something, But Even After the Invention is Completed, Certain Procedure Must Be Followed to Ensure Protection.

By W. McFEAT, Patent Attorney, Montreal.

SOME interesting points relating to patents were brought to light in a recent paper presented by the above author at the Canadian Railroad Club in Montreal, and these facts are of importance enough to warrant their reappearance. After all is said and done, we are all inventors at heart, and for this reason the data will be all the more welcome.

I will first tell, says Mr. McFeat, of whence come our laws by virtue of which these patents are granted. I will also try to give my idea of what an important thing for the community invention is. And I will tell upon what conditions Canadian patents of invention may be obtained and maintained. Also how to realize on an invention.

As early as Edward III, in the year 1477, special acts were passed giving relief against monopolies in the form of Letters Patent, under which great restraint of trade was practised for the benefit of the patentee and the Crown. Our old friend, Sir William Blackstone, in his commentaries, first made in a course of lectures at Oxford in 1753, states briefly the condition of affairs before the reign of King James the First of England (1603). Blackstone informs us that during these early years monopolies were granted by the king for the sole buying and selling, making, working or using, of all things whatsoever, and by these Letters Patent manufacturers were restrained from doing that which they had done before. These monopolies had been increased enormously during the reign of Queen Elizabeth. The penalties provided in these early days consisted of heavy fines, with or without the pillory, and for repeating the offense the loss of one ear. We can imagine some of these early infringers sitting in the stocks for days with their ankles locked in the boards and their hands tied behind their backs, where they were made to suffer all manner of indignities by the loafers in the neighborhood. The practice was at the time to raise large sums of money for the use of the Crown and the Government by means of these patents without the slightest advantage to the general public. Amongst the monopolies granted by Letters Patent was the patent granted to the cloth makers of Ipswich, and the patent for playing cards. In neither of which cases was there any pretence of invention.

Up to this time patents had been granted for inventions, besides many more granted, as I have said, for carrying on certain trades or producing various articles or, in fact, importing them from other countries. The monopolies granted under the Tudor Sovereigns became so monstrously oppressive that the Parliament of England prevailed upon James the First in 1621 to consent to a bill which is the celebrated Statute of Monopolies. This Statute of Monopolies of England is the foundation of all modern patent laws. This original law provides for the grant of a monopoly as a reward not only for the benefit that the invention confers upon the public but also for the ingenuity of the first inventor. Consequently if he who first obtained the patent was not the man whose ingenuity first discovered the invention and if proof existed that it could have been taken from a book or other publication, then, although he may have been the first to bring it to the attention of the public and thereby benefit the public by it, he would not be entitled to a monopoly because he was not the first and consequently should not have reward for ingenuity. This was the belief of the progressive branch of the manufacturers of the early part of the seventeenth century as laid down by this initial patent law, and as I have just said, it has formed the basis of all modern patent laws.

> Modern patent laws of different countries vary considerably. Each country aims to obtain the best results for the community. Read how our Canadian law is enacted.

In order to obtain the monopoly granted by Letters Patent of invention it is necessary for a man to rise above the commonplace in whatever art he may be engaged, whether the building of cars, the construction and laying down of track work, the erection of bridges or the manufacture of steel and other metal parts and textile and wooden things, each contributing to the railway and its operation. He must perceive the obstacles to increased or improved production, or greater comfort for the public or the worker, propound the problem the obstacle offers and conceive a remedy. In this way he rises above the commonplace and by seeking a monopoly in the form of a patent upon the device or process conceived he brings himself in a measure before the public and if he is diligent in promoting the result of his ingenuity he will attract the notice of others working in the same art or those who are financially behind this work. From my years of activity in connection with patents of invention I have come to look upon invention as the dramatic, as compared to the commonplace, in the development of the arts. It is this which to my mind directs that attention to the fortunate one to day whose activity makes the first step forward in any art, which brings to him the reward intended by that old law, defined in the Statute of Monopolies back in the early part of the seventeenth century. The dramatic is present in almost all cases where attention is attracted. Take for instance the destruction of lives and buildings in the recent explosion in New York. Our attention was directed to the death of these men and women and the destruction of parts of the buildings, and we all think and talk about it; while just as many lives, just as valuable, are lost, and just as much damage to property takes place each week in the ordinary course of events by street accidents and fires in New York, but they are the commonplace; whereas the explosion was the dramatic. It was the same in the bombing of the City of London by German flying machines when lives were destroyed but not in any greater number than are destroyed in almost an equally short time by street accidents. I wish to impress upon you who are engaged in production that by making a first step forward you are entitled to the notice of those upon whom you depend for advances, and this because of the dramatic nature of the development as compared with the commonplace work.

I have endeavored to bring to you an appreciation of the field that is open to all producers and, I may say, is open particularly to those whose work is the production of that which is necessary to maintain and develop the means of rapid transit.

Patent Laws Vary

The modern patent laws of different countries differ very considerably in their application of the broad principles I have stated. Each country makes its laws with regard to patents of invention, to obtain the best results for the community. In some countries limited publication of the invention there or in fact anywhere in the world makes the invention public property if this publication has not been preceded by the application for a patent. Other countries require that the invention be manufactured to a reasonable extent in that country in proportion to its manufacture abroad. Other countries ignore these requirements and as in the case of the United States, for instance, permit manufacture and sale of the invention in that country for two years before the patent is applied for. In some countries importation of the patented invention is allowed and the patentee may stop all others from importing while he, under his monopoly, may import and thus supply the demand of those countries. These

foreign laws, or the majority of them, had been in existence for many years before the present Canadian patent law came into existence and apparently our law makers adopted in a single law what appeared to be the features of these other laws which are good for Canada. Being Canadian producers we are, of course, interested principally in the Canadian law. From my point of view it has been necessary to emphasize the importance of looking for and overcoming the obstacles to progress in the arts in order that you may appreciate what a patent of invention is; and what I have said regarding the stepping forward in the art is universal, and consequently is essential to the application for letters patent of invention of Canada.

Assuming that a worker in one of the arts has perceived his obstacle and conceived his means for overcoming it and making his forward step, and wishes to obtain the reward to which he is entitled, he is, according to Canadian patent law, permitted to manufacture and sell the invention for one year, wherever he may be, even in the Fiji Islands. If he makes his application for a patent in Canada within that year and is the first to have the ingenuity to make the forward step he is entitled to his patent, provided he can truthfully make oath that his invention has not been in public use or on sale with his consent or allowance for more than one year. He must make this oath in his application. An examination is made in the Patent Office at Ottawa in order to ascertain, if possible, whether he is the first to make the invention and if nothing to the contrary is found the patent is granted. During the time between the filing of the application and the grant of the patent and during the year before the application is filed the inventor may have the invention manufactured wherever he pleases and may import it into Canada without jeopardizing his rights; and he may also continue to import the invention for one year after the patent has been granted. There is provision in the Canadian Act for an extension of this year but the Commissioner of Patents must be satisfied that the further importation after the first year will be for the benefit of the community and that it will lead to manufacture in Canada, otherwise he will not grant any extension. With regard to the manufacture of the invention in Canada—as the patent issues it is subject to a provision of the Patent Act which requires that manufacture of the invention be commenced in Canada within two years after the date of grant of the patent and after such commencement the manufacture must be continuously carried on, even if it has been commenced before the application is filed. Failing commencement to manufacture, and continuously manufacture, the patent is forfeited and all rights and privileges thereby granted cease. The law is very strict in this regard and the Privy Council has stated that there is no room for interpretation, its reading being perfectly clear. There is no doubt about this as the section of the law covering manufacture reads thus:

"Such patent and all the rights and privileges thereby granted shall cease and determine and the patent shall be null and void at the end of two years from the date thereof unless the patentee or his legal representative within that period or an authorized extension thereof commence and after such commencement thereafter continuously carry on in Canada the construction or manufacture of the invention patented, in such a manner that any person desiring to use it may obtain it or cause it to be made for him at a reasonable price, at some manufactory or establishment for making or constructing it in Canada."

Before 1903 it was the common belief amongst manufacturers who took advantage of patents of invention to improve their business that this law could be interpreted to mean that manufacture need not be carried on unless there was a bona fide demand; but in 1903 this section of the law was tried out and our Supreme Court decided that the law was clear and that there was no room for interpretation, this decision being upheld by the Privy Council. The result of this decision was that the owners of a large majority of Canadian patents found that their monopolies had been forfeited, and they got after our law makers and made them pass what is known as the Remedial Act, which revived all the patents forfeited, upon the condition that manufacture should forthwith be commenced. But a difficulty presented itself. How could the inventor of a grain elevator or a railway bridge or a round house commence to manufacture his invention and continuously carry on the manufacture or erection if the Government or the railways could not be made to see sufficient advantage to give an order? This was taken care of in the Remedial Act by providing for relief from the restrictions of the law regarding manufacture, and provision was made for an order to be granted by the Commission relieving such patent from the restrictions of the law and making the owner responsible for the manufacture of the invention in Canada so that the reasonable requirements of the public in reference to the invention would be satisfied. This may be done by granting a license, and any one interested in the art to which the invention appertains may go before the Commissioner, and upon proving to him that the owner of the patent either by neglect or wilfully monopolizing the invention has prevented him from obtaining it, may obtain an order from the Commissioner on the owner of the patent compelling him to grant a license to the sufferer. The owner of the patent, however, may be heard and if he proves that the alleged sufferer is not in the true sense of the word "of the public," but, on the other hand, a competitor of the owner of the patent in the supply of the invention to meet the requirements of the public, then it may be expected that the Commissioner will deny the petition for the license and the alleged sufferer will be compelled to send his customers to the owner of the patent. If, however, it appears to the Commissioner that the owner of the patent is exercising his monopoly in the restraint of trade or is otherwise not satisfying the reasonable requirement of the public in reference to the invention, then he will order the owner of the patent to grant the license; and if the license so ordered is not granted within three months, then the patent will be forfeited. I may draw attention here to the fact that the spirit of Canadian patent law is that manufacture for Canada's need must be carried on in Canada. This is further demonstrated in another condition upon which the Canadian patent is granted, namely: the limit of time set for importation of the invention. According to law if the owner of a patent or his licensee or an assignee of a share in the patent, imports the patented invention or any machine or car or locomotive or frog members, switchstand or anything else containing the invention after the expiration of one year from the grant of the patent, then the patent shall be void as to the interest of the person importing it. For instance, supposing John Jones has a patent on a detail structural part for the reinforcement of the roof of a box car and he grants a license to a car dealer who has the cars built in the United States and equipped with the patented structural detail. These cars are imported by him into Canada say one year and three months after the issue of the Canadian patent and sold to a railway company. In this case the patent is forfeited because of this importation, but it is only forfeited as to the interest of this dealer and consequently his license is lost; and if John Jones has had nothing whatever to do with and no knowledge of this importation, then his patent is not affected. On the other hand, if John Jones has knowledge of this transaction of his licensee, which may be proved by the obtaining of license fees for the cars sold, then he has connived and because of this connivance, not having prevented the licensee from importing, John Jones also forfeits his rights and the patent itself becomes null and void and the invention is thereby free to be used by the general public. There is an erroneous belief that the Canadian patent law does not apply to railway inventions and that cars and locomotives and railway stock generally may be built or equipped in the United States according to or with inventions patented in Canada and imported into Canada without jeopardizing the Canadian patent rights. In fact, I have heard it stated positively by lawyers in the United States that the Canadian Patent Act makes an excep-

tion of railway cars. They base their contention on a section of the Canadian Act which makes an exception of inventions in any foreign ship or vessel touching our shores. The law, however, is not any more open to interpretation than the law governing manufacture, because its wording is simple and very clear. This interesting law reads as follows:

"No patent shall extend to prevent the use of any invention in any foreign ship or vessel, if such invention is not so used for the manufacture of any goods to be vended within or exported from Canada."

There is nothing equivocal in these words. It is clear that the law relates to any foreign ship or vessel and it does not require a legal luminary to make our learned judges understand what is meant by the words "foreign ship or vessel." Anyone having a rudimentary knowledge of the English language knows that a foreign ship or vessel cannot be a railroad car on rails and I have no doubt that when the time comes for a court of competent jurisdiction to decide what this law means that there will be no hesitation in deciding that it has reference to ships or vessels or in other words steam ships or sailing vessels coming from foreign ports to the ports of Canada, and that it is limited strictly to these ships or vessels and cannot be extended in its scope to include railway rolling stock. There is considerable controversy about this, but our friends across the border who persist in ignoring our laws governing manufacture and importation cannot have a conviction of the justice of their cause, when they argue that the railway rolling stock is a foreign ship or vessel, otherwise they would take the steps available to obtain a decision on the question by our courts.

Interesting Phase

Another phase of the Canadian patent law which I should bring to your attention is the fact, not before mentioned, that an applicant must swear that his invention has not been in public use or on sale for more than one year with his knowledge or consent, before his application for Canadian patent. When the invention is conceived and developed in Canada it is not likely that the inventor will sacrifice his rights. The case is different with the inventor who conceives and develops his invention in the United States, because if he takes advantage of the United States law and puts the invention on the market for almost two years before he applies for his United States patent, then he will have forfeited his Canadian rights even before he applies for his United States patent. In many cases this is done inadvertently, the United States inventor being ignorant of the Canadian law, and after his United States patent application has been allowed and he finds his invention is a money-maker in the United States he turns his eyes to Canada and seeks advice from his attorney regarding Canadian patent rights. The grant of a Canadian patent is also subject to the filing of the application within one year from the date of the issue of the first foreign patent for the same invention. It has happened in cases which have come before me for investigation that the United States inventor has not filed his Canadian application until sometimes five or six years after the first public use or offer for sale of the invention in the United States. This comes about in this way, he makes his forward step in the art and in order to ascertain if the idea is practical and if practical whether there is any money in it he gets some made and places them on the market, or if it is a comparatively large plant interests a railway or other large corporation by offering the invention by means of blue prints. A bridge, of course, could not be built and then offered for sale, so the inventor would bring his drawings to the bridge department of the railroad and submit his idea. Whether the bridge is built at that time or not the inventor must file his application for a Canadian patent within twelve months from the date he offers it for sale. If he does not offer it for sale but constructs the invention in private and then puts it in use where it may be seen by the public, a new headlight for instance, he must file his application for a Canadian patent within twelve months from the day of first public use. Our friend, however, usually has no knowledge of this condition of grant of the Canadian patent and may have been told, as has too frequently happened to my knowledge, that the Canadian patent may be obtained by filing an application within twelve months after the issue of the corresponding United States patent. With this idea in the United States inventor's mind he proceeds with his United States work and after having satisfied himself that the idea is practical and a money-maker, he files application for United States patent. It is a well known fact that an application for United States patent takes all the way from six months to six years and longer to get through the Patent Office. Assuming that this inventor's patent issues in the United States two years from the date of its filing and it is filed one year and eleven months after his first offer for sale or public use after the issue of his United States patent and within a year he files his application for a Canadian patent, ignoring the statement in the petition that the invention has not been in public use or on sale with his consent or allowance for more than one year previous to his application for a patent in Canada, then his application is void as is also his patent if granted. Sometimes these inventors have been advised that what is meant by this statement is public use or offer for sale in Canada only, and that public use or offer for sale outside of Canada does not affect in any way the Canadian rights. This is not so. The Canadian application must be filed within one year from whichever is the earliest date, the offer for sale, public use or issue of the foreign patent. For this reason a large proportion of the inventions which have been conceived and developed in the United States and form the subject of Canadian patents have been dedicated to the public of Canada before the filing of the application for the Canadian patent and consequently all these Canadian papers are not worth the paper on which they are written.

Contrary to common belief, invention is a simple process of the mind and it may be interesting for me to give some examples:

It was found that in casting metal rotary motion would result in throwing out the dross. This was due to an understood law of nature, an operation of centrifugal force, the advantage being that, for instance, rollers with more perfect surfaces could be cast. This was known and it was the practice to stir or otherwise cause the metal to rotate, it being an understood law of nature that rotary motion would so result, as an operation of centrifugal force. The point I wish to convey is that those skilled in the art of casting metal knew that by imparting a rotary motion to the molten metal, the dross would be caused to separate; and the problem before all molders was to produce the motion more conveniently and uniformly than by stirring the liquid metal, as soup would be stirred by a spoon in a pot. The commonplace workers in the art employed any kind of implement suitable for the purpose and overlooked the inconvenience and want of uniformity, but a man named James Harley, a workman in a foundry in Pittsburgh, conceived the idea in 1834 that he could make the metal revolve by injecting it into a mould tangentially. He obtained a patent for it and the patent was upheld. Another interesting simple invention was made by Asa Whitney, of Philadelphia, in 1848. He discovered that hardness once given to iron will not be destroyed or seriously impaired by the immediate reheating of the iron and its subsequent very slow cooling. What he discovered was simply a law of nature and as such could not be patented, but he went further and worked out a process consisting in taking the wheels from the moulds very soon after their rims were chilled and in putting them immediately into a chamber which had previously been heated about as hot as the heat of the wheels when put into the chamber and thereupon raising the temperature of all parts of the interior of the chamber or furnace and its contents to an equally high point, and finally in causing all parts of the wheel to cool with equal slowness. Mr. Whitney obtained a patent for his process and his patent was upheld. In each of these cases the invention consisted in simply applying a well known law of nature to a certain

art and the simplicity resides in the fact that once the obstacle is seen and the problem is lined up there is usually very little difficulty for the trained mind to conceive an idea by which the obstacle may be overcome and a step forward made in the art.

Another Example

Let us take as an example an invention which has been produced in Montreal and assume that the inventor, contrary to the usual practice of inventors in the Province of Quebec, wishes to obtain a reward for his invention. He makes his application for a patent within one year from first public use, and if he has not already commenced to use his invention he introduces it to the trade. Of course, if he has a backer he may be relieved of the necessity of introducing the invention to the trade by his personal effort, but the case I am taking as an example is one where the inventor has no backing. I have known cases where the inventor has succeeded by first having his invention manufactured, then obtaining a price from the manufacturer, after which he approaches the jobber, the retail dealer or the consumer, turns over any order he obtains to the manufacturer to be filled at a price stipulated in a contract, his sale price being, of course, in advance of this. A demand may be created this way, having for its purpose to induce the manufacturer, jobber, or retailer to become interested. There are many other ways of course to realize on inventions.

There is a great advantage to employers from patents upon inventions developed by their employees. This is so whether the patents are held by the employer or employee, and the advantage is due to the mere fact of the patent being obtained which usually proves a bar to a competitor obtaining a patent by which he may hold up his employer.

With regard to contracts many of our prominent concerns make contracts purporting to be based upon patents of invention but when investigated and analyzed prove to be a guarantee of profit to some outsider which could not be exacted except for the contract itself. Business troubles of this nature can usually be foreseen and avoided by a careful investigation of the antecedents of the patents involved before the contract is signed.

In conclusion I would say that the individual granted a monopoly on an invention by the Patent Laws of Canada is afforded a protection which is not equalled by the patent laws of any other country, and he is encouraged to explain his invention to those engaged in the same kind of work. His patent of invention is a property of which he cannot be despoiled by any Act of Parliament either Federal or Provincial. His right is not excelled in point of dignity by any other property right, and equals the right of authors in their copyrighted works. Furthermore the benefits he confers are greater than those he receives, for he confers upon his community a means of either lessening toil or of increasing comfort. It is also an indestructible heritage of posterity. In return he receives a limited and conditional monopoly from the Dominion of Canada the grant of which costs neither the Government nor the people anything. And his reward shall be all the more sure because it is for creating things unknown before, the creation of which is a step forward in the commercial or scientific life of this country.

HE WANTED A LITTLE TIME TO GATHER MONEY AND GOT IT

IN these days of financing, men are doing things at times because they have to, and not because they want to. Here is a story related to Canadian Machinery to-day as illustrating the effect of tight money on some lines:

"A friend of mine," stated our informant, "had a shipment of parts coming in amounting to about $25,000, and he had secured these on the understanding that it was to be practically a cash deal. The bargain was made some time ago, when it was a great deal easier to finance than it is now. He was in need of the parts to finish up work that he had under way in his factory, but to tell the truth he did not have the $25,000, and there was not one chance in a thousand of the bank helping him to get it, or any portion of the amount. Without the parts the stuff he had in the process of manufacture would be no use at all. So there he was.

He Started Something

"Well, this friend of mine is somewhat of the plunger type, and it is a hard thing to get him stopped entirely. So he wired at once to cancel the order and stop shipment of all goods ordered by him. He knew quite well that the parts made up would be of no value to the firm that had made them for resale, and the chances were they would protest against any such thing as a cancellation, although there was no mention made of such a thing in the sale. The expected happened, and it was not many hours before a wire came back to the effect that the order would not be cancelled. My friend was highly pleased to hear this because he wanted the parts. So there started a letter-writing contest that lasted for some days that ran on into weeks. In the meantime he was busy digging up money. His proposition is all right and safe enough, but that does not seem to make much difference just now when it comes to raising cash. At the end of three weeks he had $18,000 in the bank against the shipment, and in order to save further legal trouble the man who was making the parts agreed to ship on payment of $15,000 and give him thirty days for the balance. Well, that was exactly what he wanted—nothing more than a little time, and he got it and made good use of it.

"I claim," continued our informant, "that my friend's nerve was a good thing for all concerned. It was a good thing for the man who had the goods ready to ship to him, and who was moved to the point of legal action by his threat of cancellation. It was a good thing for the men in those two plants that he did just what he did. It saved the situation, and I know of a good many men who, if they faced such a problem, would simply be licked. It all goes to show that a certain amount of daring—and shall I say nerve as well?—can get people out of trouble as well as into it."

Now on Canadian Market.—The Magic Leather Treatment Co., Detroit, have opened a warehouse in Windsor, Ont., whence they will cover the requirements of the Canadian market, thus eliminating details of exchange and customs duty. This product will thus be placed on the Canadian market for the first time. It is a purely neatsfoot oil proposition. A high viscosity is secured through a scientific chemical process, so that when the treatment (it is not a dressing) is stuffed into the belt it becomes a good substitute for rubber, making the belt impervious to all shop or climatic conditions. It is alike applicable to leather, canvas, and manila rope and, it is claimed, increases the life of the belt four times. It is especially useful for belts in bakeries, dairies, confectionery and other food manufactures, where odorless, sanitary conditions are necessary. Mr. J. Horrocks will have charge of the Windsor office and is the chief selling agent for Canada.

NEW DISAPPEARING WINDOW SHUTTER

Continued from Page 457

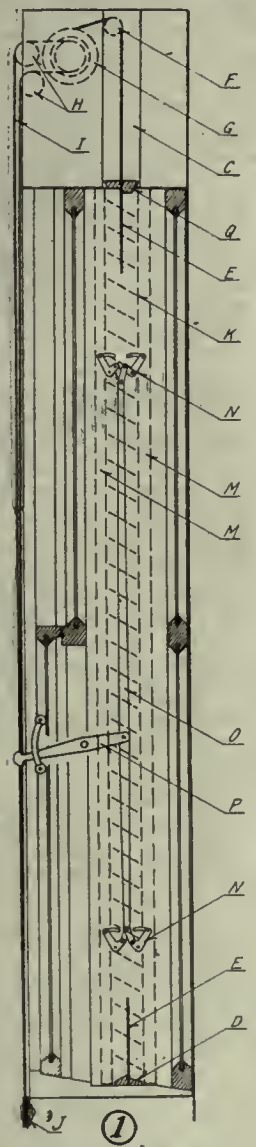
by the bar Q resting on the bevelled portion of the frame.

Fig. 1 is a skeleton view of the window, with shutter lowered and before closing. Fig. 2 is a detail of shutter completely closed and slats K locked by lateral movement of the vertical strips M. Fig. 4 illustrates the mechanism for moving the strips to and from the shutter slats. Two views of the shutter and the elevating supporting bar are shown in Fig. 5. A partial section of the upper chamber is illustrated in Fig. 6, and a general cross section of one side is shown in Fig. 7. Negotiations are now progressing for the formation of a company to manufacture this appliance.

New Design of Disappearing Window Shutter

By J. H. RODGERS

THE accompanying drawings illustrate the general construction features of a new design of window shutter intended for use on office buildings, factories and private residences. This device has been invented by Charles A. Bull, of Montreal. It is claimed that the shutter can be constructed to conform to existing windows, or as is primarily intended, may be incorporated into a window casing, thus forming part of

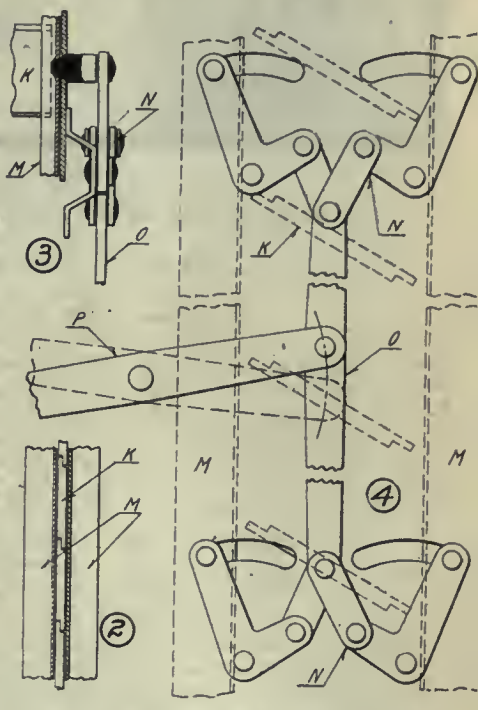


the whole. When not in use the shutter is elevated by means of cables and located in a chamber attached to the upper framework of the window. When in a closed position the shutters are held firmly closed by the pressure of the side strips bearing against either side and at each end of the shutter.

In the design shown the construction calls for the placing of the shutter within the space between the movable windows and the storm sash. The design may be modified to suit any particular style of casing. Provision has likewise been made for adequate fire protection in the automatic closing of the shutter, consequently eliminating the creation of draft for feeding the flames.

In the sketch shown A represents the sheet steel frame of the window. B is the upper portion in which is the chamber C for retaining the shutters when same are not in use. The lower or elevating bar D is supported by a cable E —one on either side. This cable passes over the pulley F, and is wound upon the spool G. On the same shaft that carries the winding spool is a small drive pulley around which passes the control cable or link chain I, this cable passing over the guide pulleys H and thence in a downward direction in front of the window frame to the pulley J. This pulley is fitted to an adjustable bracket for regulating the tension of the operating cable. The shutter slats K are suspended an equal distance apart and the end trunnions are slightly off-centre so that they automatically tilt into an inclined position when lowered from the upper retaining chamber.

When completely lowered the piece D rests upon the sill and the vertical locking strips M are pressed against either side by the movement of the link mechanism N, operated by the connecting rod O, which is moved in a vertical direction by means of the lever P, the outer end of this lever protruding through the casing of the window frame and within easy reach of a person in the room.



VIEW SHOWS THE ATTACHMENT IN DETAIL.

A ratchet bracket is provided for locking the shutters in a closed position. The edges of the slats are overlapped to exclude the air and light and prevent the passage of rain when storm windows are not in place, or when shutters are located on the extreme outside of the frame. When in a closed position the opening to the upper chamber is blocked

THIS SHOWS VARIOUS DETAILS OF SHUTTER. REFER TO TEXT FOR EXPLANATION.

WELDING AND CUTTING

Lessons of the A.B.C. of Good Welding

This Material Deals With the Ideals of the Welding School

By W. B. PERDUE

SEVERAL years ago the prospective purchaser of a welding torch hung out a shingle with the stereotyped sign "Welding and Brazing" upon it. Many times the shingle was displayed before the torch arrived, so that several jobs might be waiting long before the new welder figured out just where to connect the hose and just how he could connect up all the tips which came with the outfit at one and the same time.

To him the torch and its seemingly intricate regulators were a thing of mystery—he had never seen one before—and you can wager your last nickel that when he once succeeded in getting the regulator pressures adjusted so as to get some definite action that he never moved them. There they stayed until the terrific impact of the full cylinder pressure pounding down on the seat each time the tank was opened rendered the seats useless. Then, of course, the company who sold them came in for a "good hauling over the coals."

Recently, however, much of the injury to the good name of the welding industry has been retrieved by progressive and up-to-the-minute welding concerns who have brought the merits of welding before the public so forcibly that the trade schools throughout the country are devoting more interest to this trade than to many others.

Scientific Interest Justified

When he catalogues the various subjects in which the welder must be versed, or of which at least a working knowledge is required, the college professor or the dean of the engineering school is well justified in giving the art of welding a place in the sunlight. It is gratifying to see this awakening of scientific interest and the great amount of research work that is at present being conducted, and more especially the demand by many of the large users of welding for engineers with sufficient knowledge of the process to determine by visual inspection of a weld whether or not it is sound and has been executed by a skilled operator.

A thorough study of the requirements necessary to secure complete and proper penetration coupled with the ability to properly execute the work oneself will enable the inspector to pass upon welding more rapidly than upon the work of any other skilled mechanic. The fact that the author in addition to his other duties inspects more than one thousand pressure containers per month, and in the event of defective work not only replaces the container but bears all expenses that have been entailed by the purchaser, should convince the skeptic that this work can be done with great rapidity and that the percentage of defects that can escape the trained eye is almost negligible.

The decline of the apprenticeship system of recent years and the demand for skilled workers during the war led many inexperienced laborers to represent themselves as skilled mechanics and to secure employment as machinists, carpenters, toolmakers and what not. The scarcity of labor at that period enabled many of these to hold positions for a few days and thereby to secure some valuable schooling at the hands of the foreman who was compelled to "turn orders out." In many machine shops there were mechanics detailed to set and grind tools for "operatives" who knew nothing more than "stop the machine if something goes wrong."

After drifting from one shop to another, and devoting his leisure to study in the public library it often happened that the "operative" learned enough to enable him to hold down a permanent job. The field of the modern trade school is to save the employer the hundreds of dollars' worth of scrapped material resulting from the work of inexperienced operatives, or in other words, to form a link between capital and labor.

Welders Require Skillful Training

To the uninitiated the art of welding appears simple. The beginner or the helper who has watched his welder for many months is very prone to remark that he has noticed how clumsy others have been in their work and that he is confident that he can master the entire process in a very few days. Others quite as firmly believe that they can master the art by home study and self instruction. We do not wish to go on record as making the statement that such procedure is impossible, but we do state that the cost of any materials required to master the art under such conditions would by far exceed the cost of tuition and expenses in a school of recognized merit where the help of one or more expert instructors is at all times available.

The average student is inclined to be over-anxious to get to the point where torch manipulation and practice is no longer necessary. The man who cannot execute a bronze weld with a ripple of absolute regularity and cannot continue to move his torch hand without interruption while his left carries the welding rod after more flux needs more practice. Welding looks simple, but appearances often deceive. It cannot be learned in a short time by the average man who is readily discouraged. After the third or fourth unsuccessful attempt to execute a neat ripple he is very likely to give up.

This is fortunate rather than unfortunate. Men who are so readily put aside would not become an ornament to the profession. They would not have the patience to carefully study what others are doing or attempting to do, and to keep themselves abreast the times through the medium of their trade journals. On this particular subject a well-known authority on training welders states: "It is essential that he (the student) should familiarize himself with the physical and chemical laws embraced in the welding and cutting business." Such knowledge will instil great respect for the powers that he controls and afford the necessary resourcefulness to overcome difficulties that may be encountered. The more knowledge he has at his command the greater will be his respect for his trade and his desire to assist in its upbuilding.

An ignorant workman becomes a mere machine, able to turn out sound welds only under such conditions as have been taught him by others. The calloused villain of the movie screen who is made to

AUTHOR'S NOTE.—The increasing number of inquiries from high schools and trade schools which teach welding, as well as large concerns who are unable to secure competent help and must therefore train their own men, necessitates a more detailed reply than can be given in an ordinary letter. Hence this article. The regular routine of instruction will be resumed next issue. The principles given are not all original with the author, but are such as have been found most successful in welding schools throughout the entire country.

exclaim, "—— them, they are nothing more to me than machines," may have been nearer to the truth than we like to imagine. Yet we have the consolation that it depends entirely upon the mechanic himself whether he does the work and receives the pay of a "machine" or uses his thinking powers to lift himself into the class of the thinkers and doers.

The more highly trained and intelligent workman may be no better welder on common every-day routine and repetition work, but his broader knowledge of the principles on which his trade is founded will make him more resourceful and consequently better able to cope with new problems and to handle high-class work that may be a little out of the ordinary. Hence, the welding school must not stop with the manual training of the welder and such lectures and lessons as will enable him to gain a general notion of the physical and chemical laws which govern his work, but there should be a decided effort to train each individual student to think for himself.

Honesty Above All Things Else

The first thought to a student of any trade school should be the necessity of absolute honesty both with himself and his employer. He is old enough to realize that any neglect to properly assimilate the lessons given him for home study will but delay his progress and that it is up to himself to devote enough time to the home study work outlined, to enable him to keep ahead of schedule, and to be prepared at each session for the work to be done that particular day.

He should be taught principles of welding so thoroughly that he will be able to explain and illustrate to the instructor just what is required before attempting any new work. With a thorough understanding of what he desires to accomplish he is able to draw a mental picture of the work to be accomplished and from this picture to develop the ideal with practice. He must learn to test his own welds, discover defects in his own and the work of others by visual inspection; in other words, he must eventually become his own critic and get into that state of mind that will not permit him to turn out anything that may be unsound or of slovenly appearance.

Short Class Periods Essential

As previously stated, the periods of instruction should be brief. This not only materially lessens the cost of gases used (the one big item of expense in training welders) but gives the student a change from physical exercise with the torch to mental exercise devoted to home study, and (at such periods as the student can command) to muscular training with a dummy torch under a light in his own home. (This dummy can be constructed from an old broom handle or other short stick with a nail driven through near the end to resemble the angle of the tip. The shadow of this point is made to describe the motion to be imparted to the tip of the torch.)

It has been found by common experience that any new art can be more quickly imparted to the adult mind by means of a short lesson given daily than by means of continuous instruction. Some of the best operatives of the Standard Oil Company (records of Richmond, California, plant) are those who were trained in the company's own shop by attendance at their war-time night school three evenings per week. The same also holds good in training adults to operate motor vehicles. For example, the owner of a new automobile can be taught driving and considerable of the care of the machine in ten daily periods of one hour each. To try to impart the same instruction in one ten-hour session would be rank folly and no auto school in the country would make the attempt.

The operation of any mechanical device requires not brain work as is commonly assumed, but the training of the subconscious mind which is directly connected with the spinal column. Short lessons repeated at frequent intervals have been found to develop the subconscious mind most rapidly—in fact, more rapidly than when the lesson is drawn out to the point where fatigue causes the student to become nervous and to lose poise and self-control.

No operative is competent to operate a torch or other device requiring constant attention until his subconscious mind is so developed as to relieve the brain of all detail. If the driver of an auto must brain-think which way to turn the steering wheel when he turns a corner he is liable to make a mistake and come to grief. The untrained driver who fears a collision with a tree a hundred feet in front of his car will invariably effect such a collision. But when his subconscious instinct has been trained to operate the car any necessary movement of the wheel or gears is made before the brain has time to think.

In the training of welders it is necessary and essential to encourage home practice to cause the various details of operation to be passed on to the subconscious mind as rapidly as possible. "Whistle a waltz and move the torch back and forth across the weld." Whistling relieves the mind of worry and enables the instinct to grasp the details of operation more quickly. If the operator must brain-think to move the torch he cannot give proper attention to other details essential to the making of a sound weld. In fact, one can concentrate the brain on but one idea at any one time —the subconscious mind can carry out a dozen details simultaneously. Therefore, the welder must have the training that leaves him entirely free to watch the welding, and that training is possible only when he has completed a wise course of instruction that has corrected his faults, imparted sound principles, given him a correct perspective of his work and taught him to think for himself.

PRODUCTION METHODS FOR WORKING LEAD

When casting ingots of lead or other metals of a similar nature, where rapid handling is necessary, the following method is advised. In the molten metal a centrifugal pump is situated. The method of driving is by a vertical shaft, which in turn is driven by a set of bevel gears driven from the horizontal shaft. From the pump a pipe leads out to a revolving fixture. The control of the lead is taken care of by the valve, which necessarily has to be kept hot by a flame from a burner so that the metal will not chill and stick the valve. The valve must be constructed of cast iron and the pump must have iron bearings, the shaft through which must be a "sloppy" fit.

Another instance is where one desires to cast small parts in quantities and the weight of them must conform to certain limits. This can be accomplished by the use of a quantity valve which I have shown in the sketch? This valve sits immersed in the molten metal and must also be constructed of a non-adhering material—cast iron. The stem of the valve has a chamber in it that holds just the proper amount of metal. It must be a taper-seated valve of course, and held in place by lock nuts at bottom. These can be of steel. The valve, as shown in sketch, is in the discharging position, having been turned 180 degrees from the loading position. In order that the valve will properly discharge, it is necessary that no vacuum be caused to retard the discharge of the metal. A vent pipe A is necessary to accomplish this, but admittance of air will cause the formation of oxidized refuse in the chamber, which will cause a variation in weight of the mold.

If the intake of this vent pipe is situated where it will draw in the flame from the burner beneath the tank of metal, no oxidization will take place and the weight will be uniform. The discharge B leads to a fixture of a revolving type where the molds are situated.

AIR TRIP FOR POWER PRESSES

A pneumatic device for the tripping of power presses and other machinery where difficulty is often experienced in reaching the starting treadle when handling the work has been brought out by the Lovejoy Tool Works of Springfield, Vt. The appliance consists of a cylinder and valve, and is secured to the frame of the press in such a position that the connection at the top of the piston may be bolted to the trip lever of the press. When the air is turned on the piston is raised and the trip mechanism is released. The piston and valve are brought back to the idle position by means of two springs. The valve may be operated from any position about the machine by the use of a cord that is held in the hands of the operator.

DEVELOPMENTS IN SHOP EQUIPMENT

RING TABLE

READERS will no doubt remember the article we had in our October 7th issue dealing with a Newton continuous miller. This present material deals with another type of miller produced by this firm and which has certain features well worth going into.

Figs. 1 and 2 illustrate this machine. The view shown at Fig. 1 depicts the roughing spindles, while Fig. 2 illustrates the finishing spindle. It will be observed that the same fundamentals of construction referred to in previous machine form a part of this one.

The base is circular in form, providing a central taper column. The table casting is fitted to the central taper column of the base, and in addition is provided with an annular bearing close to the periphery of the table. The cross rail and the central upright are made in one piece so as to reduce even on this large machine the number of bolted connections. The table is 84 inches in diameter and the depth from the annular bearing to the top of the table is 12 inches. The least diameter of the taper fit between base column and table is 36 inches. Table is provided with a finished hub 42 inches in dia neter to assist in locating jigs on the table. The central column is bolted and keyed to the base and the cross rail is fitted in the front with one housing containing two spindles for the roughing cut. On the back of the cross rail and at a distance of 42 inches is a similar housing carrying a single spindle for the finishing cut.

Roughing and Finishing

You will observe that both the housings for the roughing and finishing spindles can be positioned on the cross rail so that where machine is used for a variety of work the spindles can be positioned to the most economical location of the jigs upon the table so that the jigs can be made with the least angularity and the least loss of space between them. The outer end of the cross rail is supported by a column which is bolted and doweled to the base as well as the cross rail.

Drive is on the top of the machine, motor gearing to a jackshaft, and at the extreme outer end of the cross rail will be noticed a box which is used to transmit the motion from the jackshaft to the roughing and finishing spindles. This permits of a provision for varying the rotative speed of the spindles independently of each other, and whilst the speed is predetermined and fixed, this provision permits of changing the speeds when the grade of material or size of cutters is changed.

The rotative movement of the table is controlled by a fixed feed which is predetermined, but provision is supplied by which this rate of rotation can be changed to suit any change in the grade of material. There is not, however, any possibility of the operator increasing or decreasing the production of the machine as the rotative speed has been pre-determined, which means that a given number of stations per hour must pass the loading station, hence that number of pieces must be machined. The table itself is rotated by a herringbone gear 81 inches in diameter. Each of the spindles is provided with an individual adjustment for setting the cutters to gauges.

Different sizes of housings providing varying centres between the roughing spindles are used, depending upon the dimensions of the work. Generally, however, these centres are either 12 or 14 inches. Both spindles are rotated inward or clockwise on the left-hand spindle and counter clockwise on the right-hand spindle. With the distance of 42 inches from the centre of the roughing cutters to the centre of the finishing cutters, it

FIG. 1.

FIG. 2.

FIG. 3.

FIG. 4.

is quite clear that the roughing operation has been performed on a given casting before the finishing operation commences, hence the finishing cutter is relieved of any influence on the part of the roughing operation and due to the slight cut taken by the finishing cutter, any inaccuracy resulting from either dull roughing cutters or in equality of castings is picked up by the finishing cutter, insuring accuracy of both finish and dimensions. Correspondingly, by the division of the work, the number of grindings of cutters is reduced. Many instances are found wherein a high degree of finish is not required, but by taking the finishing and the correspondingly faster feeds, increased production is obtained.

The principle of roughing and finishing cuts permits of operating at much higher cutting speeds and table feeds than is practical by any other process of surfacing operations. All bearings, except the spindle bearings, are oiled by cascade method of lubrication, which is pumped from a reservoir in the outer upright to the box on the top of the machine from which point it is distributed.

For illustration purpose we show various photographs of work performed. Fig. 3 depicts the roughing operation on the base of a cylinder block, the dimensions of which are shown at A in Fig. 4. From the roughing operation depicted the finishing operation can be readily understood. On this work a feed of 20 inches per minute on the maximum radius of the work was used.

Fig. 5 depicts the method of jigging casting shown at B, Fig. 4. It will be noted that this jig is of the open front type, this permitting quick loading and unloading from a roller conveyor. The time for jigging the piece shown at Fig. 5 is less than one minute. These castings have been machined in two minutes, but the usual practice runs from 2½ to 3 minutes each, depending upon the requirements and supply.

Some of the features claimed for these machines are ruggedness in all operating parts, and an excessive amount of weight in view of the fact that the parts themselves are quite incapable of absorbing any of the vibration set up by all the cutting actions, hence the machine is designed to absorb such vibration. The character of work usually presented to these machines does not require a great range of adjustment, hence with the standard model this is taken up, first, by the adjustment in the spindle heads, and second by variation in the height of the jigs themselves.

All gears are enclosed and run in oil and all essential gears are hardened. Provision is made for stopping the table for setting the cutters by a conveniently placed lever. The bearings are all sealed to prevent the escape of lubricating oil.

The Bogey of Cheap Tools

CARE should be taken lest the talk of cheaper machine tools goes farther than the actual conditions of the case will permit developments in this direction to measure up to what the buyers expect.

There are greater considerations than the bringing down of the prices of machine tools.

There have been cases where buyers have purchased cheap machine tools. They have gone on the assumption that a lathe is a lathe and a miller is a miller. At the start they saved money on the purchase, but that was the only place where there was any saving.

A buyer in the average market gets what he pays for. If he clamors for a cheap outfit, he can get his wants attended to. And when he has got this outfit housed in his premises he has exactly what he paid for—a cheap outfit.

There are greater considerations now than that there should be a slash in the price of machine tools, and the chiefest of these is that the last word in quality and stamina shall be built into the equipment that is going to be used in the industrial areas of Canada.

It would be much better for the buyer of machine tools to pay the price that will allow the maker of them to put in them the best work, brains, steel and iron that can be secured. And having paid that price he will be within his rights in insisting that when he buys he shall get the last word in shop equipment.

There is room for improvement in the quality of the work turned out in many Canadian plants. Men who have been abroad and seen Canadian products in competition with those of other lands have recognized that in some cases there was need for greater exactitude in machine shop practice.

There are makers of machine tools in Canada who have never received enough for their product to allow them to go ahead and develop along proper lines. There has been, in some cases, not enough margin on the sale to permit of experimental and engineering expenditures.

It will pay handsomely to invest a sum for mechanical equipment that will include possibilities for betterment and expansion to the maker of those tools.

Prices cut to the bone mean production at a figure rather than at a standard. A machine tool is not like a pound of prunes or a bag of sugar. Its sale does not and should not depend on the shading of the price to the last fraction.

Don't clamor for cheap tools. Much rather pay the price and insist on the quality being as high as the price.

Adequate Boiler Inspection

IN an article published in the Toronto Star Weekly the Hon. W. R. Rollo has something to say on the subject of making labor safe. In connection with this, he states, there is a demand for the inspection of every boiler in the province, in addition to the insurance inspection. Mr. Rollo intimates that this demand among others will probably be met.

While we are entirely of the opinion that every boiler should be inspected, we can see no reason why a boiler owner who wishes to carry insurance should be penalized by two inspections. If he carries no insurance, then the Government should undertake the inspection in the interest of the public and at the owner's expense. Where the owner carries insurance, an inspection is made by the insurance company's inspector, who is generally, at least, as capable as the Government inspector. Getting a boiler ready for inspection is a matter entailing time and expense, and whereas an insurance company usually make their inspection fit the owner's convenience, this will hardly enter the Government official's mind. In many cases the insurance company make their inspection at a time when the factory is closed down, and the boiler opened up for cleaning in the ordinary way.

The Province of Quebec makes every insurance inspector carry a Government certificate of competency as a boiler inspector, and holds regular examinations for candidates for these positions. Having given this certificate, the inspector has all the status of a Government official as far as his reports and inspections go. Most large and many small concerns carry insurance for the protection it gives them. To compel them to submit to two inspections would be inflicting an unnecessary hardship.

The Business Outlook

THE average man in any line of business is always on the lookout for indications of how trade is moving. This is true now in the machine tool trade in Canada and United States.

Here is a report from a large American firm that is worth noting:—

"With the election over, the general tone of business in the last week or ten days has been better than at any time in the last three months. Collections, of course, are still very bad, but incoming inquiries and actual orders from all over the country indicate that the American people have every confidence in the next administration."

And in the Canadian field? Here's the opinion of one manager who handles a lot of business in the machine tool and equipment field:—

"We are doing less business now than last month, but we are not complaining. I believe we are right in the midst of the period of price adjustment, about which we have heard so much since the end of the war. When I see a plant laying off men I might feel very much discouraged were it not for the fact that at these same premises they are building large extensions for next year's trade."

Just Taking a Chance On That Extra Trip

THE month of November is not very far advanced before we hear of the loss of a Great Lakes freighter. Fortunately, in this first case, it was unaccompanied by loss of life, although the crew went through great hardships before they were rescued. In the same storm several vessels had narrow escapes, and one barge foundered, the crew being rescued.

As the end of the season of lake navigation draws near every voyage undertaken is a gamble with the god of storms. The lake freighter, evolved after many years' experience as the ideal vessel for the transportation of bulk cargo, has been so evolved without any thought being given to her seagoing qualities.

Frankly, she is expected to keep out of the way of bad weather, being utterly unfitted to contend with it. Yet every season a certain number of these vessels are lost, too often with all hands, or a large portion of the crew.

How does this happen? Is it that the captains of these vessels, knowing fairly well what weather to expect, and well aware of the capabilities of their craft, are so imbued with zeal for the owners that they start voyages in which every element is against them, in the hope of winning through?

Or is it the owner that drives them out, anxious to get the last cent that can be made from his property?

In some cases the captain may be the owner, or part owner of the vessel, but in that case he would not be inclined to take risks. The Great Lakes are well equipped with weather observation stations, and meteorological science has reached a point where the observed conditions, compared with similar conditions over a number of years, show the probabilities for at least twenty-four hours ahead with reasonable accuracy. Harbors are fairly frequent, and, for the most part, well buoyed and well lighted. Where then is the weakness? The weakness, undoubtedly, lies in the vessels themselves.

Pitted against the terrific storms that blow across the inland seas the structure collapses. The heart of the fabric, the power plant, is not capable of holding the body up to face the seas in the most efficient manner. The mass of steel, hundreds of feet in length, becomes, instead of a ship, a mere hollow girder floating on the waves. It is either driven ashore, where it is held as in a vice while it is battered to pieces by nature's hammer, the waves, or before ever it reaches shore the hammer has done its work. Whichever way it happens, the job is very completely finished, and, too often, a toll of human life is taken.

Is there a remedy? The only one that would be of any use is one which no government would dare to take. That would be to set an arbitrary date for the close of navigation, and is out of the range of practical ideas. So long as there are men willing to take the risk, so long will we open our morning papers to read of another wreck on the Great Lakes.

The Star Weekly in its financial section says:—"According to Iron Age, the present average price of eight leading iron and steel products is $7.75 a ton, whereas a week ago the average was $80.10." Now, then, who is going to rise to say that steel prices have not been cut, slashed, pruned, trimmed, skimmed, thinned, decreased, flattened out, deflated, reduced, battered down, and all else?

Pay Promptly If You Can

FINANCING is not an easy matter just now. It is a strange situation for a firm to find that it can secure plenty of business, but cannot finance them. There are in the steel and metal industries of Canada where that is the state to-day.

Collections are slower also. Firms that do not need to do so, in many cases, are taking advantage of every means of long distance financing known to them. They issue notes and keep postponing payment as long as possible.

The serious thing is that when any number of firms start this sort of business it is not long before we find the whole business community financing on long terms instead of prompt acceptances.

It is one sure and certain way to start a vicious circle that is extremely difficult to break or wind up at a desirable time or point.

It is necessary that every leniency should be extended to worthy institutions to-day, and it is not desirable that any of them be put to the wall.

On the other hand, it is equally necessary that, under the guise of this treatment, no financially able firm shall grab the opportunity of joining the list of paper and note financiers when they are able to pay their way.

What the Business Papers Say

GET STARTED ON THE RIGHT ROAD

Mechanical World, Manchester.—We know full well the difficulties manufacturers are laboring under, and there is no quick road to the deflation of prices. At the same time a start must be made, and it is not putting it too high to say that manufacturers as a body can more easily afford to bear some initial losses due to the effect of a fall in prices on existing stocks. Behind them, of course, often come the importers, who stand to be hit most. Good profits, however, have been made in the past, and if a long period of serious unemployment is to be avoided, heads had better be put together to find a way out.

THE INFLUENCE OF WAR ON MACHINERY

Iron Trade Review.—There can be no question that designers of machinery are profiting from the experiences of the war. Many specially designed tools created several years ago under stress are now being redesigned and improved. The most noticeable feature of this remodeling process is the tendency to adapt old types to semiantomatic operation. This is accomplished on boring mills, milling machines and similar tools by providing rotating tables with from four to eight chucks, so that the work may pass from one set of cutters to another for the various operations. For duplicate work, these machines greatly increase the output per man and in some instances it is possible for one operator to handle more than one machine.

OBSOLETE TOOLS ARE A NUISANCE

Machinery (New York).—Light cuts and slow speeds greatly decrease production, and the inaccurate work from many obsolete tools increases the time required for assembling machined parts. These old machines are also a source of discouragement to the men who must use them—a factor not to be overlooked. It is well known that locomotives are kept in repair shops longer than is necessary owing to the use of obsolete tools, and a careful study of conditions in representative repair shops shows that the loss from this source is even greater than is generally realized.

HIGHER WAGES NOW ARE DANGEROUS

Canadian Engineer:—Contractors and supply dealers are of the opinion that a reduction in wages, rather than an increase, can be expected. They say that living costs are slowly but surely reaching a lower level, and that propaganda for wage increases in the face of existing conditions in the construction industries is having a serious effect on general business. A vast amount of construction throughout Canada has been postponed in the expectation that prices of materials and labor would not remain at war-time levels very much longer, and propaganda for further increases is causing the total abandonment of many of these projects.

Motors and Their Correct Application

The Characteristics of Motors in Terms of Their Speed and Torque in Relation to Different Kinds of Loads is Discussed by the Author

PAUL AND LINCOLN

AN interesting paper bearing on the above title was read before the Toronto Electric Club by Mr. Paul Lincoln of the Lincoln Electric Co., recently.

Mr. Lincoln prefaced his remarks by some reference to the historical side of power development, and quoted largely from a book called "The New Epoch", by George S. Morison. Mr. Lincoln especially drew attention to a quotation occurring in that book, as follows: "Wherever needed, we can now produce practically unlimited power." Mr. Lincoln used this quotation as a text for his talk, which here follows:

The particular point that I wish to make is that the significant thing that is bringing about Morison's "New Epoch" is not entirely the "manufacture" of power, but largely the ability to distribute this power to "wherever needed," and that latter ability is the distinct contribution of the electrical profession. It is the problem of distribution that has been solved most completely by the alternating current polyphase system. The ease, efficiency and safety with which alternating currents can be changed from one voltage to another by means of the static transformer has given that system so great an advantage that it has no competitors, in so far as the distribution problems are concerned. In point of adaptability to driving the great multiplicity of loads that motors are applied to, the alternating current motor lacks some of the flexibility of the older direct current motor.

Before the advent of the alternating current polyphase motor the direct current motor had a considerable vogue, and in some applications its greatest flexibility has caused its retention in service in spite of the increasing prevalence of the alternating current polyphase distributing systems.

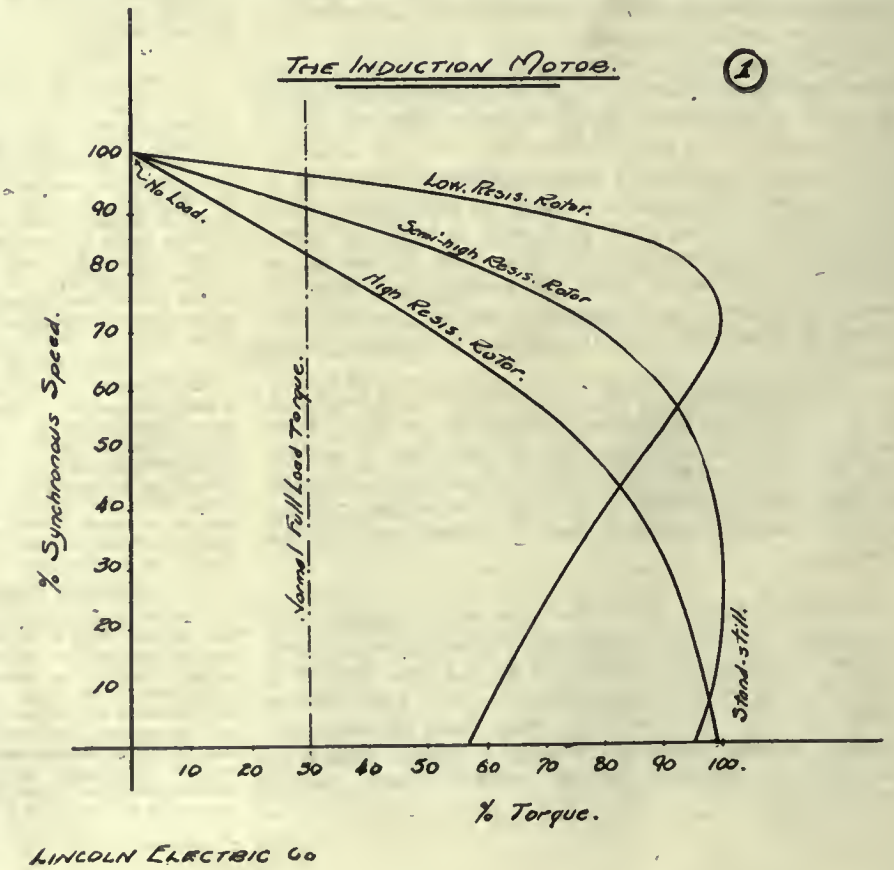
The contest that has been waged between A. C. and D. C. during the last 25 years has gone in favor of A. C. not because the A. C. motor is more rugged, but solely due to the superiority of the A. C. for distribution. It is the ability to put power "wherever needed," in the words of Morison, that has won the battle for the alternating current. The problem of applying motors to the diversified work that they have to do is in general more easily solved by the D. C. motor than the A. C. However, by careful analysis of the work the motor has to do as well as a complete knowledge of the characteristics of the A. C. polyphase motor; the A. C. motor has been successfully applied to every class of work that motors are called on to do.

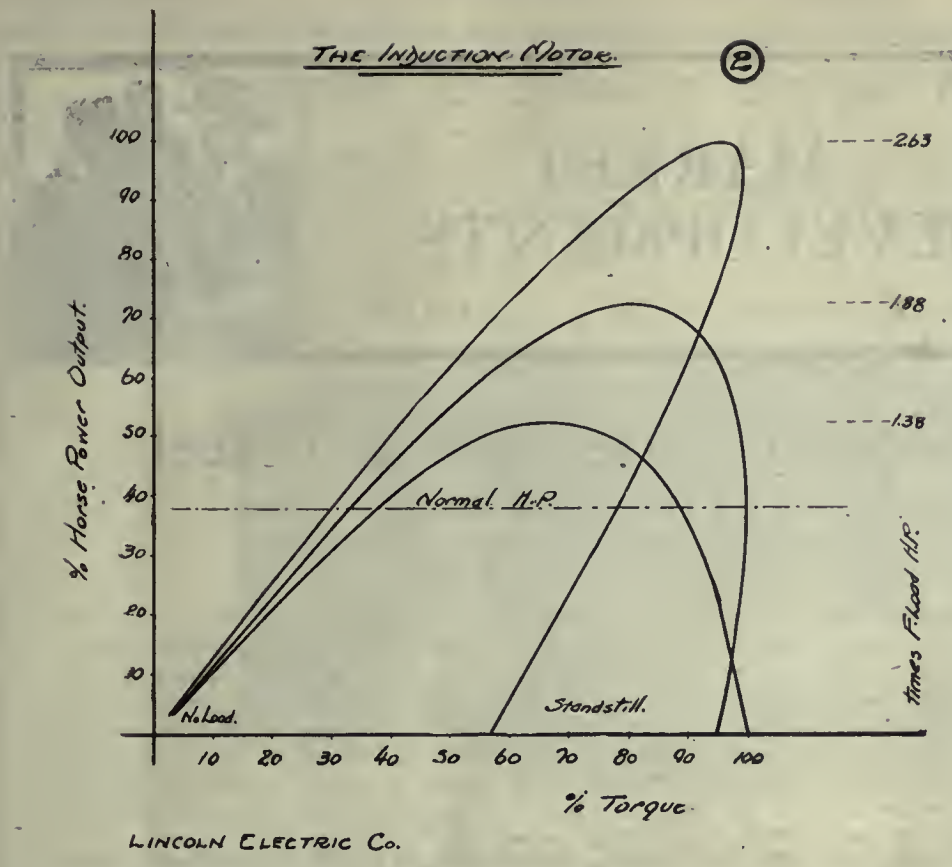
The ease of distribution of A. C. polyphase currents is bringing about a complete revolution in the method of operating our modern factories. Time was when the water wheel or the steam engine was a source of power, that it was customary to equip a factory with a single prime mover, and then distribute this power throughout the plant by means of shafts and belts. During this period, shafting and belting took so firm a hold that it is exceedingly difficult now to think of a factory installation without thinking of a room full of shafting and belts.

The "wherever needed" is not a single point in the factory, but the individual machines that are operated therein. To carry Morison's dream to its logical conclusion, we must power equip, not a factory, but the individual machines in that factory. The electric motor is successfully taking the place of the steam engine in factory drive, but its job is only half done when we substitute a motor for the former engine and leave the belts and shafting. The job is completely done only when the idea of motor drive is carried to the ultimate of the "wherever needed" that Mr. Morison emphasizes.

Now the problem of applying motors to the ultimate machine wherein power is used involves first an analysis of the power characteristics of these machines, and second a complete knowledge of the nature of the motor to be applied and of the modifications of design that are possible thereon. The most important characteristic of a load, at least, when considered in connection with a driving motor, is its speed torque character. The most usual demand in this respect is that the speed shall be independent of the torque or practically so. When factories were driven by a single prime mover, either water or steam, this constant speed characteristic was the one demanded and when electric motors began to supplant other prime movers, it was natural that this constant speed characteristic should be the one most in demand. Both the A. C. and the D. C. motor were able to meet this requirement easily.

A second requirement often demanded in a load is the ability to adjust the motor speed to a new value and when so adjusted, still to have its speed independent of its load. This is a require-





LINCOLN ELECTRIC CO.

ment that can be met by the D. C. motor with relative ease, but is impossible of fulfillment by the A. C. motor. It is this requirement that has done more to keep the D. C. motor in service in competition with the A. C. than any other one requirement. Machine tools is the particular duty where this requirement is most in demand. The absence of this ability to give constant speed characteristics over an adjustable range of speed is the A. C. motor's weakest point. Methods of securing this ability with the A. C. motor undoubtedly will be forthcoming in time; but whether they can be secured at a reasonable cost and, what is most important, without a sacrifice of the ruggedness and reliability of the induction motor, is a still unanswered question.

A third load requirement frequently called for is one where torque forms the important element rather than speed. Such loads are typified by the elevator and the hoist. In applying motors to such loads, constancy of speed with carying torques, is of no consequence. The type of motor to meet such requirements successfully is quite different from the first two where constancy of speed is essential. The operation of railway cars and trains is another example of load where torque plays a much more important part than speed.

The above three classes of load are only a part of those that are met in practice. Loads may be classified not only in regard to their speed-torque characteristics, but also in regard to their power-time character or the "intermittancy" of the load. Consider for instance the power-time character of a punch-press or a forging press. During a large part of the time of operating a machine of this kind, the only duty of the motor is simply to turn the machine over idle. At intervals, more or of the work, power is expended on the work for a short time, after which there is another period of comparative rest. In a punch-press for instance, the time during which power is actually being expended in shearing the metal is exceedingly small, but during that small instant the rate at which power is used may be exceedingly large. In such applications, it is customary to use a fly-wheel which stores sufficient energy to do the active work of shearing the metal and then rely on the motor to restore the energy to the fly-wheel during the comparative long interval between successive strokes. The characteristics of a motor for this work obviously differ materially from that to operate a lathe for instance, where the work is done at a uniform rate. Or take the case of an elevator motor; the rate of doing work here varies greatly between the starting period, when it is necessary to accelerate the car and its load, and the running period, when it is necessary simply to lift the load. Also, the load on the motor varies greatly depending on whether the car with its maximum load is being lifted or lowered. The motor obviously must be of different size and character to care for the maximum conditions that are imposed upon it, and the problem of the proper rating to give the motor that does the work properly is not an easy or a simple one.

As indicated in the foregoing, the problem of applying a motor to its load is first—a thorough understanding of the nature of the work to be done, and second—a thorough understanding of motor characteristics and the modifica-

MARKET DEVELOPMENTS

A Quiet Season in Tools, Iron and Steel

Trading is in Small Quantity, But There is Generally a Dull Season at This Time of Year—Steel and Iron Prices Stay Up Much Longer Than Figures in the Non-Ferrous Lists.

BUSINESS is quiet in the machine tool, iron and steel market. But in saying that one should take into consideration that at any time this is a quiet season in these lines. Little purchasing is ever done in the steel market during the last half of November and December, and it is hard to say how much this accounts for the present state. Prices are holding firm, though, and if there is any tendency in the U. S. steel market to let prices sag seriously it is not being reflected here. In some lines the demand is good and deliveries not in keeping with the immediate requirements.

It is doubtful if a decrease in prices would bring much new business into the market just now. As a rule, machine tools are not sold because the price is attractive, but because they are wanted to do a certain work, buyers preferring to pay the high price and insist on the quality being equally high. Some makers have announced reductions, but the movement has not become general. It had been expected that the meeting of tool builders in New York would be followed by something approaching a general announcement regarding policy and prices for the ensuring year, but so far there has been nothing forthcoming apart from the announcement of the president that costs were still very high, and would hardly permit of reductions. Tool builders in Canada are in the same position, and it is very doubtful if they can make reductions that would assist sales.

Buying in the small tool division is small, and the territory is being combed for business more thoroughly than any time since the beginning of the war.

The scrap metal market is becoming known for the business it is not doing, rather than for any volume of trading that is taking place. Prices have been cut to the bone, but the market remains the same, listless and inactive. The big buyers, even at low levels, are not in the market.

CLOSE OF NAVIGATION IS FELT IN BUSINESS AT MONTREAL NOW

Special to CANADIAN MACHINERY.

MONTREAL, Nov. 18.—The near approach of the close of navigation is having its effect on trade in this district. It is expected that for a short period at least the railroads in this locality will be additionally active in hauling freight to the seaport of St. John, N.B., which port will carry on the bulk of the winter trade to and from overseas. Reports seem to indicate that business is gradually developing a quieter trend, particularly in manufacturing lines. Business in machine tools has shown a slight falling off, especially in orders on new equipment. Supply demand is steady. Some dealers report fair business while others infer that turnover is light. The aggregate business is possibly lighter than for some time, but dealers are not discouraged as they realize the present dullness is quite seasonable, owing to the nearness of the year's close.

Lower Levels Anticipated

There is a marked tendency in all quarters to liquidate supplies on hand before further placement of orders. When buying is necessary a conservative policy seems to rule, and in consequence the market in every direction has taken on a dullness that promises to continue for the remainder of the year, with possibly a slight fluctuation both in price and volume of business. The consumption of materials for industrial enterprise is gradually lessening, and with mills and furnaces endeavoring to maintain operations, rather than reduce their staffs, the available supply of many commodities is in the ascendency, and with very few exceptions the cry of "shortage of materials" is seldom heard. Premium business is seldom reported now. Dealers are not anxious to acquire large warehouse stocks, but are trying to keep sufficient on hand to meet their customers' needs as they arise. While the factor of price is, no doubt, an influence in keeping the consumer from buying ahead, the chief difficulty is the uncertainty that features the industrial situation at the present time. Should weakness develop to the point of heavy price cutting the element of labor would necessarily have to be taken into serious consideration, as existing conditions in this field prohibit profitable operations unless relative reductions are effected in the cost of production. Steel quotations are generally firm but the factor of price is of minor importance in face of the poor demand. Price revision on the market basis doubtless is pending, but dealers are reluctant to take definite steps in this direction until the turn of the year. It is possible that actual orders would bring out better figures than those quoted, but with trade on the ebb, dealers are satisfied to let the nominal prices stand.

Additional Weakness Develops

Absence of activity in the old material market has added to the dullness that has been more or less marked in this field for some time. Despite the declining trend of prices on almost every line of scrap, the lack of interest on the part of consumers keeps the situation in a state of listlessness. Conditions are not conducive to heavy buying of scrap and

Warner & Swasey Screw Machines

For large output and close limits—If you are figuring on screw machine work you can depend on W. & S. machines being right for the job.

We can supply you from stock immediately.

users are content to acquire scrap sufficient to meet their present needs, leaving the future to look after itself. There seems little hope that business will show improvement during the next two months, and the outlook for the early period of 1921 is shrouded in uncertainty. Further reductions have been made by dealers here and quotations reflect the inactivity of the general situation. The range of decline in non-ferrous lines is from ¼ cent on heavy lead to 2½ cents on heavy copper. Crucible copper is now quoted at 13½ cents and light at 10½ cents per lb. Almost the entire list has been affected. Iron and steel lines are again weaker, the declines ranging from $1 a ton on machine shop turnings to $5 per ton on boiler plate and wrought iron axles. Malleable scrap at $23 is quite firm. Volume of scrap movement is exceptionally light.

BUSINESS QUIET IN SOME LINES

But Even In Normal Times There Is Generally a Lull at This Season of the Year

TORONTO.—The market is quiet now in several departments. It is very easy to go wrong in estimating how much of this is seasonable and how much is not. Many lines of business became accustomed to going through war years with no off-seasons, so that they have come to expect the same thing is going to hold good in the markets for all time to come. There are lines, several of them in fact, in the iron, steel and machine tool fields that have always been more or less flat at this time of the year, and this season, being about the first when trade is on the way back to more normal conditions, is apt to be looked upon as exceptional because it does not measure up to war years or to the unexpected conditions that followed the war.

Trade in machine tools is quiet. One may advance many explanations for this, but it does not alter the fact. Many firms have some very interesting quotations out now, and they expect to convert some of these into real business. The matter of price is discussed openly, and there is a very marked difference of opinion as to whether a reduction would assist in the sale of any more machines under present conditions. The experience of several dealers can be summed up in the opinion of one who stated, "Nearly every sale that we are making now is made because a firm realizes the need for a new tool in some department. They see where there can be a saving made by the introduction of the new equipment."

"I am open to admit that our business is not brisk now," stated one firm to Machinery this week, "but what of it? One has only to look around a little to see ahead and anticipate what is coming. I can take you to a plant where a number of men have been laid off. On the face of the thing that is not very hopeful, is it? But go on around to the other side of the same premises, and you will see that they are busy putting up a great extension to their existing place. Does that really look as though they see the bottom dropping out of things around here? No, it means that they are getting ready for a lot of business they hope to do next year."

Selling Small Tools

Firms handling Canadian high speed are working on the new list, announced in last week's issue of Machinery. This price schedule puts them on an equal footing with the British firms, which have heretofore been able to sell under the Canadian quotations. Business is not brisk, although there are a number of small orders to handle. One thing is certain, and that is that the shops are being combed for business now as they have not been for some time, and the dealers are putting on more steam than usual. In fact, there is a revival in selling in all lines of machine tools, including the small tools.

There may be a tendency on the part of some dealers to put certain parts of their stock up for clearance at this time of the year. Many of them end their fiscal year in the near future, and in order to make the year's business as good as possible, an extra selling cam-

paign may be inaugurated to move as much stuff as possible, even in this dull season.

Referring to the recent reduction in the price of high speed, one of the dealers remarked, "In this case we simply have to take our loss and go ahead. When the prices of goods in stock go up we stand to gain, and when they go down we have to take our losses. It can't be a case of 'we win' all the time."

The Steel Market

There has been some improvement in deliveries during the week, and some shipments are coming to light that have been on the books of the U. S. mills for almost a year.

Prices are remaining firm, and there is nothing in the local markets to reflect a dropping away from the selling schedules that have been in use for some time. It would be nothing out of the ordinary were business to fall off a little at this season, as it has been the experience of steel merchants in normal times that from now on to the first of the year business has never been brisk. Allowance should be made for this in considering the volume of trade that is passing now. There is a good demand for certain lines. The larger sizes of tubes seem to be fairly well supplied for this season. Many plants have decided to go ahead with existing equipment for the season as they cannot close off now. This affects the larger sized tubes, but there is still a demand for the 2-inch variety for the smaller plants, and it may be some time before the demand for these is satisfied.

Scrap Still Dull

"Nothing better in sight," was the comment in the scrap metal market this week. Trade is very weak, and the tonnage that is moving is limited to contract commitments. Dealers find that buyers are not coming into the market even at lowered prices.

In this connection it seems necessary to again call attention to the fact that the prices quoted on another page of this paper are Dealers' Buying Prices. That is, Toronto dealers will pay those prices for material. We have had several requests wanting to know where scrap material could be secured at the prices mentioned. It is almost impossible to get together a fair resale list, as selling is done subject to a good many conditions. If firms want to buy direct from those having scrap metal to sell, we would advise their use of the advertising columns of this paper, stating just what they wanted to secure, and they would probably find out then how much they could get.

POINTS IN WEEK'S MARKETING NOTES

Cancellations are coming in, although they are not at as great a rate as formerly.

Lead is now 50% above the 1913 price; zinc 20% above; copper 6% below; tin 15% below; pig iron is 172% above, and finished steel products in general 110% above.

Independent steel mills are maintaining prices in nearly every case, believing that reduction would not bring them any new business.

Pittsburgh reports state that independent steel mills are freeing bars, shapes and plates at 3c, and that 6c is a common quotation for black sheets 28 gauge. The National Machine Tool Builders met in New York, and although the quotation of prices was discussed at some length the general feeling seemed to be that when the costs of production were so high at the present time there was small chance for reduction to be made in price.

Firms that are selling lines that are used largely by farmers report business as being very active and sales are very satisfactory.

Steel merchants in this district are doing very fair business, although at this season of the year, even in normal times, there is always a falling off in the volume of trading.

The new price list which is being used by the Canadian high speed tool trades, now meets the price that has been used by the British firms for some time. Heretofore the old country high speed has been able to undersell the Canadian production.

MACHINE TOOL BUILDERS HAVE NOTHING ON PRICE REDUCTION

Special to CANADIAN MACHINERY.

NEW YORK, Nov. 18.—The National Machine Tool Builders' Association held in New York last week its nineteenth annual convention. Quite naturally the present business situation was the principal topic of discussion both in and out of the convention hall. President Albert E. Newton, in his opening address, pointed out the problem which the average machine-tool manufacturer faces, namely, the expectation on the part of the buyer that prices will go lower and the fact that costs of manufacturing machine tools are little if any lower. Mr. Newton expressed the conviction that price reductions at this time would avail nothing in stimulating renewed buying activity. This sentiment was echoed generally by the manufacturers attending the meeting, and the impression was gained that many, if not all of them, will cling to their present price schedules for the present, at least.

Cancellations were also discussed. The fact that some machine-tool manufacturers have had cancellations aggregating several hundred thousands of dollars made this subject of unusual importance. The machine-tool builders were at a loss to suggest any way by which cancellations may be minimized in a time like the present, except by a process of educating the buyer that he must feel a larger share of responsibility in placing an order. "A reawakening of the business conscience is needed," according to one speaker.

While there was no concealment of the fact that machine tool business in the United States has at present hit what is possibly the worst slump in its history, there was no pronounced feeling of gloom at the convention. Rather, the machine-tool manufacturers look for a resumption of business activity within a few months, by spring at the latest, and possibly sooner, and most of them are understood to be financially able to weather the storm.

In the local tool market there is very little change. Some sellers seem to detect a slightly better tone, as evidenced by a few more inquiries, but it is certain that if there is any improvement it is not general. Some tool builders are doing little or nothing here. There are expectations of railroad buying, but as before reported these prospects are somewhat nebulous as yet.

The General Electric Co. has issued a new list of about 20 tools, including 10 lathes, for a new plant which it is reported may be built in or near Newark, N. J. As the General Electric Co. has other pending inquiries, on which no action has been taken, the above-mentioned list has not occasioned as much interest as might otherwise be expected.

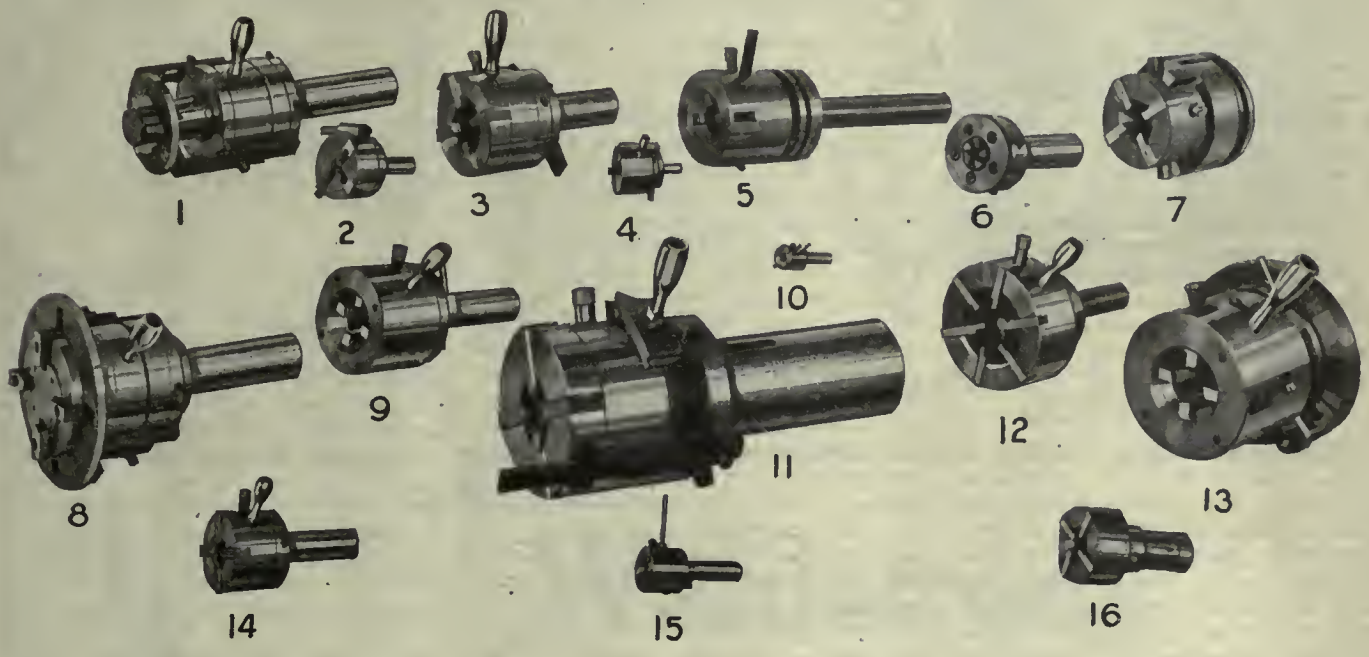
Would Sell Its Plant—The plant constructed by the Brantford Industrial Realty Co. for the A. C. Spark Plug Company in the Holmedale district of Brantford, has been placed on the market as a result of uncertain conditions in the automobile industry. An officer of the realty company stated there was a possibility that the Spark Plug Company would start operating next spring, but any offers for the purchase of the plant will be entertained.

Increased Output.—Alberta's output of coal for 1920 has increased 30% in excess of last year's. A total output of over 6,500,000 tons is expected by the end of the year.

55
466

GET THEIR NUMBER

Numbers 1 to 16 represent one of the Geometric Self-opening and Adjustable Screw Cutting Die Heads, Solid Adjustable Die Heads and Adjustable Collapsing Taps.



No. 1—Class N-L Pipe Tap. Made in sizes from ⅛" to 10" inclusive. Represents tapped diameters of 1-1/16" to 13-1/2" straight threads, and 3/4" to 12" standard pipe threads.

No. 2—A Geometric Brown & Sharpe Taper Turning Tool.

No. 3—Style C Die Head, Lever Trip Type. Recommended for cutting threads of short length.

No. 4—Two-Chaser Class U Tap, for tapping fine pitch threads, ranging from 1/2" to 1-5/16" diameters.

No. 5—Style D-D Die Head for Cleveland Automatic. Floating and tripping adjustment features make this a very desirable Die Head for these machines.

No. 6—Adjustable Hollow Milling Tool. The cutters are readily removed for sharpening. Micrometer adjustment makes quick and easy aettings.

No. 7—Rotary Die Head. Recommended for live spindle use.

No. 8—Class P Tap, Plate Trip Type. Used wherever tripping plate can come in contact with the work.

No. 9—Style D Die Head. For general use where thread is not too short. Made in sizes from 5/16" to 4-1/2" inclusive. Represents threaded diameters of 3/32" to 4-1/2".

No. 10—A 1/8" Style D Die Head, the smallest size. Cuts down to 1/16" diameter thread.

No. 11—Taper Threading Die Head, with inside trip and roughing and finishing attachment. Recommended for coarse pitch taper threads.

No. 12—Style C Die Head, Inside Trip Type. For cutting short threads where the length of thread is best controlled by an adjustable internal gauge or stop.

No. 13—Style D-D Die Head, with roughing and finishing attachment. Flanged for Warner & Swasey Turret Machine.

No. 14—Style C Die Head, Pull Off Type. For cutting threads on light work.

No. 15—Style C Die Head for Brown & Sharpe Automatics.

No. 16—Solid Adjustable Die Head with floating shank, for Gridley Automatic.

These Die Heads and Taps are adapted for use on the turrets of practically all makes of hand and automatic screw machines and turret lathes.

By using extra sets of Thread Chasers, each tool can be used for a range of diameters; the larger the size of tool, the greater the range.

Make screw thread cutting the most satisfactory operation in your Shop. Let a GEOMETRIC show you how.

STEEL AND IRON STAY UP MUCH LONGER THAN MANY OTHER LINES

Special to CANADIAN MACHINERY.

PITTSBURGH, November 18.—Open market demand for steel products continues extremely light. There is a fair, though slowly dwindling, demand for steel products against contracts. Some cancellations are still coming in, though not at as great a rate as formerly, and there are some postponements. Thus far at least the Steel Corporation has not been affected, but all the independents have had to restrict production more or less, even those that had order books apparently well filled, and this decline in independent steel production promises to continue until there is a fresh buying movement to replenish order books. The prospect of such a change is more indistinct than it appeared two or three weeks ago, for the general business situation is worse than it seemed to be recently.

Iron and Steel Exceptional

Indeed, a proper appraisal of the prospects requires the fact to be emphasized that the iron and steel industry is exceptional among industries as to its present position. No matter what the prospects may be, the iron and steel producers are making money now, and they have been making a great deal of money up to date. Practically all other industries have been in bad shape for weeks or months. The automobile, tire, textile and various other industries have come almost to a standstill, and with large stocks of manufactured goods which they find it difficult to liquidate. In the non-ferrous metals there have been very heavy losses. Lead is 50 per cent. over its average price in 1913, zinc is 20 per cent. above, copper is 6 per cent. below and tin is 15 per cent. below. Iron and steel prices make a sharp contrast with these metal prices, for pig iron, even with the recent declines, is 172 per cent. higher. The finished steel excess over 1913 would be greater still were not the Steel Corporation prices given some weight in determining the general average at present.

So much for price comparisons. As to demand, it is true there is very little demand for pig iron and steel products in the open market, but the production is being taken on old contracts, and the production is off only a few per cent., hardly much more than 10 per cent. from the high point, and it is fully one-fourth, perhaps one-third, greater than production in 1913. As the production is being taken, and as both producers and consumers are endeavoring to decrease stocks rather than increase them, the rate of consumption is evidently large, whereas for many commodities there is almost no demand at all.

The natural deduction to be made from this remarkable divergence is that the iron and steel industry is simply running on its momentum. It cannot expect to continue prosperous when other industries are not; but rather, when it will certainly take considerable time for business in general to revive from the very poor situation now existing, one should conclude that in iron and steel "the worst is yet to come."

Steel Production

The monthly report of the American Iron and Steel Institute indicates that production of steel ingots in the United States during October was at an average rate of about 42,950,000 gross tons a year. That is one-half of one per cent. heavier rate than the rate in September or August, the highest rate since last March, and the highest rate since December, 1918, barring February and March of this year. Yet during October it was well known that many producers were decreasing output. It seems strange that the total should have increased at all. The explanation is that the Steel Corporation, being well fitted with business, endeavors to run full, and experienced somewhat better operating conditions in October, while as to the independents, their decreases were progressive during the month and their average for the month was well ahead of their present rate of output. The November and December figures of production will probably show sharp decreases from the October rate.

Prices Slow to Yield

If any independent steel producer is selling any description of steel at the Steel Corporation (Industrial Board) price the case is altogether exceptional. As a matter of fact the independent prices are very slow indeed to yield to what is considered the inevitable, a decline in the independent market to the Steel Corporation level. As an augury for the future that can hardly be considered as altogether favorable. The mills have no agreement to maintain prices, nor are they receiving anything like enough business to support the market. It seems clear that the mills that are maintaining prices are doing so because there is so little temptation for them to reduce prices, no business of consequence being offered. There is a lack of competition not because mills refuse to compete but because the subject matter for competition is lacking.

On bars, shapes and plates the common quotation of independents is 3.00c. No doubt there is shading in some cases but there does not appear to be much. Sheets, however, show a constantly declining tendency, 6.00c being now done easily on No. 28 black. For several weeks the black sheet market has declined at an average rate of about a quarter cent a pound per week. Blue annealed in the heavier gauges could probably be had at about 4.00c, though for 14 to 16 gauge the price might be nearer 5.00c basis. Galvanized are about 1.50c above black.

Easily the strongest item in the finished steel list is tubular goods. There is heavy demand for shipments on contract, customers desiring mills to make heavier shipments than they are able to make. While the independents generally have a basis price, $7 a net ton above the Steel Corporation (54 per cent. as against 57½ per cent.) some orders even now are being taken at delivery premiums ranging up to $10 a ton, or $17 altogether above the Steel Corporation price.

Pig Iron

Since last report foundry pig iron has been offered by producers at $40, valley, or $1 under the reduced price of a week ago. Bessemer and basic are steady but extremely quiet. The market now stands at $40 for foundry, $42 for Bessemer and $38.50 for basic, f.o.b. valley furnaces, these prices representing declines from the top point, reached last August, of $10 on basic and foundry and $6.50 on Bessemer. Prices have slid off very easily, with practically no resistance, but furnaces are taking a new stand. They feel that enough has been done by way of reductions that were almost voluntary in character, and assert that if consumers want still lower prices they will have to offer orders that would make it worth while to cut prices. As there is no likelihood of consumers getting in the mood in the near future to buy to any extent, no matter what the prices, the furnaces feel they might as well save some of their ammunition. Very recently it was a common guess that pig iron on this decline would find its level at not under $30 nor over $35, but it looks now as if the readjustment will prove more drastic than a decline only to $30.

Serious Car Shortage.—Another serious car shortage is said to threaten Drumheller's mines. There are only enough cars to keep seven mines working part time, and there are no more cars in sight, although the demand for coal from the rest of the prairies which are not stocked up with coal is increasing. One thousand men are idle and two thousand will be idle when the daily output of 7,000 tons will be cut off.

Annual Meeting.—One change was made in the officers of the Cockshutt Plow Company at the annual meeting, E. A. Mott being added. The directors are: Col. H. Cockshutt, George Wedlake, G. K. Wedlake, Sir Augustus Nanton, E. A. Mott, Sir Lomer Gouin, H. W. Hutchinson, James Adams, E. Perry. The reports presented were reported as very satisfactory to the shareholders.

Aikenhead's

Single Spindle Hand Tachometers

Hand Tachometers supply the need for accurate, durable and handy speed recorders for all-around use. They indicate accurately the revolutions per minute, **either right or left hand,** of shafts and spindles; furthermore by using the measuring disc, periphery or surface speeds are determined. The result (either revolutions per minute or feet per minute) is instantly shown on the dial **without watch-timing or calculating** of any sort. The slightest **variation in speed** occurring during a fraction of a minute is also shown **at a glance.** Belt slipping and consequent loss of power is, therefore, quickly detected.

Wahlstrom

Self-Centering, Automatic Drill Chucks

With a Wahlstrom, two seconds is all you need to change the operation from drilling to reaming, counterboring, or tapping—and you don't stop the spindle; simply grasp the chuck with one hand and replace the loosened tool with another.

The instant-acting jaws of the Wahlstrom close on the entire shank with a grip that becomes firmer and firmer as the resistance to the tool increases.

Made in two styles. One holds Nos. 1, 2 or 3 Morse Taper Shank Tools—with or without tang. The other is made in three sizes—15-64 to 1-2 in.; 3-8 to 3-4 in. and 17-32 to 1 in., thus holding all sizes of straight shank tools from 15-64 to 1 in. Booklet upon request.

Canada's Leading Tool Supply House

Our large stocks enable us to supply "Everything in Tools." We are prepared at all times to fill your requirements promptly—be they large or small. This, and efficient, courteous service has made Aikenhead's **Canada's Leading Tool Supply House.**

Ryerson-Conradson Machine Tools

LATHES
RADIAL DRILLS
MILLING MACHINES
PLANERS

The Ryerson-Conradson High Power Precision Selective Head Lathes are the result of long and thorough study of lathe requirements.

They have been taken out of the old time class of machine tools. They are designed and built for accurate, quantity production.

Ryerson-Conradson Lathes are superior to all modern lathes—and we can prove it. The new features will surprise you.

INDUSTRIAL NEWS

NEW SHOPS, TENDERS AND CONTRACTS PERSONAL AND TRADE NOTES

Building in Galt.—The local commission of the Hydro have decided to erect a fine modern public utilities building at the corner of Dickson and Wellington streets, Galt. They expect to proceed with the work during the coming year.

New Coking Plant.—It is reported that the United Gas and Fuel Co. intend commencing the erection of a three-million-dollar coke oven gas plant in the northeast end of the city of Hamilton.

New Library.—Plans are under way for the beginning of the new Carnegie library at Lethbridge, with the promise of $25,000 made by the Carnegie Foundation for this purpose. It will consist of a daylight basement and one storey above it.

Call for Tenders.—Plans are nearing completion and it is expected that tenders will be called for during the winter for the addition to the Ritz Carlton Hotel, Montreal. The addition will add 150 rooms, will be nine or ten storeys in height, and cost about $750,000.

May Build Hotel.—An unofficial report has spread about that tentative plans are entertained by the Canadian National Railways to erect a hotel in Quebec along the lines of the Chateau Laurier, Ottawa.

Steel Contract.—The Hydro Electric Power Commission of Ontario has awarded the Dominion Bridge Co., Ltd., the contract for five large penstocks for its Queens plant. The contract calls for early erection, as part of the plant must be in operation by September next year. Over 2,000 tons of steel are involved in the contract.

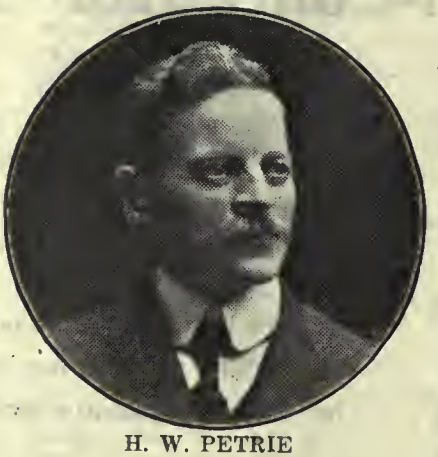
New Molding Shop.—A new molding shop is being started at Kingston, Ontario, by Messrs. Kelly and Driver. It has been stated that the ratepayers will be asked to give the company a free site on Montreal St., at a cost of $2,000, and exemption from taxes for ten years.

Large Building.—Although the actual construction work will not start till next spring, preliminary surveys are being made of the grounds along the Trent Road on which the new Albert College is to be erected at Belleville. Chapman, Oxley & Bishop are the architects, and Mr. Oxley is the engineer. It is expected that an outlay of a million dollars will be necessary.

GIFT TO ASSIST HOSPITAL WORK

H. W. Petrie Remembers the Hospital In the City Where He First Started Business

H. W. Petrie, president of the H. W. Petrie Co., Ltd., Toronto, has remembered his old city, Brantford, where he first started in business. The remembrance has taken the form of the setting aside for a term of five years of $25,000 Victory bonds, the interest to be paid half yearly to the hospital. In his letter to C. H. Waterous, president of the Brantford General Hospital, Mr.



H. W. PETRIE

Petrie pointed out that his "first business venture took place in Brantford, of which for many years I was a citizen, and, despite my removal some thirty years ago to Toronto, the interests and developments of the place have always been very dear to me. In this regard I shall deem it a privilege to do something on behalf of your splendid public institution."

C. H. Waterous, in accepting the gift, stated: "Your citizenship here is still recalled with pleasure and profit by many old friends, who take pride in the success which has so worthily crowned your business enterprise and integrity, and who deeply appreciate that in the days of your well-earned prosperity you have decided to remember in so tangible a manner the place and the people associated with your early life and commercial efforts."

The Brantford "Expositor," commenting editorially on this, remarks: "The hospital board has not received much encouragement of this kind in its labors, and the generous action of Mr. Petrie is consequently greatly appreciated by them. It is hoped also that it will prove an example to others."

DRAWN STEEL PLANT IS BUSY

Hamilton.—Speaking of the steel industry in general, S. J. Waddie, president of the Canadian Drawn Steel Company, stated that its immediate future was not likely to be affected to anything like the same degree as other lines of industry might be.

As for the company he is associated with, Mr. Waddie said there were sufficient orders on hand to insure uninterrupted operations for a long time to come. Retrenchment was something his company had had no occasion to consider so far. All employees were at work and the plant was operating at full capacity. The greater part of its production was for the domestic market.

"We could get much more work to do if we could only get the raw material," observed Mr. Waddie, "but we experience the greatest difficulty in this connection, with the result that our export market has been crippled somewhat."

Use Northern Rock.—The Silica Granite Products Company, Ltd., is a company formed under Ontario charter, having headquarters in Hamilton, Ont., president, A. R. C. Smith, secretary-treasurer, A. Caddie. The company's property is situated in the township of Henwood, New Ontario, and consists of 160 acres, whereon is a very extensive formation of granite rock. This rock, when quarried and crushed to various sizes is a base for cleansers of various kinds, such as dry and wet hand cleaners, household cleaners, etc. A medium size of the rock is found to be exceptionally good for foundry use in sand blasting of castings. The rock is used for monumental work, is similar in color and hardness to Scotch granite. There are in all, at present, twenty-one known uses for this product, which assures it an extensive market. Installation of machinery is almost completed, and the company expect to ship about December 1, 1920.

The Week's Events in Montreal Industry

Industrial incorporations for the past week include the Forged Steel Specialties Company of Montreal, $500,000, and the Canadian Piston Ring Company of Montreal, capitalized at $75,000.

Hodgson Freck, Ltd., of 369 St. James Street, Montreal, foundry, mill and metal merchants, have secured the Eastern Canadian agency for Robert Drury of Canada, Ltd., of Toronto, manufacturers of hardwoods and veneers.

At the November meeting of the Canadian Railway Club, in Montreal, a paper on "How to heat railway buildings economically" was read by R. H. Black, engineer of power plant construction of the Grand Trunk Railway Company. A large gathering of the members was present and the discussion following the reading of the paper indicated the great interest that was taken in this subject.

Malcolm Lemieux has recently purchased large interests in Motor Car Distributors, Ltd., and has been elected a director and appointed general manager of the entire concern. He has secured district agencies for all of Eastern Canada for Peerless and Chandler cars, and Beaver Hall, the new four-storey spacious building on Beaver Hall Hill, Montreal, has been acquired for offices and warerooms. Mr. Lemieux has spent his entire lifetime in the automobile business.

The Armstrong Whitworth Company of Canada are entering on a new line of activity in the shape of marketing an English make of automobile manufactured by the Armstrong Siddeley Company of Coventry, England. Every part of this car, even to the tires, is made by the Armstrong Siddeley Company. This car is of exceptionally high grade quality and is designed especially for the convenience of the owner-driver, simplicity of operation being an important feature. In design it is entirely original, and embodies experience gained during the past four years. This is particularly true of the six-cylinder engine, which is that known as the Deasy aircraft engine. These cars will sell at $8,500 and $11,000.

MACHINE TOOLS CANNOT COME BACK TO LOW PRE-WAR LEVELS

"HOW about prices? Well, for the life of me I can't see where there is any great cut coming, and I don't think it is well that we should do anything to lead the buyers to believe that such will be the case for the present at least."

That is the way the manager of a firm of machine tool dealers sized up the situation for Canadian Machinery.

"For a long time," he continued, "there have been makers of machine tools that have never made much money. They have never had enough margin to allow them to go ahead and develop as they should develop. They have never been able to afford a research department or do the experimental work they should. The machinist, too, for years, was a low paid man when compared to the outside trades, in many of which there was not nearly the skill required that the machinist needs in his work. I can look back over my own experience, and can remember our shop giving prices for building a lathe. Very often the completed machine would represent the cost of actual production, and the usual profit, but there would be nothing allowed for the number of castings that were poured and broken up as being not good enough.

"Now, here is a line that will show how prices compare with the old days. As a rule 1914 is taken because it was in that year the war started, and everything dates from before or since the war. But figures I am giving are for 1910 and 1911. In 1910 a chucking and turning machine cost $1,200, and the present price is $2,010. Here is another style of the same machine, a little larger. In 1911 the price was $1,500 against a quotation today of $2,405. Then here is the 15-inch shaper that in June of 1911 would have sold for $390, and today is listed at $875. A 24-inch shaper that in 1911 brought $595 is today selling at $1,195. That is, as far as I can learn, about the rate of increase that has been made by the standard builders of the country. It is not out of keeping with the way in which everything has increased. Pig iron and steel have increased more than that. Not only has the price of the tool increased, but one must not forget that the standard and quality of the output has increased. We are making a better machine today than we were before. There are more attachments on it for good work. There may be reductions made, and I do not hold that they would not be desirable, but it would be a mistake to imagine that business is going to come back to the same poor level it had before the war. I can't see where it is desirable from any point of view, or where it would be to the lasting advantage of any person."

MANY REPLIES FROM CONTEST

Readers Are Showing a Keen Interest in Perusing Advertising Pages

A large number of answers have been received to the contest conducted by Canadian Machinery regarding the contents of the advertising pages, and the rules offered as prizes will be sent out in a few days.

A more comprehensive list is being prepared and will appear in the next issue of Canadian Machinery. Watch for it.

THE YEAR'S WORK AT SCOTIA MINES

Increase in Production Found in Comparing With Last Year's Figures

If increase in production is a dependable criterion, the earnings of the Nova Scotia Steel & Coal Company for the 1920 year will show a big gain over last year. Due to adverse market conditions the 1919 production fell off sharply as compared with the two previous years. That there has been an equally decisive recovery is indicated by the following figures (in tons):

	Nine months to Sept. 30.	
	1920	1919
Coal	456,312	387,151
Pig iron	63,632	26,697
Ingots	95,354	38,306
Blooms and billets	82,202	36,124
Merchant mills	44,859	27,864

Nova Scotia Steel last year on greatly curtailed output earned $5.73 a share for the $15,000,000 common stock, as against $5 paid in dividends. On this small number of common shares (150,000) the company this year is undoubtedly making a much more satisfactory showing, thus confirming the conviction of leading shareholders that their property is one of the most valuable participants in the pending British Empire Steel merger.

The city of St. Johns, Nfd., is to have a new 200-room hotel, costing $1,000,000, to be operated by the United Hotels Co. The capital invested is to be local capital.

A new garage is to be erected by the Consolidated Motors, Ltd., at Winnipeg, at a cost of $80,000.

MOTORS AND CORRECT APPLICATION

Continued from Page 465

tions that may be made in the motor by control of its design. Both of these points should be thoroughly understood and analyzed, before a proper motor application can be made.

Figure 1 herewith, shows the speed-torque characteristics of a standard polyphase induction motor. The upper one of the three curves shown is the speed-torque curve of a typical standard induction motor. In these curves, synchronous speed is taken as 100%, and the maximum torque that the motor will develop is also taken as 100%. The full-load torque—that is, the torque at which it will operate continuously without overheating—is only about 30% of the maximum torque. It will be noted that the full-load torque occurs when the speed has dropped to about 96% of the synchronous speed; that is, the slip is about 4%. If over-loads are applied, the speed continues to drop and the torque to rise, until the torque has risen to a value of a little more than three times that at full-load, and the speed has dropped to about 75% of the synchronous. Then occurs the so-called "pull out" point; that is, an attempt to pull still more load with torque causes the motor rapidly to come to a standstill because beyond that point the torque decreases rapidly with decrease in speed. This is accompanied by a rapid increase in current as is shown by Figure 3. This "standard motor" is provided with a low resistance motor and is the type of motor that is usually referred to as "standard."

If instead of a low resistance rotor, one is provided with approximately double the resistance of the "standard," the middle curve of Fig. 1 will apply. The speed-torque curve of the motor will be distinctly modified by this change in resistance. The slip for a given torque is much greater than in the "standard" motor. Instead of 4% slip with full-load torque, we now have nearly 10%. The "pull out" instead of occurring at about 75% syncronous speed, now occurs at about 30% synchronous speed. Also, the torque at standstill is nearly a maximum, and the current taken at standstill, as shown in Fig. 3, is considerably less than with the standard motor. In comparing these two curves, it is quite obvious that for work that requires large motor torques at speeds lying between approximately one-third and two-thirds of the synchronous speed, the motor with the middle curve is better adapted than the "standard motor." Also, for "fly-wheel" jobs—that is, where a fly-wheel does the work, and it is the duty of the motor to bring the fly-wheel up to speed again at its leisure, the middle curve is obviously the better, since it allows the fly-wheel to give up more than double the energy without bringing the motor to a given load, than in the case of a "standard" motor. For hoist work also, where heavy torques are necessary at start and the loss of a small fraction of speed under load is immaterial, experience has demonstrated that this type of curve is highly desirable.

If the resistance of the rotor is still further increased; that is, approximately doubled again, the lower curve of Fig. 1 applies. In this case it will be seen that the slip is still further increased, being about 18% at full-load torque, and that at standstill the torque is still increasing; that is, the "pull out" point is at some negative speed. This type of motor is applicable to cases where the maximum torques are required at standstill and at speeds up to 40% or 50% of synchronous. The elevator is a typical example of this duty. In this duty, the maximum torque is required at standstill since the friction of rest must be overcome at this point and, as is well known, the friction of rest in the typical elevator engine is several times that after the first few revolutions. The overcoming of this friction of rest and the acceleration of the car from standstill requires the maximum torque at low speeds in this application, and experience as well as theory has shown that this curve is best adapted for elevator work.

By using o Slip Ring motor the rotor resistance may be changed at will, and a motor of this type may be changed at will to meet any of the speed-torque characteristics shown in Fig. 1. In securing this advantage, however, we have been obliged to use slip rings on the rotor, thereby increasing the cost and reducing the reliability and ruggedness of the machine, but more important, we have very considerably reduced the maximum torque which the motor will produce. These disadvantages make it highly desirable to stick to the Squirrel Cage construction, if it is in any way possible, to fit any single speed-torque characteristic shown in Fig. 1 to the work to be performed.

Fig. 2 shows how the horsepower output of the three motors shown in Fig. 1 varies with torque. In considering these curves, we should bear in mind that the main part of the work done by the low resistance and semi-high resistance rotors are preferably close to the synchronous speeds, while the design of the high resistance rotor is such that it can do its best work at speeds below 50% of synchronous.

Fig. 3 shows how the amperes and power factor of these motors cary with torque. For a given torque, the amperes and power factor of any of the three motors is exactly the same.

However, the maximum amperes of the high resistance rotor machine at standstill is only about two-thirds of that of the low resistance rotor. The much higher torque of the high resistance rotor machine gives us at standstill a torque per ampere about three times as great in the high resistance rotor machine as in the low resistance rotor.

CANADIAN MACHINERY
AND
MANUFACTURING NEWS

VOL. XXIV. No. 22 November 25, 1920

Here Is One Method of Making Back Gear Parts

Can You Suggest a Better Plan of Producing These Parts? If so, We Want to Hear About It—The Author Merely States His Views Upon the Problem.

By G. BARRETT

RELATIVE to the manufacture of back gear parts these pieces could be made in various ways, using screw machines, Jones and Lamson bar turrets, semi-automatics, disc grinders, etc. However, we will take a Warner and Swasey for our lathe work, as it is particularly adapted to the work, and by the use of specialized labor would give very good results at the least cost of production.

In machining the lever, the first operation would be the facing of the two sides of the large boss. These pieces would be clamped on the indexing fixture, Fig. 1, the boss being supported by the V-block A, shown in the sectional sketch. This support is to take the strain of the cut of the straddle milling cutters B, the clamps C and D holding the lever firmly in position.

The bolts E work in T-slots and are used to clamp the upper revolving part of the fixture after indexing, thus keeping the fixture rigid while milling the boss. The advantage of this method is that one piece can be placed in position while work is proceeding on the other. The approximate output from this machine would be 16 per hour.

Second Operation

The second operation would consist of drilling and reaming the 3-4 inch hole in the boss which is accomplished in the jig, Fig. 2. The lever is held flat on the boss by the knurled bush A, which is just sufficiently tightened to bring the lower face square on the block B; then by means of the taper drift C, the lever is held up to the V-block D. The outer portion of the lever

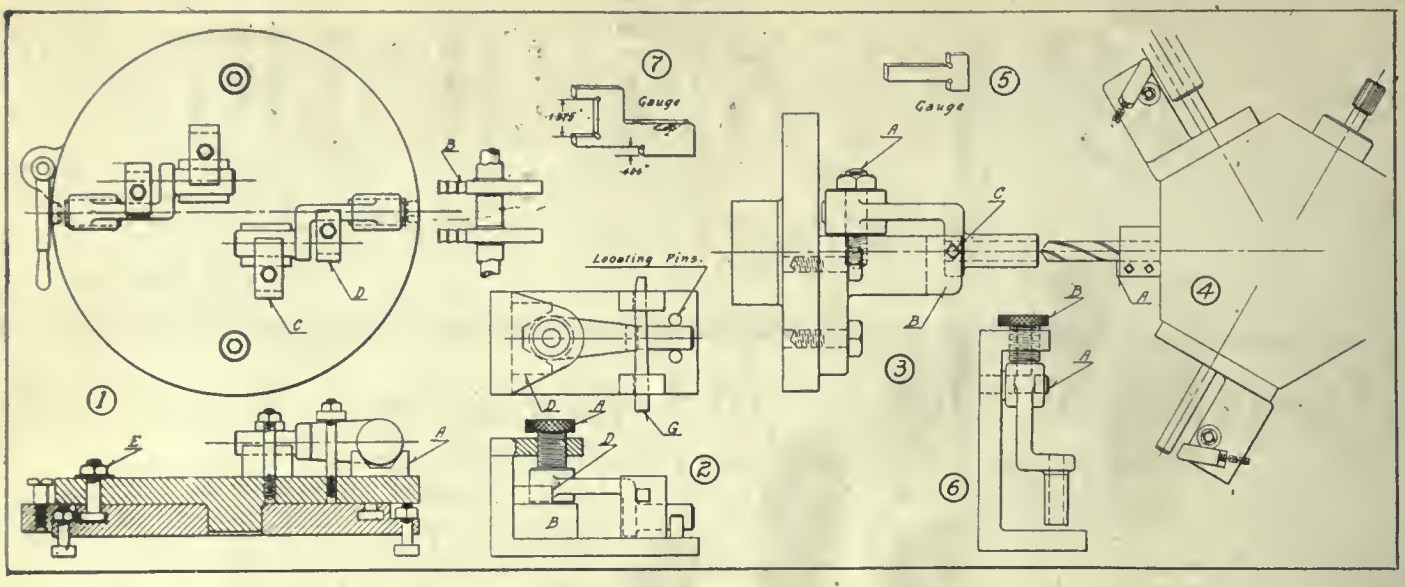
LOCKING PIN I WANTED C.R.S. PCE. # M 187
BACK GEAR SPINDLE BUSH I WANTED C.I. PATT. # M 33

HERE WE SEE THE VARIOUS DETAILS. STUDY THEM CAREFULLY.



THIS SHOWS ARRANGEMENT NO. 1, AND INCLUDES FIGS. 1 TO 6.

is centred by the two locating pins shown. The average production from this operation should be about 22 per hour.

The third operation would consist of boring and turning for the knurled grip. This would be performed on a turret lathe and held in position by the pin A, Fig. 3. The fixture used is a special casting and is held to the face plate by suitable cap screws. After being perfectly aligned the casting could be doweled, so that the same could be removed and replaced at a future date for quick and accurate setting. The fixture proper is slotted at B, leaving about 3-16 inch clearance for the offset in lever. This clearance is to provide for adjustment of irregular castings.

This detail is taken care of by two set screws, one on either side of the fixture. The first operation on the shaft portion is spotting the end and then drilling, using a straight shank drill, this being done to allow of close setting when using the facing tool A in Fig. 4. The gauge for this operation is shown in Fig. 5. We next rough turn the outside, leaving about 1-16 inch for finish. This roughing is done by means of a box tool, using Stellite tool bits. The next face of the turret would carry the reamer for finishing the hole to size. The next detail is the finish turning of the outside. The time required for these operations would provide for an output of about 100 per day of nine hours.

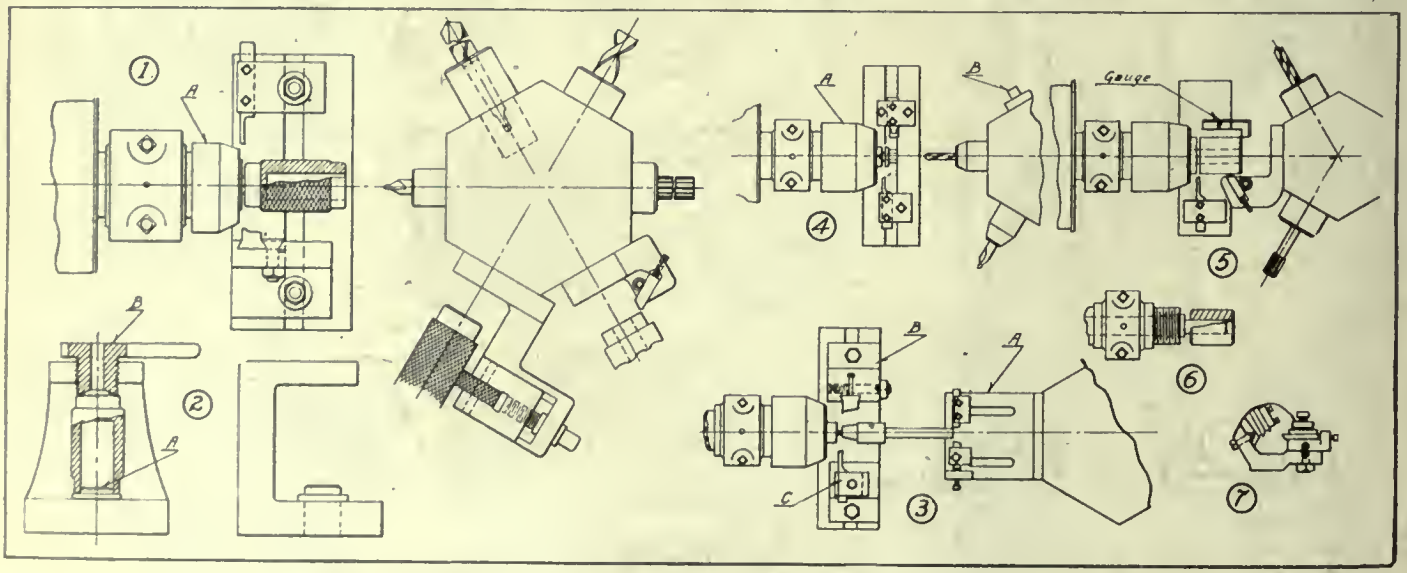
The final operation on this lever would be that of drilling the 1-2 inch tap hole in the boss. The jig for this is shown in Fig. 6. The drill bush acts as a clamp for holding the work while drilling. Two of these jigs are used, one for drilling and one for tapping. Production from these jigs would be about 300 per day.

Knurled Sleeve

The knurled sleeve is made from cold rolled stock of the required diameter, the bars being held in the collet chuck A, Fig. 1 in arrangement 2. This piece has eight operations, comprising centering, drilling, squaring bottom of hole, reaming, turning clearance for knurl, knurling the body and drilling the end and pin holes. The lathe setup is shown in Fig. 1. The 5-16 inch hole is drilled in the jig Fig. 2, the machined end resting on the plug A and the upper end held by the drill bush B. The lathe would produce about 50 per day and the drilling would account for approximately 250 per day.

Work on the locking pin is shown in Fig. 3. This pin would require three operations on the 5-16-inch shank. Box tools are used for the turning of the stem, three of them being used for taking off different amounts of stock. The tapered end of the pin is formed by a special tool fitted to the rear of the cross slide. The piece is then parted off by the front tool C. The production would be about 200 per day.

The small retainer bush is made from 15-16-inch cold rolled steel, using the collet chuck on the lathe spindle A in



ARRANGEMENT NO. 2, SHOWING WORK ON THE KNURLED SLEEVE.

Fig. 4. The stock is fed through the spindle to the stop B, and then drilled to the required depth. The tool on the rear of the cross slide is then used to turn the small diameter, after which the piece is cut off by the parting tool in the front holder. About 400 per day should be made on this operation.

The spindle bushes are made of cast iron, cast in lengths of about 2 feet, roughed out to within 1-16-inch of the finished size, and then placed in the turret lathe where they are drilled, reamed and finish turned and cut to the required length, as shown at Fig. 5. The possibility of a burr on the inner end would require the pieces to be placed on a separate arbor and the end faced off, as shown at Fig. 6. The first operation would give a production of about 150 per day and the facing would produce about 90 per hour.

Machining the Sector

To machine the sector the piece would be gripped by the hub in the two jaw chuck Fig. 1, arrangement No. 3. The sector is drilled, reamed and faced, using gauge B. The facing tool C is made from bar stock with inserted blades and pilot. About 200 per day should be got from this operation. The next operation is drilling and reaming for stop pins. This is done in a box jig Fig. 2, the sector being centered from the hole already bored and held against locating pin A by the pointed set screw B. This pin is used to bring the lugs on the sector to the proper position from the centre of the stop pin holes.

After tightening the set screw the sector is held by the taper drift C. The drill bushes are made a slip fit so as to be renewed while reaming holes. For this operation we use a two spindle drill, one spindle carrying a drill and the other the taper reamer. Output about 300 per day. The final operation on the sector is shown in Fig. 3. This is the turning of the hub. This is done on a lathe fitted with a hardened steel arbor A, inserted and ground to fit the hole in the hub. The special face plate B is made to accommodate two set screws C and D, which are located in the desired position to screw into the stop pin holes. These set screws need very little tightening in order to hold the work. The facing tool E has a hardened steel pin inserted and set to the required distance from the cutters. The output from this operation would be about 100 per day.

In the making of all these parts it is essential that every operation be accurately performed to avoid trouble in succeeding operations.

In my estimation the cost of these jigs and fixtures would be around $400, and this figure would mean a considerable saving in the first 1,000 plates.

A safety device for punch presses, developed at the works of the Ford Motor Company, makes it impossible for the workman to get his hands in the way of the plunger. To operate a press thus equipped the workman must press two buttons about a foot apart, so that it is necessary for him to use both hands. A two-man press so equipped will not trip until four buttons are pressed at one time; a three-man press will not trip until six buttons are pressed simultaneously. According to a director of the company, the device has not only practically eliminated punch press accidents, but has increased production on an average of 10 per cent., owing to eliminating the fatigue resulting from the operation of punch presses by a foot trip. All punch press operators are required to use tongs for inserting metal and taking it out of the presses.

INTERESTING CATALOGUE

The Canadian Blower and Forge Co., Ltd., Kitchener, Ont., have issued a new catalogue, No. 19C, dealing with their varied line. This includes forges, blowers, exhausters, fans, drills, punches, shears, binding machines, tire setters.

Combination wood working machines, fan system apparatus for heating, ventilating, drying and mechanical draft, air washers, humidifiers, dehumidifiers, pumps, etc., etc., are also shown. This book contains 186 pages of real, live information to those interested in such lines.

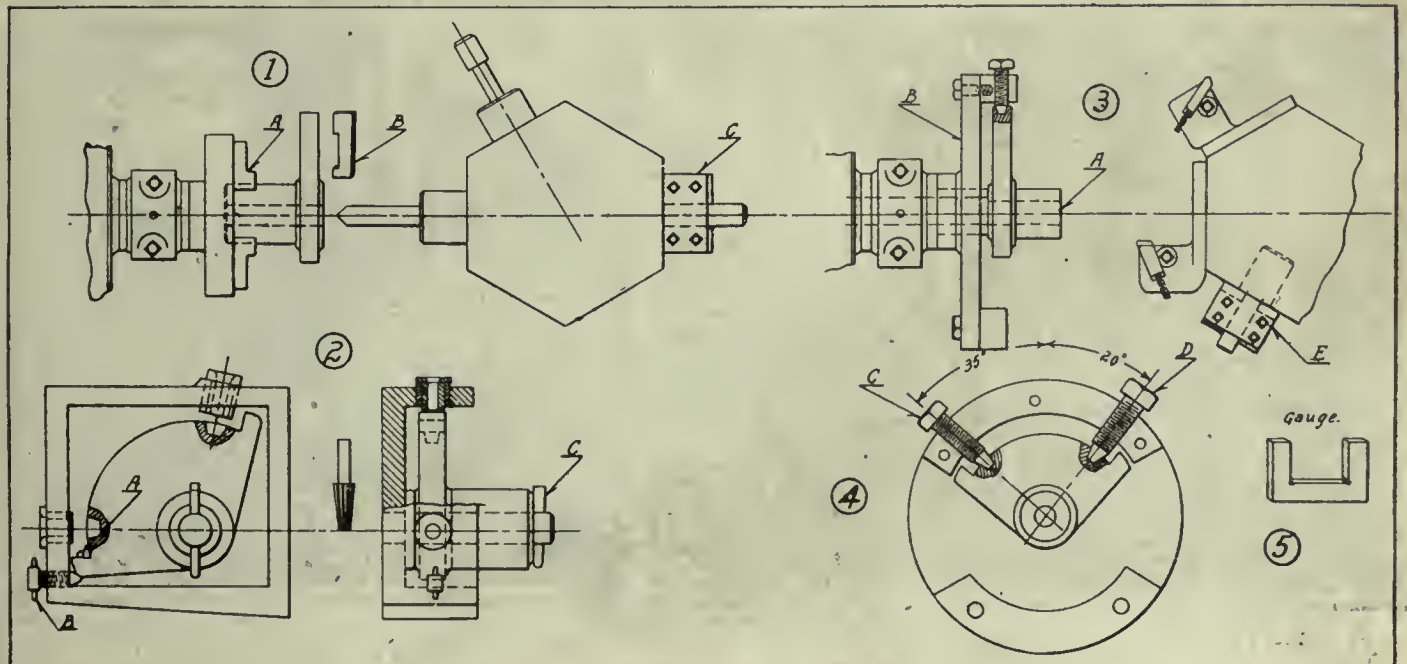
NEW CATALOGUE

The Machinery Co. of America, who are distributors for Baldwin, Tuthill & Bolton, Covel Mfg. Co., and Hanchett Saw Works, have issued a very nice catalogue dealing with the lines mentioned above.

These include saws, automatic band sharpeners, saw sharpeners and gummers; roll stretchers, saw stretchers, lap grinders, brazing clamps, saw brazing forges and shearing and cross cutting machines.

Other lines shown are filing clamps, stands for band saws, patch machines, band wheel grinders, segment grinders, band saw swages, swages of all kinds, swage shapers, swage hammers, gauges of all natures, knife grinders, two-wheel grinders for high speed steel knives, balancing machines, and other innumerable lines, 224 pages in all being shown and well illustrated throughout.

The American Mining Congress economist states that gold production has declined from $101,000,000 in 1915 to $58,500,000 in 1919, and probably will be $40,000,000 in 1920.



ARRANGEMENT NO. 3—METHODS EMPLOYED IN MACHINING THE SECTOR.

Do You Safeguard Your Existing Equipment?

Accidents Can Be Reduced to a Minimum by Guarding Moving Parts of Your Machine Tools—This Applies Especially to Existing Equipment, Which May Have Been Manufactured Before Guards Were Considered Essential.

By J. H. MOORE.

THE splendid results accomplished by safety engineers within the past few years have shattered, beyond shadow of a doubt, the old fallacy that accidents occurring while at work were necessarily incidental to industry. No longer do we believe that a certain percentage of casualties is inevitable.

Not only has it been shown that accidents are preventable, but that, apart from being the humane thing to do, the very prevention has been profitable to the firm concerned. Take, for example, the power press. This type of machine was responsible, year after year, for the maiming of thousands of employees, and the position of press operator was an exceeding hazardous one. But conditions have changed since the installation of efficient guards, and at the present time a tour through any up to date press room is a pleasure. Should an operator lose a finger these days the cause can usually be traced to rank carelessness on his part.

These same conditions exist in many other lines of industry, and machines in general are better guarded than ever before. Mr. H. A. Schulf, of the U. S. Steel Corporation, speaking upon the subject of safeguarding machinery at its sources, remarked as follows: "We have but to turn to the advertising pages of our technical journals, where page after page shows machines pictured with hazardous points guarded. True, the guarding is not always adequate, some parts being exposed that shouldn't be, but we cannot afford to be too critical. Think of the advertising pages of 10 or 15 years ago. In those days the gears, power transmission, etc., were devoid of any covering."

It is obvious that the best time to safeguard a machine is while it is being designed, for we can then incorporate the features essential to safety, at the same time producing a design that is pleasing to the eye. This, however, is impossible in the case of machinery built 10 years ago, but that fact need not deter one from installing guards on these early models. True, they may not look quite as neat, yet neatness is a secondary consideration alongside of safety. The chief point to watch is this: Make the guards as complete as possible, and of good stout construction. A frail guard never was a success.

Safeguarding Existing Equipment

To illustrate what can be accomplished in safeguarding existing equipment we have selected four views from the plant of the International Harvester Co. at Hamilton, Canada. This concern has made a very careful study of the safety question, and have at each of their plants various safety experts who make it their chief business to design and instal adequate guards in all departments.

It is, of course, impossible to show even a small percentage of these guards, but we have contented ourselves with the four views depicted herein. Take for example Fig. 1. This photograph shows a portion of one of the aisles running through their woodshop. Note the guards at every machine, each being of a standard style. This is a feature well worthy of consideration, because by so doing they reduce the expense in making. In some cases the guards are made in standard sections, then bolted together as required. The aisle space in this photograph was not specially prepared for the occasion, but represents how the aisle is kept clean at all times. There are no chips, shavings, or dust to be seen, and the reason is self-evident. Every machine is equipped with dust and shaving removers, the material being sucked up the pipes, going from there into a huge hopper.

Fig. 2 illustrates a close up view of one of these guards, and its construction can be clearly noted. The framework is 1¼-in. angle iron, while the lattice work is usually ⅛-in. to 3-16-in. thick, and ¾-in. to 1-in. wide. Note that certain portions of these guards are hinged, so that they swing out to allow repairs to the machine if necesary. A castor is placed at the bottom of the legs in some instances, as for example at A and B in the present photograph. The method of holding these sections in place is the same as used on any gate, and this part can be noted at C.

FIG. 1—NOTE THE CLEAR AISLE SPACE AND WELL-PROTECTED MACHINES.

FIG. 4—ONE STYLE OF EMERY WHEEL GUARD AS ADOPTED AT THIS PLANT.

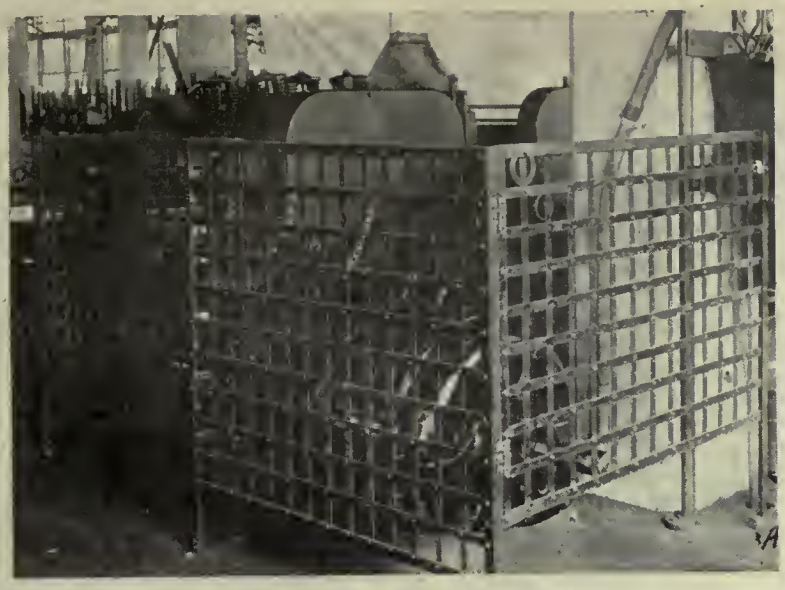


FIG. 2—CLOSE-UP VIEW OF ONE OF THE GUARDS.

The third example, Fig. 3, depicts a safety device installed on a rip saw. This particular work is of the following nature: The board and its proportions can be clearly seen. In the centre of the board there is a slot, but only for a certain length. This means that the saw has to be fed up vertically into the board after it has been placed in proper location to the saw. Before the installation of this guard, accidents were frequent, but by placing the device on the machine no further trouble has occurred. The complete attachment cost but a trifle, yet its results are satisfactory in every way. While on the subject of expense, it might be well to state that it is not always the most expensive guard that is the best.

The chief aim in the design of any guard should be simplicity. It stands to reason that the simpler it is the less expensive it will be, and this is not the only advantage. Give a workman an intricate, elaborate safety device, and he will distrust it. He will swear that it holds back production, and will have every possible excuse why he should not use it.

On the other hand instal a simple, yet efficient guard, explain the reasons for its installation, then watch the difference. It pays to take the workmen into your confidence. This statement may sound unreasonable to some, yet to prove its truth we quote the following experience of a large institution that decided to go into the matter of safeguarding all their presses. Their accident toll was very heavy, and they were, to say the least, worried about it.

Believing that what they did with their equipment was entirely their own business they proceeded to design and instal guards on all their machines. Imagine their surprise to find that the employees practically refused to use them, contending they would hinder production, thus reducing their wages. The development of this attitude was entirely unlooked for, and things were at a merry pass until the manager struck on the happy idea of getting the employees together for a heart-to-heart talk.

This was done, and at the talk he explained why the safeguards had been installed. Figures were quoted to show the extent of the accidents and the dire need of reform. "The idea is not a selfish one," he said, "but one that is for the workers' particular benefit. It cost real money, and lots of it, to put these guards in place, and our chief desire is to lower the accident hazard. Production will not decline, but will actually advance by the addition of these guards if you give them a fair trial. The very fact of their being there gives you confidence to work, knowing the punch cannot catch you unawares."

To make a long story short, the employees, approaching the matter in an entirely different spirit, found that what the manager had said was true, increased their production, and even went so far as to offer suggestions for further guards and improvement. Thus by taking the workers into their confidence this concern reduced their accidents from 120 to nil in one year.

Saw Guard

To proceed, however, to a description of Fig. 3. A is merely the gauge to which the work is held and there is another stop, not shown on the photograph, to locate work in opposite direction. B is simply a box inverted to protect the worker from the rising saw. The workman places the board to both gauges, presses his foot on lever shown, and up comes the saw.

An elaborate fixture on this work would have been superfluous, but by keeping to simple bounds the task is accomplished at practically no expense worth speaking of.

The last example, Fig. 4, depicts one of the styles of emery wheel guards adopted at this plant. They are of the dust-removing type, being connected up to the exhaust system in the usual manner. The guard is entirely home-made, and while not very classy to look at, or very elaborate in design, it accomplishes its purpose.

We leave the article at this point, not because the subject has been exhausted, but in the belief that sufficient has been shown and said to start the germ of thought working. Think to yourself, "Is there any machine in our plant that needs guarding?" Then, if there is such a machine, get it protected before it slips your mind. Accidents always remind us of this need, but it is better to lock the stable door before the horse departs.

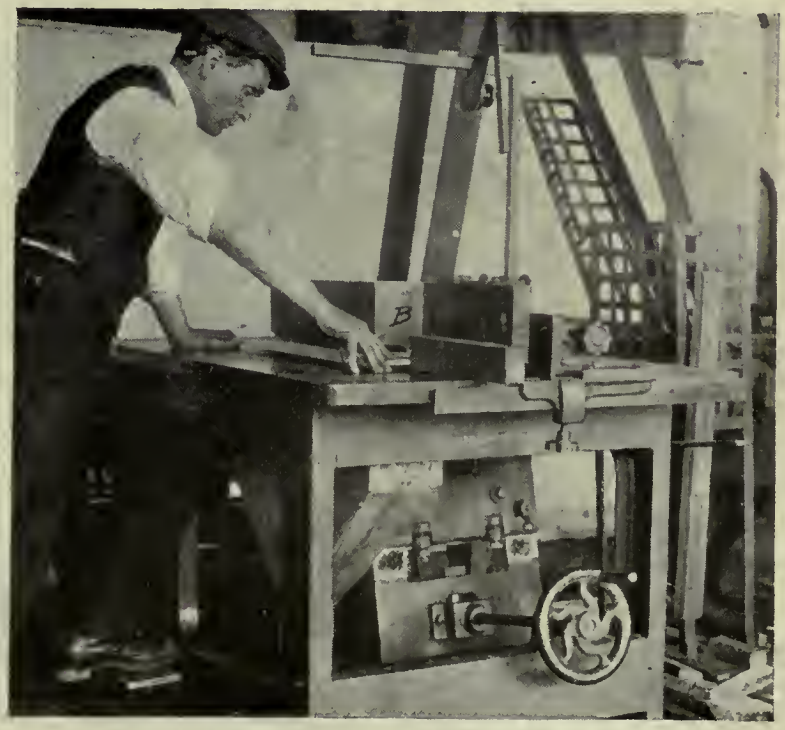

FIG. 3—A NOVEL AND SIMPLE FORM OF SAW GUARD.

Hardening Screw Gauges With Least Distortion

How to Harden Screw Gauges With the Least Distortion Along the Pitch Line—That Was the Problem Confronting the Above College, and Herein is Explained How the Work Was Accomplished

By WILFRED J. LINCHAM, Goldsmith's College, London.

THE first law of hardening (known for many years) asserts that sudden quenching after heating retains the steel in the condition that prevailed at the quenching temperature.

The second law of hardening (of much more recent discovery) states that quenching, while crossing an arrest or recalescence point, produces the least amount of distortion, and it is one of the purposes of this paper to endeavor to prove the truth of this law. A second reason for the paper is to offer the author's results to other screw-gauge manufacturers for their immediate assistance.

The second law had already been used by other investigators and practically applied with material success, but the author was unaware of the exact researches that have led to the adoption of fixed temperatures. The Wild-Barfield process he believed to be the first practical example, the principle of which is to use the change in magnetic properties of wrought iron or steel when passing from the β to the α state to indicate the temperature at which to quench. Reference to the Roberts-Austen diagram, Fig. 1, shows this to occur along the Ar2 line, temperature 765 to 770 deg. C. (1,409 to 1,418 deg. F.).

The Horstmann Brothers arrived at a similar result by quenching at 700 deg. C. (1,292 deg. F.), which is the temperature of the eutectoidal line Ar1. The screw gauges they manufactured were produced, they said, with no alteration in pitch, but a slight swelling always occurred in diameter, which was lapped down afterward. They kindly communicated their method to the author, who thereupon decided to make his own investigations, the results of which are now set forth.

The author's first-sought ideal was a quenching temperature which would produce no distortion whatever, but it will be seen that this has not been achieved, nor does it seem likely that anything more than a minimum distortion can be arrived at. The Ar1 line for the use of the second law appeared to have manifest advantages over that at Ar2 because of its constancy of temperature over a large range of carbon percentages; and it seems reasonable to expect that steels of any carbon content will act in the same manner when cooling across this line, if all are free from impurities.

Before the war the manufacture of screw gauges was confined to the use of high-carbon steel, say, from 0.85 to 1.2 per cent. carbon, which was usually left unhardened, on account of the difficulties caused by distortion on quenching. The making of hardened screw gauges had been practised to a very limited extent before 1914, the correction after harden-

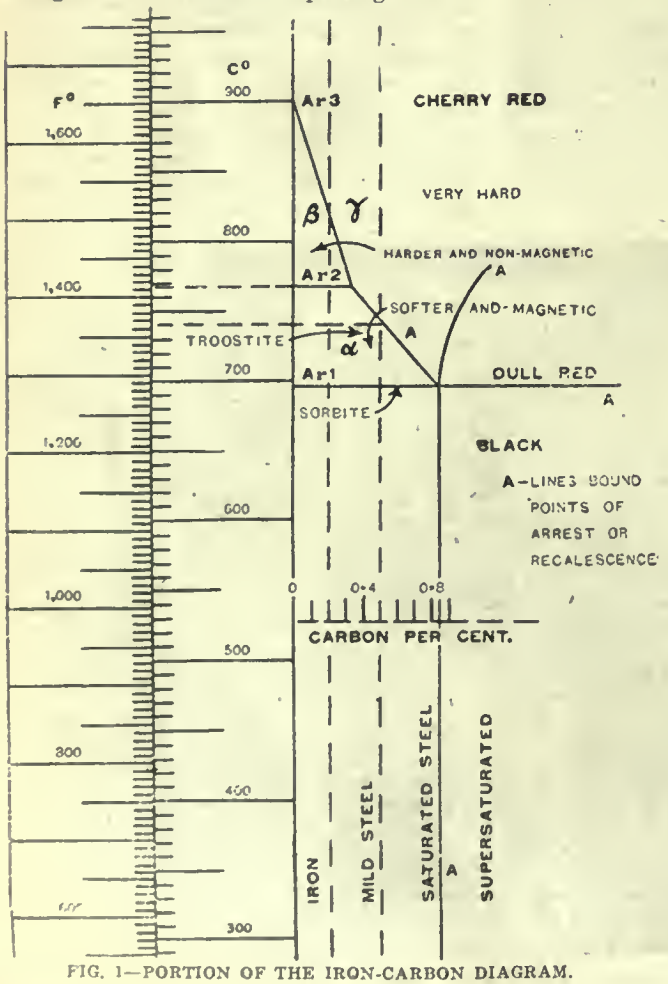

FIG. 1—PORTION OF THE IRON-CARBON DIAGRAM.

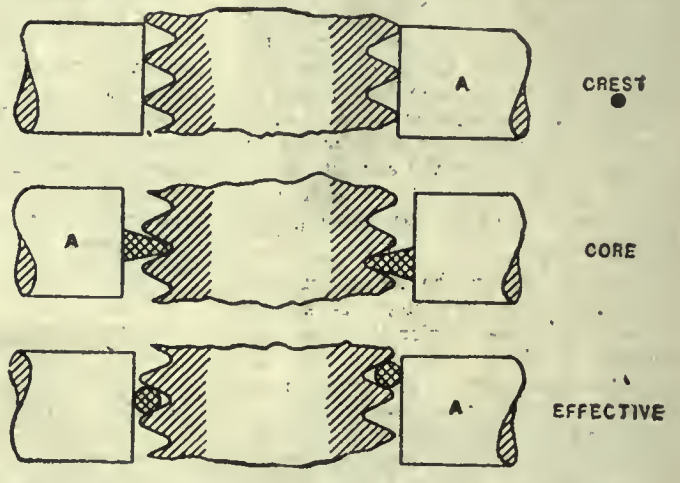

FIG. 2—MEASUREMENT FOR DIAMETER AAA—MICROMETER ANVILS.

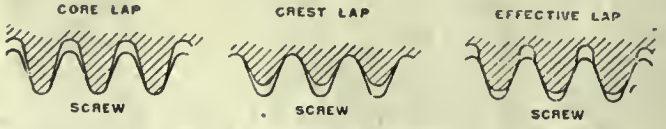

FIG. 4—LAPPING THE SEPARATE ELEMENTS OF A SCREW.

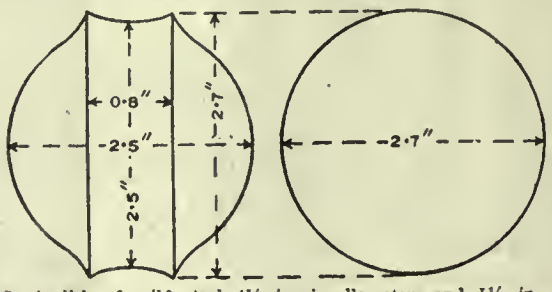

Fig. 5—A disk of mild steel 4¼ in. in diameter, and 1½ in. thick originally was swollen as shown by means of 1000 successive heatings and quenchings. Original volume 21.28 cub. ins. Final volume 21.00 cub. ins.

ing being obtained by the use of laps of cast-iron or boxwood. The method taken generally has now been revived and extended, and is the only one followed at the present time, so a short description will be useful in order that the author's intentions may be understood.

Assuming that the gage can be hardened with so little change that the pitch tolerance, plus or minus, is not exceeded, which it will be shown can be done, the process of making a gage involves, first, the accurate screwing of the blank, and then hardening the screwed piece.

The first was carried out in a lathe accurately corrected in pitch by a cam bar. The screwing tool, known as a form tool, was of disk shape and supplied with chasing teeth on its circumference. Two of these "form chasers" were used, both being quite accurate in pitch and of perfect sectional contour for the thread to be cut. One was used to rough out the gage screw to about half or two-thirds the thread depth; and the other, very carefully adjusted in position, to finish the thread correct on core, crest and effective diameters and full form. Constant measurement was, of course, necessary, but as the lathe slides were provided with micrometer disks, rapid and almost automatic manufacture was soon secured. The intention of the author at this stage of the work was to just clean up the gage with a full-form cast-iron lap, accurately made from a tap cut in the before-mentioned lathe. This method of lapping proved a failure, the abrasive clinging to the soft gage and causing "scoring," so he fell back on the cutting tool itself for the accuracy demanded, assisted by the use of a very mild steel of 0.14 per cent. carbon for the blanks that cut with a polish. The object of the screwing operation was to produce a gage that was perfect in all dimensions while yet in the soft state.

The next step was to harden. The hardening of screw gages, and, indeed, some others, was performed in a cyanide furnace, made by John Wright, of Birmingham, which consisted of a rectangular cast-iron bath, covered and ventilated to remove the fumes, filled with sodium cyanide, and heated by coal gas and air, the latter being fed at a pressure of three pounds per square inch. The cyanide, which melted at about 600 deg. C. (1,112 deg. F.) and boiled at or near 800 deg. C. (1,472 deg. F.), was maintained at 750 to 770 deg. C. (1,382 to 1,418 deg. F.) when in use, the temperature being indicated by a thermo-couple pyrometer. The gages (of mild steel) were placed on trays suspended clear of the bottom of the bath and soaked from ten minutes to one hour, according to size, or until they had acquired the requisite depth of case.

The Cyanide Bath

If a greater depth of case than 0.005 in. be required, packing the gages with barium carbonate and bone black in closed boxes and soaking in a muffle furnace at about 850 deg. C. (1,562 deg. F.) must be resorted to, but the final heating should be completed in the cyanide bath.

It is possible to allow the cyanide bath to cool to the quenching temperature (supposing that to be exactly known) after the requisite soaking of the gage, but the process absorbs much time and increases expense, and is not to be advised for continuous working. Also the temperature may be ascertained by the color of the gage, which may be taken as a very dull red, but this is not advisable. The author therefore installed, in addition to the cyanide bath, a Brayshaw salt-bath furnace, using "pyromelt," and kept that furnace at the constant quenching temperature. This furnace was called the "store furnace," for when a gage had had its full time in the cyanide it was stored here at quenching temperature until its heat had evened up; and it was afterward quenched at leisure. The quenching tank was close to the store furnace and of ample capacity, with inflow and outflow cocks.

The screw gage was next measured for pitch and diameters. The diameter measuring machine has already been illustrated in the Proceedings, 1917, page 54, and Fig. 4, page 55, and the mode of its use is merely suggested in Fig. 2 (page 5), which shows the micrometer anvils at the moment of measurement.

The Pitch-Measuring Machine

The pitch-measuring machine, Fig. 3, was designed by the National Physical Laboratory and constructed at Goldsmith's College. The drawing is somewhat diagrammatic in order to show the principle clearly. The gage is supported between centres on the main or fixed casting. A movable carriage supports an indicator on the left and a micrometer on the right, being always pressed leftward by means of a weight. The indicator carries a stylo, which engages with the screw thread, and a pointer in connection therewith, whose reading is

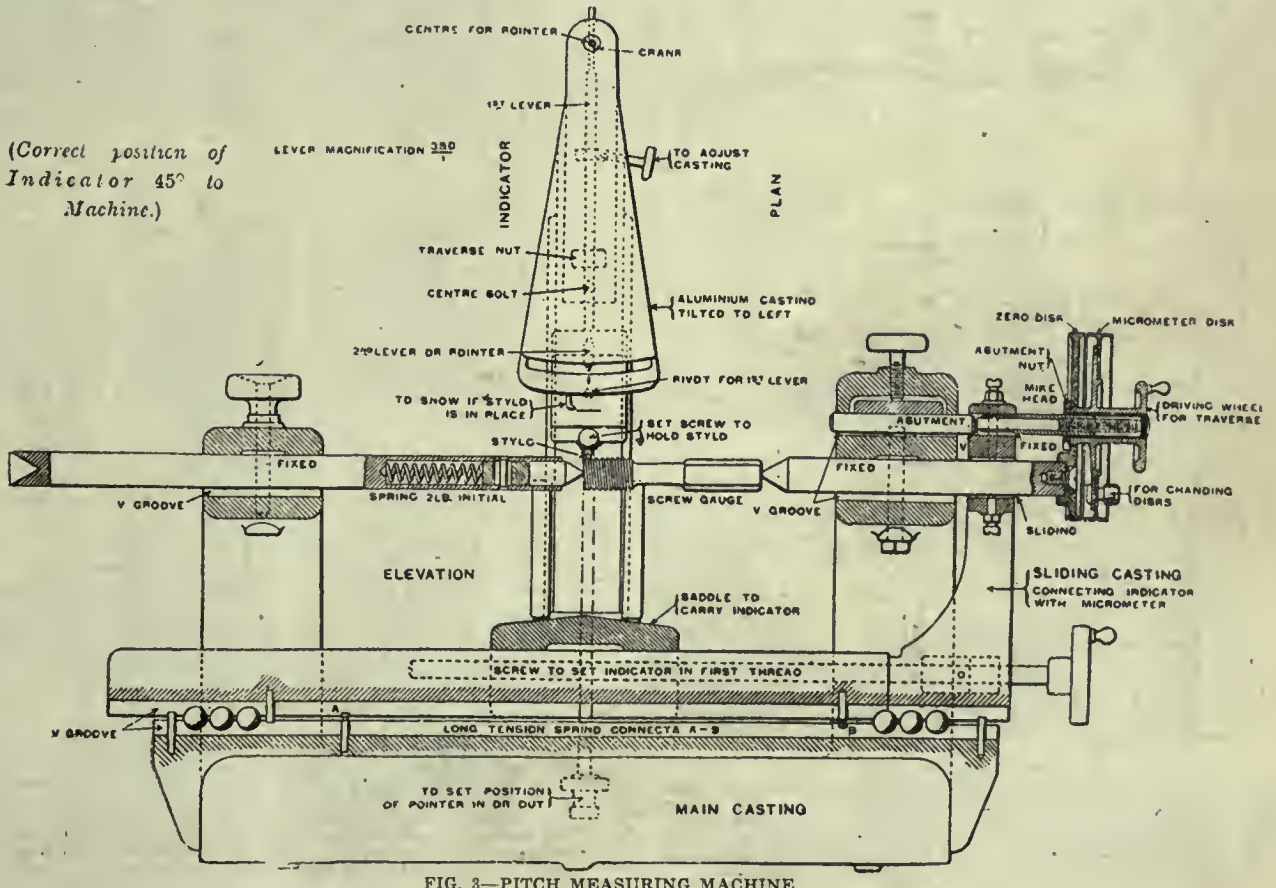

FIG. 3—PITCH MEASURING MACHINE.

multiplied so as to be in the region of one-millionth of an inch of sensitiveness. The micrometer abuts against the main casting and can be read to 0.000001 of an inch and very rapid charting of screw errors can be obtained.

After hardening, it was found that the screw pitch had not distorted beyond the tolerance, plus or minus, if precautions had been taken such as suggested later. The diameters, however, had increased, at least the core and crest were larger, but the effective surface was often unchanged. The operation of lapping followed, three laps, Fig. 4, being used; but the enlargement being only about 0.0001 to 0.0003 in. in diameter, the amount of lapping was very little. Naturally the operation was of a delicate character, and was the particular part of the whole process that most held up delivery; many gages were spoiled in its exercise; but it is believed that the whole hardening process will yet be so perfected that only a full-form cleaning lap will be necessary.

Gages Examined by Optical Lanterns

Finally each gage was examined by an optical lantern magnification of exactly 50 to one, as already described in previous papers; and, of course, the pitch and the diameters at all three elements of section were thoroughly tested during the stages of manufacture and just before delivery, by a competent staff of examiners. It will be said that if only a screw gage could be made to travel through its various manufacturing steps in such a simple and well-oiled manner, the difficulties of screw gage making would be completely overcome. It is one intention of this paper to show that the difficulties of manufacture are being overcome by the adoption of definite scientific method, and there are strong and practically certain hopes of doing away with lapping altogether.

The crucial point of the manufacture is the hardening. Lathes have been specially built that will produce accurate pitch, and mild steel is being used that can be finished in those lathes with a polish. It will be shown that a quenching temperature can be found that only lengthens the pitch by 0.0002 in. over 0.7 in. of length, which is within the pitch tolerance, 0.0003 in., on such a length for inspection gages of correct effective diameter.

Two remarkable examples of distortion are shown. The first, Fig. 5, was, before treatment, a cheese-shaped disk of 4¼ in. diameter by 1½ in. thickness, of common mild steel. It was heated in a coke fire and quenched in water, the operation being repeated about a thousand times. The continued distortion has swelled the disk into an approximate spherical form, but that the volume is unchanged was ascertained by displacement measurement.

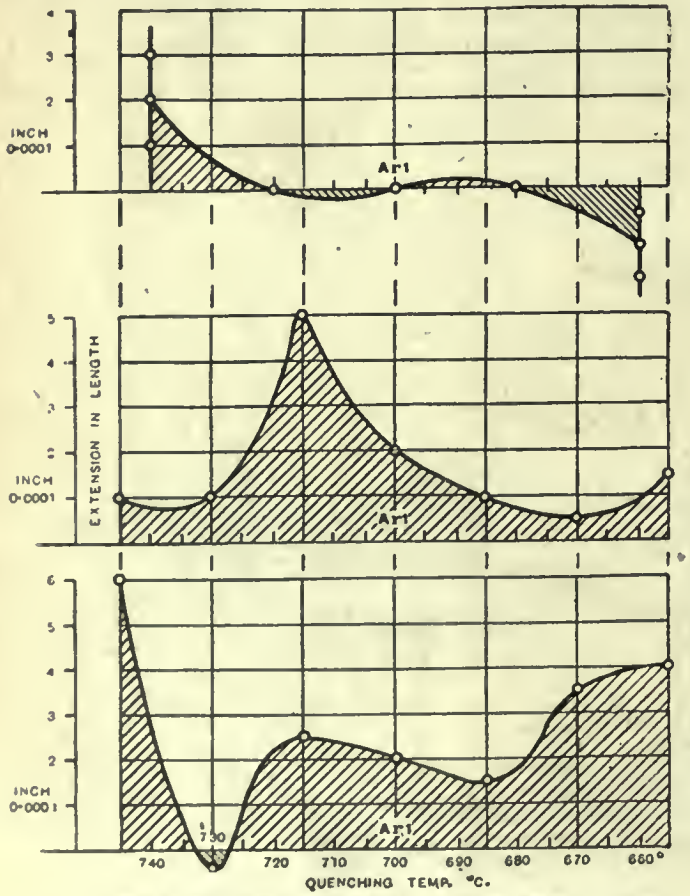
The second specimen, Fig. 6, was at first a rectangular disk, and here again the spherical form is attempted, the treatment being the same as in the first example.

These two specimens came to the author as a piece of exceptional good fortune, being presented by F. A. Thompson. Their history is: A garage boy required buckets of hot water at meal times and kept three of these pieces hot on coke fires, using which he pleased to heat the water by immersion, and continuing his unintentional experiments over a period of about a year.

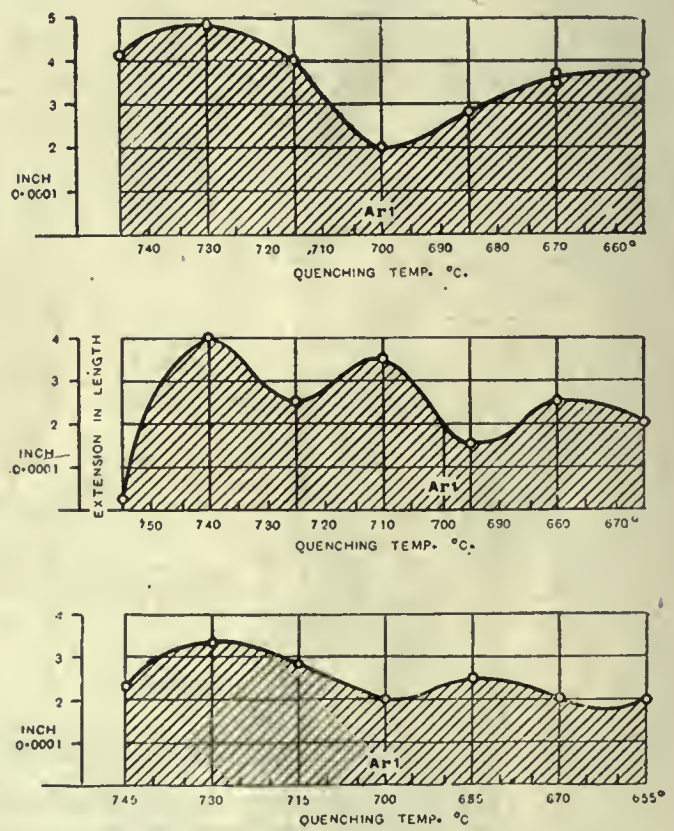
The author commenced his experiments in April, 1918, by providing seven specimens for each experiment, the material being J and L steel of 0.14 per cent. carbon. Each specimen was ground and carefully surfaced by stoning the ends, and the dimensions were about 9-16 in. in diameter by 0.7 in. long. Previous experiments upon pieces of full gage shape showed the wisdom of using simple cylinders for the temperature tests so as to obtain symmetrical distortions.

One form of distortion resulting from hardening a cylindrical piece of steel was found to be a swelling or bulging at the ends, but the length, measured at the edges, remained very little changed indeed.

The experiments were begun without any clear notion of the form the dis-



Figs. 7, 8 and 9—Experiments on distortion of screw gages in length only: viz.: On pitch line. J and L mild steel 0.14 per cent. carbon. Cased in sodium cyanide for 30 min. at 750 deg. C. Specimens 9-16 in. in diameter by 0.7 in. long. Fig. 7—Average change of length (measured over the end surfaces). Fig. 8.—Distortions all extensions. Fig. 9.—Curve which seemed to indicate no fixed law.



Figs. 10, 11 and 12—Experiments on distortion of screw gages in length only: Viz.: On pitch line. J and L mild steel 0.14 per cent. carbon. Cased in sodium cyanide for 30 min. at 750 deg. C. Specimens 9-16 in. in diameter by 0.7 in. long.
Fig. 10—Curve which indicates that 700 deg. C. (1,292 deg. F.) is the best hardening temperature. Fig. 11—Wavy curve with minimum at 795 deg. C. (1,283 deg. F.). Fig. 12—Minimum at 700 deg. C., but also at three other temperatures.

tortions were likely to assume, and axial measurements were at first made, which proved to be wrong for the purpose required. Also the ends of the cylinders were not parallel to less than 0.0001 in., and the average dimension was taken in the hard and in the soft states respectively. When, however, the circumference was divided into three or four parts and marked, and the change of length taken at the marked positions only and afterward averaged, quite consistent results were obtained, the figures fairly representing pitch line distortions on a screw gage.

Figs. 7 to 12 show, for six sets of experiments, changes of length in units of 0.0001 in. plotted on a base of quenching temperature.

Fig. 7 (April 5, 1918) is a record of the average change of length measured over the end surfaces, and contains the axial bulging. It was on this set that the bulge was first noticed, and from this time onward measurements were made on the edges only. The temperature of 700 deg. C. (1,292 deg. F.), however, is indicated as that of no distortion.

Fig. 8 (April 24, 1918). The distortions are all extensions, and 670 deg. C. (1,238 deg. F.) indicates least distortion. Several screws were hardened at this figure with success.

Fig. 9 (April 27, 1918). This curve was distressing. It seemed to show that there was no fixed law and that nothing would result from the labor. The figure 685 deg. C. (1,265 deg. F.) was taken as best, for the drop at 730 deg. C. (1,346 deg. F.) might not be trustworthy.

Fig. 10 (May 4, 1918). A good curve showing 700 deg. C. (1,292 deg. F.) to be decidedly the best temperature. Two specimens were quenched at 670 deg. C. (1,238 deg. F.) and are shown to fairly agree.

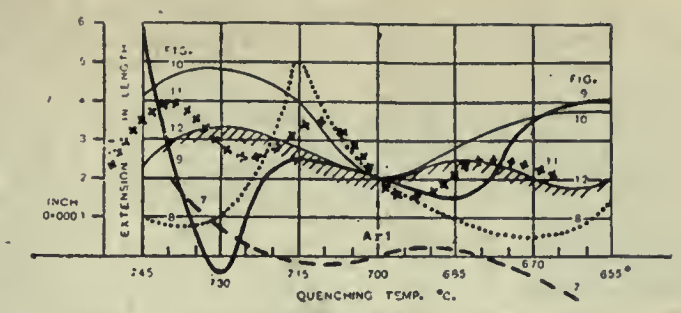


FIG. 13—SUPERPOSED CURVES OF FIGS. 7 TO 12.

Fig. 11 (May 9, 1918). Another wavy curve, with minimum at 695 deg. C. (1,283 deg. F.).

Fig. 12 (May 11, 1918). There is here a minimum at 700 deg. C. (1,292 deg. F.), but also at three other temperatures.

The problem, which now appeared hopeless, suddenly cleared itself. It occurred to the author to plot all the curves on one sheet by superposition, as in Fig. 13, and this operation was at once fruitful in showing that the distortion, or, as it may now be called, extension, had definite laws and was not the result of mere chance. Disregarding the first curve shown dotted, all cross at exactly one point, namely, 700 deg. C. (1,292 deg. F.), the recalescent point Ar1 of the equilibrium diagram. The extension is, unfortunately, not obliterated, but it has a fixed and definite value of 0.0002 in., and is within the tolerance limits. It indicates a condition of stability, and if 700 deg. C. (1,292 deg. F.) be made the quenching temperature, this extension can be allowed for when cutting the screw.

Other parts of the curves show nothing but instability. The use of the position 700 deg. C. (1,292 deg. F.) therefore is calculated to assist correct manufacture, while all the other temperatures are unreliable. On that account, an attempt to find a stable temperature of maximum extension, for use when needed, was practically unsuccessful; for gages quenched at 715 deg. C. (1,319 deg. F.) did not always extend well. A very important point is that the temperature must be found with accuracy, the range of stability being so very limited.

In Fig. 14 the distortion scale has been magnified and plotted for a range of 15 deg. ± of 700 deg. C. Maximum instability occurs at 715 deg. C. as well as maximum distortion, and in all cases temperatures below 700 deg. C. are safer than those above. A fair and safe latitude for quenching lies between 690 deg. C. (1,274 deg. F.) and 700 deg. C. (1,292 deg. F.).

The author found no difficulty in making sure of 700 deg. C. with the use of a platinum-rhodium thermo-couple, a thermometer within a galvanometer-case giving warning of any change of temperature of the cold junction. Upon retesting the thermo-couple after about six months' use it was found by the makers to be quite accurate.

It now appears that the second law of hardening proposed at the commencement of this paper is proved so far as the line at Ar1 is concerned, and could no doubt be proved for other arrest points.

In the early stages of this research

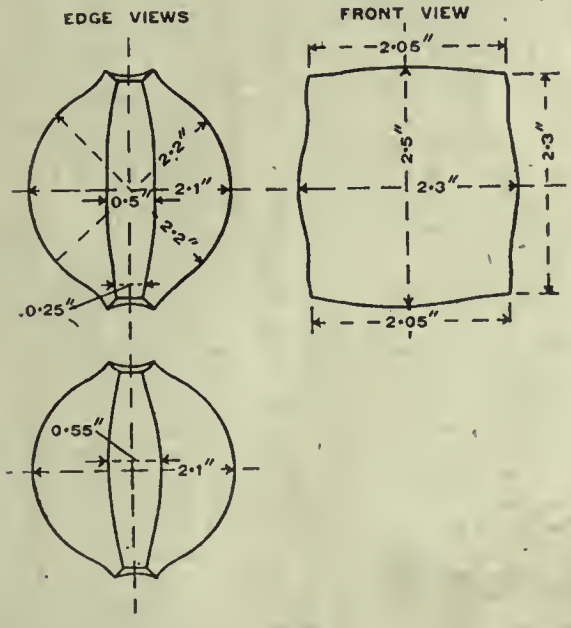

FIG. 6—RECTANGULAR DISK OF MILD STEEL WAS SWOLLEN AS SHOWN BY MEANS OF 1000 SUCCESSIVE HEATINGS AND QUENCHINGS.

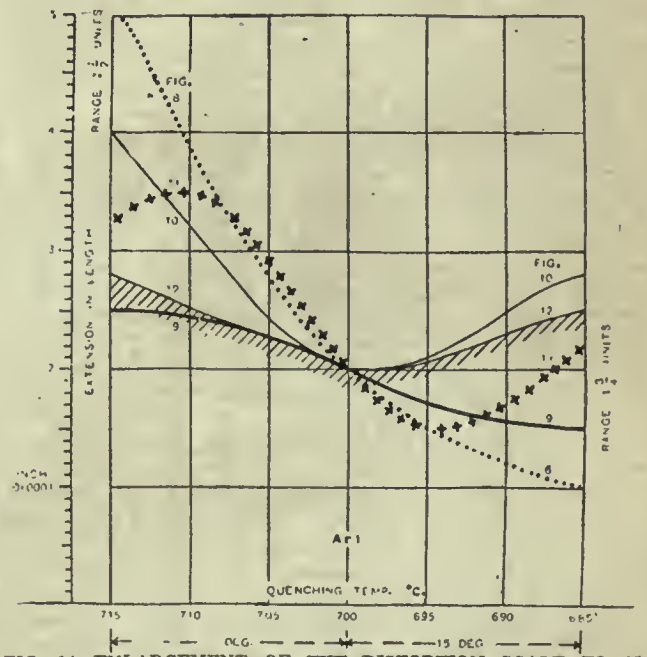

FIG. 14—ENLARGEMENT OF THE DISTORTION SCALE TO 15 DEGREES ABOVE OR BELOW AR1.

measurements of distortion on diameter were made, which always showed an increase of about 0.0001 to 0.0003 in., but the purposes of the research being the measurement of length distortion in screw gages, and time being pressing, diameter measurements were not proceeded with.

Before obtaining the pyrometers, which were not in use before April 5, some experiments were made on a color scale extending through

Bright red
Gray just appearing (due to freezing of the cyanide)
Full gray
Dull red
Black just appearing
Mid black
Full black

the specimen being held in a half light. The results pointed to a best temperature between dull red and black just appearing. Some experimenters have further perfected the color test, but the author considered the pyrometer method undoubtedly superior, and with his system of two furnaces could be practised by a somewhat unskilled operator.

Further experiments are needed on ring gages, which have laws of their own as regards diametric distortion, and the author had hoped to make experiments on other gage shapes.

It has not been exactly discovered what the first stages of distortion assume, for in the boy's experiments the diameters are all decreased, though it is certain they increased at first. It was believed that a barrel shape was first produced, coupled with end swelling, but careful test has shown a festoon shape on the rim, and it must be always remembered that nature insists on keeping the volume constant.

Instead, however, of waiting till all these facts could be obtained, it appeared wiser to make known the results that had already been acquired, in order that screw gages might be produced more easily and accurately by every manufacturer in a time of need.

The fact of the emulsive constitution of steel at Arl led the author to believe that gages quenched on this line would not be thoroughly hard. He was glad to say that, on the contrary, he had found them in every case to be glass hard. It must not be forgotten that the process of hardening by casing in cyanide produces a high-carbon steel at the surface, while the interior remains in the mild state, and this may have something to do with it.

The most important of the conclusions arrived at in this paper are:

(a) The second law of hardening is proved.

(b) A temperature of minimum distortion that can be relied upon is 700 deg. C. (1,292 deg. F.).

(c) No variation is allowable above 700 deg. C.

(d) An allowance of 10 deg. below 700 deg. C. is practically permissible.

THE PETROLEUM SITUATION IN THE CAUCASUS

The scarcity of the petroleum oils and the rising prices of the same in this country give a special interest to a report that has been made on the petroleum situation in the Caucasus by M. Aldebert as published in Le Geine Civil.

Communication with the oil regions of the Caucasus, which was becoming more and more difficult since 1914, was cut off entirely in 1917 because of Bolshevism and the Turco-German occupation. At the present time we are still very poorly informed on the subject. Widely different and contradictory reports are in circulation, and the report of M. Aldebert sets out to classify the situation as it existed on January 1, 1920.

Almost the whole of the Russian oil production comes from the Caucasus. In 1916 this amounted to about one-sixth of the total production of the world, and ranked Russia as next to the United States as a producer of mineral oil.

Although the Caucasus forms a continuous oil-bearing basin, for indications are found upon both the northern and southern slopes of the mountains, M. Aldebert divides the territory into three sections where the principal developments are concentrated:

1. The Maikopp section, which yields about 1.2 per cent. of the Russian output.
2. The Grosny section, which yields 17 per cent.
3. The Baku section, yielding 78 per cent.

In the Maikopp section, which is divided into three groups, there are 138 wells, of which only 38 are worked. These have a daily yield of about 67,000 gallons. The principal group at Maikopp is connected with the refineries at Ekaterinodar by an 8-inch pipe line about 87 miles long. The other two groups are connected by pipe lines to the tanks on the Ekaterinodar and Nova-Rossisk railway. The production of the Maikopp section rose from 503,000 gallons in 1908 to 47,140,000 gallons in 1912, but fell to 10,309,000 gallons in 1916, while in 1919 the output had again risen to 15,400,000 gallons.

These operations have suffered very little from the war, being situated in the centre of the provinces of Couban and Tereck, where the population is Cossack and, from the very outset of the revolution, have resisted the Bolshevik movement and have made up the nucleus of Denikine's army.

At Grosny the section is divided into two parts, that of the Old and New Rayon, located at a distance of about 9 and 3 miles, respectively, from the city. The operations at Old Rayon have not been destroyed, either by the revolution or the uprising of the populace, but at New Rayon the operations have been almost totally destroyed.

In November, 1917, seven flowing wells were fired and burned until February, 1919. Some of these wells had a yield of more than 283,000 gallons a day. An immense layer of lava produced by the burning oil covers the slopes of the hills to a depth of more than a foot. This lava consists of a petroleum coke and is actually used as a fuel under boilers. The wells which were not burned were destroyed with the axe and dynamite.

At New Rayon, out of 122 wells which existed before the revolution, only 5 are now being worked; 7 are being repaired, while the others are idle or have been abandoned.

The operations of the Grosny basin were begun in 1896, and grew continuously, except for a slight fluctuation during the first revolution of 1906, and reached a total yield, in 1917, of 550,300,000 gallons; but it would have reached 786,000,000 gallons had transportation facilities been sufficient.

In addition to tank cars there were 8-inch pipe lines leading from the district to the Caspian and Black Seas which, before the war, had a daily capacity of 10,310,000 gallons, while to-day, after repairing the pipe line destroyed in 1917 and the two pumping stations out of four, the capacity is only 471,000 gallons a day.

At Baku the production of the Akcheron peninsula, which was 258,000,000 gallons in 1882, steadily increased until it reached its maximum of 3,457,000,000 gallons in 1901. The revolution of 1905 cut the production of this section down to 2,106,000,000 gallons, but as matters became settled it rose to 2,467,000,000 gallons in 1916, although the scarcity of repair parts, machinery and material began to make itself felt in consequence of the war and the closing of the Dardanelles. The year 1918 brought in anarchy, and industry was completely paralyzed.

The year 1918, with a production of 630,000,000 gallons, saw the nationalization of the petroleum industry, followed by a Turkish occupation after several days of bombardment with its horrors and massacres. The economic disorganization is complete; there are now neither new operations nor exportations, and output is reduced to a minimum, so that we have to go back to 1889 to parallel it.

At the end of 1918 English and Russian troops occupied Baku anew. It had suffered from bombardment, but the operations were intact.

In 1919 a Tartar government was established, which later became the Republic of Azerbeidjan and was actually recognized by France. When order was established in August, 1919, the English evacuated Baku and, contrary to the forecasts, there were no massacres and no disorder.

But oil production was reduced to a minimum because there were almost no exportations, Astrakan being in the hands of the Bolsheviki, and Astrakan, before the war, handled about 75 per cent. of the Baku exportations.

In order to span this crisis the government advanced money to the operators in order to enable them to carry forward new operations, but as the tanks are full the situation is a difficult one. The ex-

(Continued on page 64)

WHAT OUR READERS THINK AND DO

DOUBLE FACING TOOL

By F. SCRIBER

To reduce the time required for facing discs which were held in a chuck in a lathe, the tool holder shown in Fig. 1 was used. The fundamental feature of this is that one tool (say for instance A) is set for rough facing, while tool B is set so it will face to the finished size. Having these two tools A and B set in the block C they are clamped securely thereto by the square headed screws shown. The necessary top and side clearances are ground on these tools, so they need not be set on an angle. The other units are provided to bring the tools successively into position for doing the facing, in other words the block complete with tools is mounted on a cross-slide of a lathe with tool A set for roughing size. The tool is then fed across the work in the usual manner thereby completing the roughing out. After this nut D is loosened by the operator, which allows block C to be lifted above tongue E by means of spring F. The block C is then turned by hand quarter way around, bringing tool B into position now occupied by tool A, and the finishing cut is taken across the work after tightening nut D, which compresses the spring and holds block C tight in position.

The various details which are used in this connection have been shown below

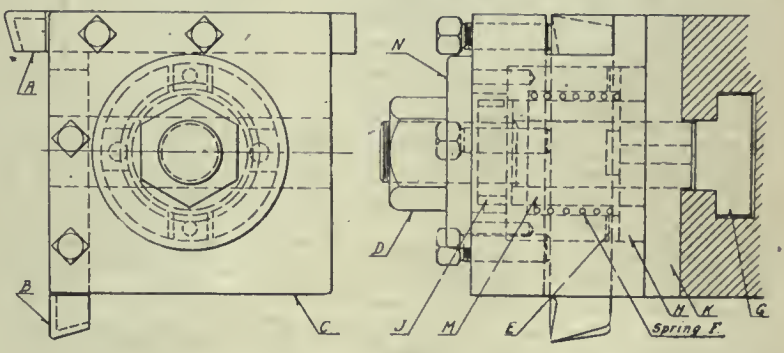

FIG. 1—THE ASSEMBLED TOOL READY FOR USE.

the assembly in Fig. 1 and in Fig. 2. These consist of a centre stud which is used in the centre of the block and holds the various members in place, a locating block H upon which the spring rests and above which the block is centralized by locating sleeve I and a clamping nut J used inside the swivel block C, the base block K is shown in Fig. 2, upper right-hand corner. Over this is slipped the swivel block C with locating sleeve I and block H between them.

When assembling this tool, locating block H is pinned to base K, tool-carrying block C has locating sleeve I pinned to it, clamping-nut J is screwed over centre stud G with a spacing collar M, which is not detailed between it and locating block H, thereby holding base K securely to the lathe cross-slide and locating it square by means of the tee section of the bolt in the cross-slide tee slot. Tool-carrying block C with locating sleeve I pinned to it is next put in position with spring in place, following which washer N is put over the centre stud. The nut is put in place and the arrangement is used as previously described. This type of block could also be arranged for turning by suitably locating the cutting tools.

It will be obvious from this description that loosening the hexagon nut D about one revolution allows the swivel block to lift the tool-carrying block clear of the tongue on the locating block thus allowing the swivel block to be turned the necessary amount.

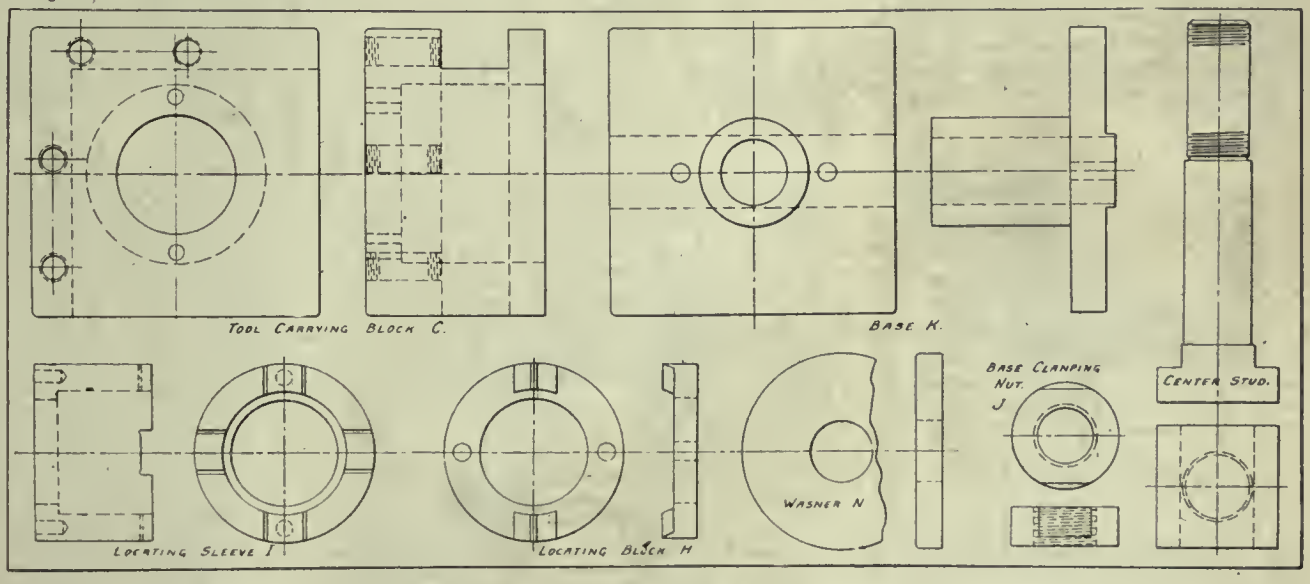

FIG. 2—ILLUSTRATING THE VARIOUS DETAILS OF THE TOOLS.

MACHINING ROD BRASSES

By Clyde D. Thorburn

For a considerable period we have been up against it for a quick method of machining the strap fit on main rod and side rod brasses. At one time our small crank planer worked about sixteen hours per day and could keep up with amount required, but with an ever-increasing demand for these brasses it was deemed necessary that we should endeavor to find some quicker means of production.

We used a long angle plate on planer and set up a row of brasses against it, but with the extra setting required we did not gain anything on cost of machining. In these days of high rates of pay it becomes more and more necessary for us to cut down cost of production, and as is well known, suitable jigs not only mean a reduced cost but uniformity of pieces and more per day.

Jigs as shown were designed specially for this purpose, and we expect to gain these favorable results. The jig is designed to suit a Bateman high-speed planer and to hold 10 brasses (5 on each side, two heads working). The body A is a double-angle plate, planed on base B to suit table of planer, and on both outside and inside faces. In the outside faces 5 holes 3 in. x 1 in. deep are bored at suitable centres (according to the size of our largest brasses) for cones C to fit into, and further holes tapped 1½ in. diam. to take studs D, which hold the step cones in position. Directly above these stud holes five more holes are drilled to take the sleeves E containing the locating pins F and springs G. Step cones are made of cast iron, and sizes of steps correspond with all our common classes of brasses.

Across the face of each cone four centre lines are cut to enable jobs to be set quickly and without the aid of surface gauge. In these cones four ¾ in. holes are drilled right on dead quarters to take end of locating pin. This is for brasses having four square sides. For brasses having one or more sides taper, other holes would have to be drilled in cones to give that correct taper.

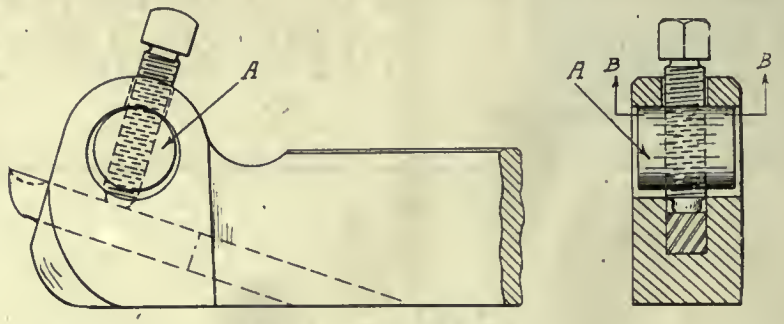
Brasses are faced on both sides and bored out to standard size. If bore is not required to be standard or probably left rough, these brasses would only be bored ¼ in. deep, or sufficient to fit on cone. Before brasses are bored they have previously been sweated together. In setting brasses on jigs, planer hand must see that joint of same is right on centre line marked across the face of cones. He applies the big washer H (which has a slot extending from centre hole to outside diameter to enable quick application and removal) and tightens up, only having one nut on each brass to tighten. An ordinary brass roughing tool will be used for planing between flanges, and a square nose-finishing tool to plane down inside of each flange. Probably a square nose tool would do the complete operations if the amount of stock is not too great. The first side of brass machined, all that is required is to slacken the nuts on inside of jig, pull back the locating pin and revolve cone until locating pin falls into next position. A small jack I is used (made of a nut and set-screw) under front end of brass to prevent a possible slipping of brass on cone. This jig practically eliminates the setting, previously a part of the operation that accounted for a lot of time.

During 1919, France, England and Sweden were the principal buyers of cash registers, which, together with parts, amounted to $4,375,526.

MODIFIED TOOL HOLDER

By Tyke

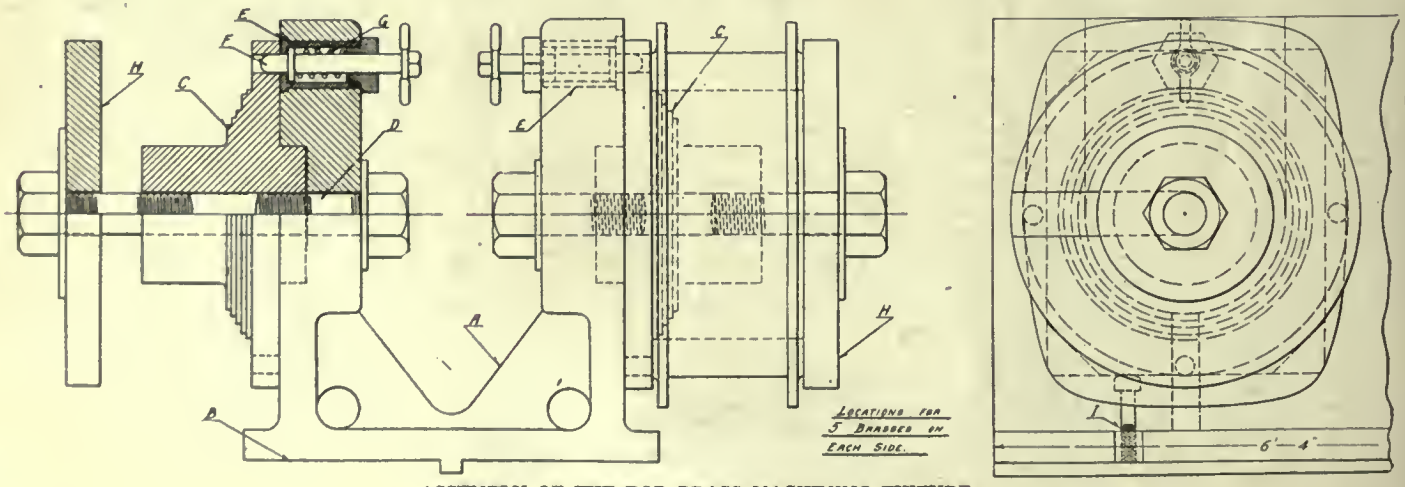
Time in a small shop is of vital importance, but no matter how careful one is small tools are very apt to get—well not exactly lost, but very badly misplaced. This is especially true when any device is made up of two or more loose pieces. These are liable to be dislodged by vibrations or shocks. Such an occurrence happened the other day and the part lost was the cam out of a tool holder.



DETAIL VIEW OF THE TOOL HOLDER.

Tool holders when desired are wanted at once, and mean lost money. The holder and wrench were located in their customary places, but the cam had vanished. After considerable time had been spent in the usual shop hunt for the lost parts, it was decided to improvise. When looking at the main body of the holder and seeing only a hole instead of the familiar cam it looked almost hopeless, but after a few minutes' cogitating a very simple, practical and efficient method was decided upon.

A piece of 3-4-in. cold rolled steel about 7-8-in. long was cut off, drilled and tapped for a standard 3-8 set screw. The upper portion of the tool holder was drilled 13-32-in. and the job was completed. The cold rolled piece "A" was placed in the hole and the set screw inserted and screwed home. It will be clearly seen that as soon as the set screw bore down on the tool bit the piece "A" rose in direction of arrows "B" until its progress was arrested by the upper part of the hole, after which the tool bit proper received the full pressure exerted by the set screw.



ASSEMBLY OF THE ROD BRASS MACHINING FIXTURE.

Would You Like to Receive One of These Scales FREE?

You can do so very easily, at the same time increase your knowledge and powers of perception.

The scale is 6 in. long and is made from finest quality steel. One side is marked in 32nds, the other side in 64ths. A table of decimal equivalents is also stamped on one side, and a table of tap drill sizes on the reverse side. This scale is well worth securing.

Rules of the Contest

The answers to this novel contest continue to pour in, and for the benefit of those who do not understand its value and scope let us explain. Every week we publish a list of puzzling queries similar to those below. It is up to the reader to read the query, turn to the advertising pages, and find the firms we refer to. These puzzling references are interesting to follow, and will quicken your powers of perception. It costs nothing, you get acquainted with the different lines, and have an opportunity to win a prize worth while.

The Lucky Prize Winner for Nov. 4th Issue List is GEORGE PILGRIM, Box 407, Dundas, Ont. He Had All Answers Correct.

INTERESTING FACTS TO BE FOUND IN THIS WEEK'S ADVERTISING SECTION

1. Something that wins friends even under adverse conditions.
2. A product that is shipped in four ways.
3. A machine that tells the cold blooded truth.
4. How to assure accuracy.
5. A machine that will produce two distinct classes of work at the same time.
6. An interesting operation economically performed.
7. How to save time, labor and money.
8. A product that is said to be breaking production records.
9. Something that can be cast quickly and at slight cost.
10. A product that can be made to meet individual requirements.
11. A book is often dull, but somewhere in this issue we read of another article that gets dull, and like the book, should be laid aside. What is it?
12. Something about a machine that when it is in place is as firm as the spindle itself.

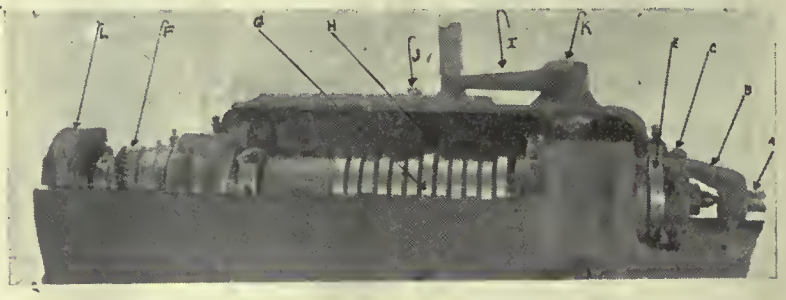
DEVELOPMENTS IN SHOP EQUIPMENT

CAM-GRINDING ATTACHMENT

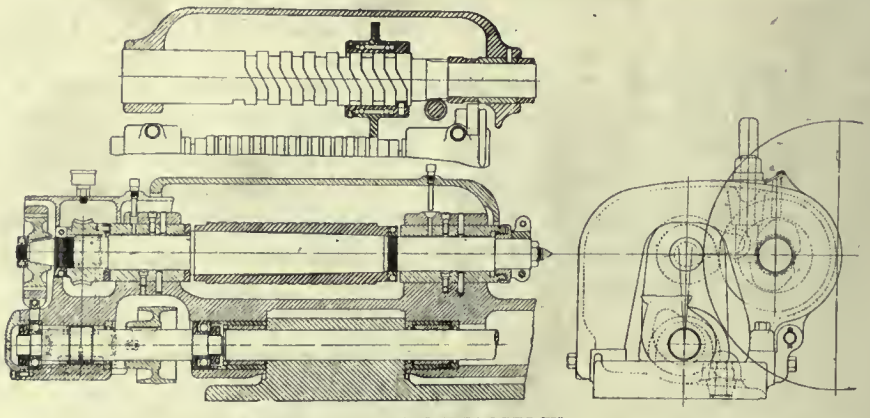
In designing cams of various shapes for automobile crankshafts, the tolerance has gradually been reduced so that grinding machines are called upon to produce many difficult shapes to meet the requirements of accuracy. In order to obtain a silent cam, clearances have been reduced and at the opening and closing points in some cases there is a slight rise in a number of degrees; for example, 0.005 in. in from 20 to 25 degrees. To provide for these requirements a new attachment for use in a cam-grinding machine has been developed by the Landis Tool Co., Waynesboro, Pa.

The accompanying photographs show the attachment mounted on the Landis 10-inch plain self-contained machine. The camshaft A is driven by dog B, which in turn is driven by driver C, mounted on spindle E and is adjustable to facilitate in setting camshaft in proper relation to master cam. On this spindle is worm wheel F, the spindle being worm driven throughout. On spindle E is master cam G, which is made from solid steel and mounted on spindle by means of taper and nut. In contact with the master cam is roller H, which is moved from cam to cam by means of lever I. The relative position of the roller is indicated by pointer J. By means of a cam on shaft K the roller and master are disengaged by a half turn of lever I and the roller shifted to the next cam by completing the turn. Thus, the roller and master cam are disengaged and roller shifted to proper position by a single movement. On spindle is also placed brake L, its object being to compensate for any lost motion, which would be reflected on cam as the pressure is reversed when passing over the nose.

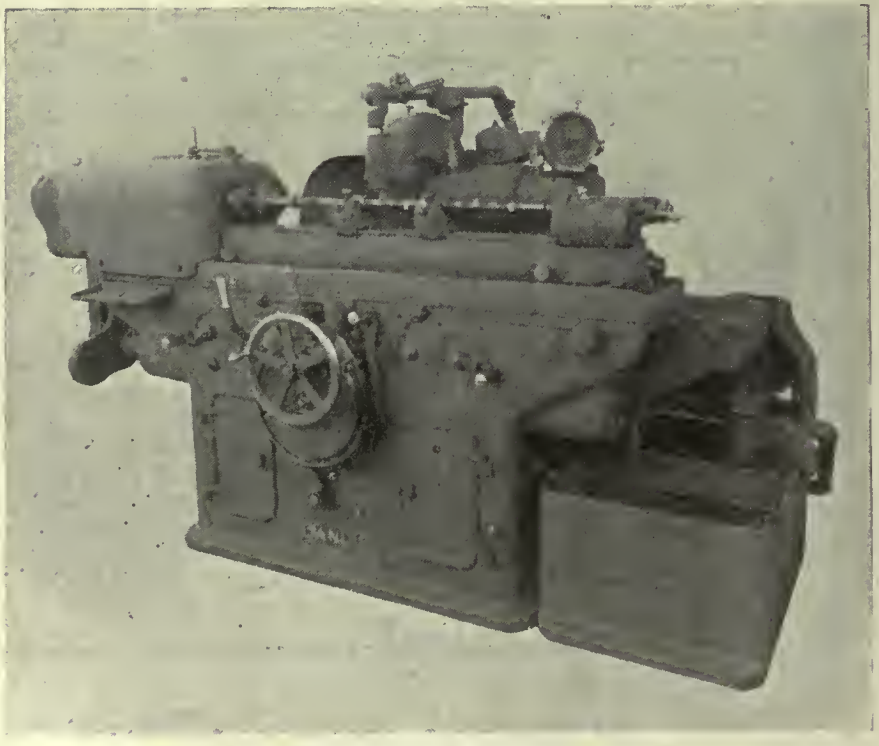
The outstanding features of the new underslung cam grinding attachment as explained by the manufacturer are as follows: The swing bracket is tubular in the cross section and is well supported directly under the master cam and work centres close to the machine bed. This construction balances the swinging bracket, eliminating all strain. The work being carried directly over the fulcrum centre reduces the vertical movement and grinding contact from changing over the periphery of the wheel, thus cutting down to a minimum the difference in contour of cams caused by the changing diameter of the grinding wheel. The



DETAIL VIEW OF THE CAM ATTACHMENT.



DETAIL OF THE HEADSTOCK.



GENERAL VIEW OF THE GRINDER.

master cam being mounted directly on the headstock spindle, substantially connected and in line with the work, eliminates lost motion and errors. The master cam is kept in contact with the master cam roller by means of compression springs, the tension being adjustable to suit different conditions.

It is pointed out that accurate work is secured when the grinding wheel is of a diameter equal to that of the roller used in contact with the model cam when generating the master. This condition is caused by the contact between the work and grinding wheel travelling above and below the wheel centre. The more the grinding contact varies from the wheel centre, the more pronounced the variation in the contour of the cams ground with different sized wheels. Due to the work being swung an equal distance from a point directly over the fulcrum centre, the movement of the work is practically in a horizontal plane, reducing to a minimum the travel of the grinding contact above and below the wheel centre.

GEARED HEAD TURRET LATHES

The Warner & Swasey Co., Cleveland, Ohio, have placed on the market what is known as their No. 4 and No. 6 geared head construction turret lathes. These lathes have a geared-head construction which is said to deliver four times the power transmitted by the ordinary geared friction head of the same size machine, and twice the power of the double friction back-geared type. Even with this increased power, less effort is required to move the controlling levers; consequently the machine is easier to operate.

The front view of the No. 6 turret lathe with a geared head is illustrated in Fig. 1. The first model of this type built has been thoroughly tested under every condition that might be encountered in service, and six machines of each size have been installed in outside shops for similar experimenting. The results obtained from all these machines have been very satisfactory.

Fig. 2 shows a view of the geared head with the cover removed, from which it will be seen that the steel gears are of a coarse pitch and have wide faces. The gears run in a bath of oil which also lubricates the bearings. Two sets of gears are mounted on the front shaft, while a third set and the reverse friction clutch are mounted on the back shaft. Twelve spindle speeds and a reverse rotation are obtained. Another advantage claimed for machines of the geared-head construction is their adaptability to the various types of motor drive. The head may be geared directly to the motor or driven from it by means of a chain or belt.

The No. 6 turret lathe can be equipped with the standard carriage used on Warner & Swasey turret lathes, one of which is shown on the machine illustrated, or with a heavy-duty carriage that is specially valuable when taking heavy cuts or performing heavy forming operations. A range of six power cross-feeds is provided on this heavy-duty carriage for facing, forming, and cutting off work at various speeds. The No. 4 turret lathe is equipped with a standard carriage. The maximum capacities of this turret lathe are as follows: Diameter of bar stock, 1½ inches; length turned, 10 inches; swing over bed, 16 inches; and swing over cross-slide, 7 inches. The maximum capacities of the No. 6 turret lathe are as follows: Diameter of bar stock, 2¼ inches; length turned, 12 inches; swing over bed, 20⅜ inches; and swing over cross-slide, 9¼ inches.

AUTOMATIC MILLING MACHINE

The Potter & Johnston Machine Co., Pawtuckett, R.I., have placed on the market what is known as their No. 1M automatic horizontal milling machine. This machine has been designed in response to a demand for a smaller automatic milling machine built upon similar lines to their present 2-M automatic milling machine.

In designing this machine, two tables have been used, making it a duplex milling machine, a feature which will prove valuable in a great many ways, this arrangement making it possible to handle two distinct classes of work upon the same machine without the operator moving away from the operating position. On the automatic milling machine the operator is loading up the fixture on one side of the table, while the cutter is milling work mounted on the other side, and with the exception of ten seconds required for indexing the table turret and advancing the table automatically to the cutting point there is no lost time, thereby insuring a greatly increased output. As soon as the operator has loaded the fixture on one table he performs a similar operation on the other table, keeping both sides of the machine loaded with work. There are no overhanging arms or projections to interfere with the operator while replacing work in the vise or fixture and all controlling levers are convenient to the operator. There is no waste of power as the machine is practically continuously milling.

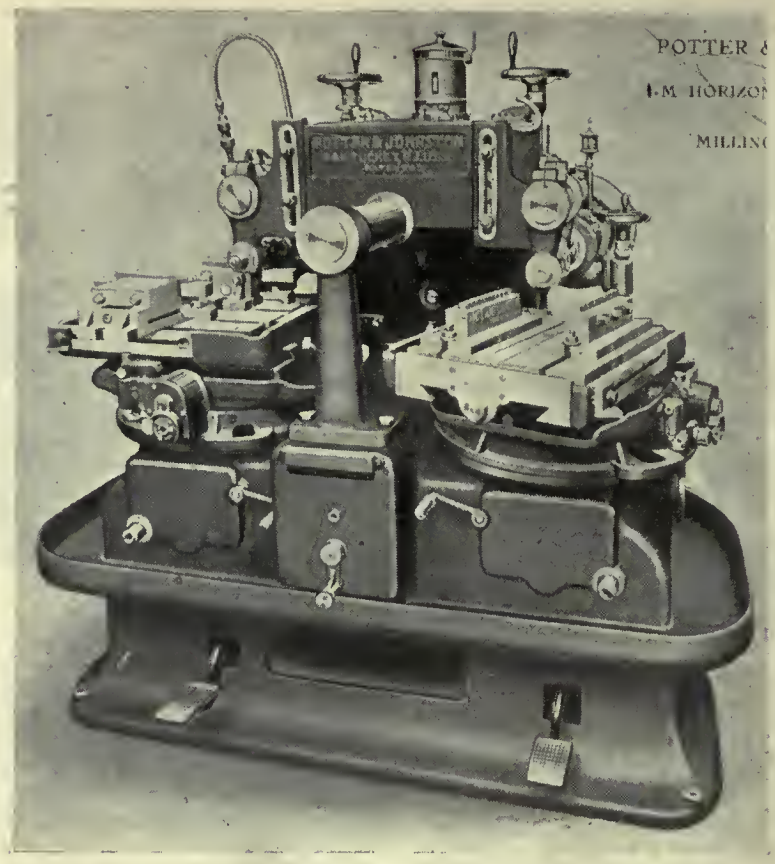
The table base carrying the work tables is at a fixed height, has walls of ample thickness, well braced, and runs to the floor, giving a rigid construction and solid foundation. In this base is the

mechanism for revolving the table turret and feeding.

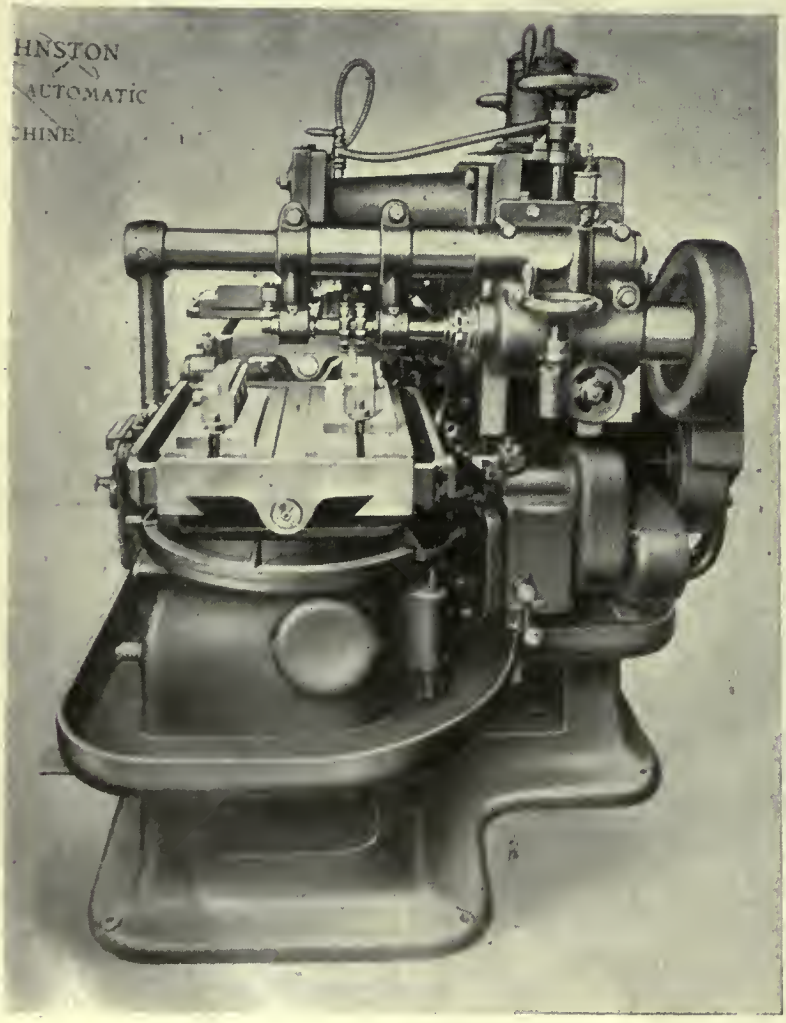
The tables are mounted upon circular saddles or turntables, and the rotation or indexing of these is of the turret principle. Each table has two tee slots, and a wall which runs entirely around the table serves the double purpose of providing a channel for lubricant as well as supporting the vises or fixtures, which are greater than the width of the table, the top of this wall being finished off level with the top of the table. One vise or fixture is carried on each side of the table.

The feeds for each table, which are independent of each other, are accomplished by trains of gears. Sixteen changes of feed are obtainable in practically geometric progression, ranging from 13-16 to 17¾ inches per minute. With each set of change gears two variations of feed are obtained by changing the hand lever at side of machine to either slow or fast position. The feeds for each table are also independent from the spindle speeds.

Provision is made for operating the tables by hand, also revolving the turret tables when setting up. Automatic stops are provided which are adjustable to suit the different working positions at which tables may be set. When indexing, the tables come to their working positions rapidly and automatically, thus avoiding



THIS VIEW SHOWS BOTH TABLES CLEARLY.



GENERAL VIEW OF THE MILLER.

any hand motion to bring the work up to the cutters. As soon as indexing is completed, the table feed is automatically thrown in. An independent, fast table feed is provided which is a time saver when straddle milling, groove milling, or space milling is being performed, as it brings the work clear of the cutters before the table revolving motion is thrown in.

The revolving and indexing is accomplished by foot pressure on lever at front of machine (each table having its own lever) and the revolving mechanism brings the table turret to the exact position before the lock bolt takes its seating. Ten seconds only are required to revolve and index the table turret, and this is the only period when the cutters are not cutting metal. The design permits of all automatic mechanism being operated by hand.

The spindles are made of crucible steel forging, ground, and running in bearings of phosphor bronze. Compensation of wear is provided in spindle bearings; the front spindle bearing is tapered and the rear spindle bearing straight. The spindle nose is clutched for driving an arbor; the arbor is held in place by a draw-back rod through the spindle, and the spindle is tapered at the front end to receive arbors. The spindle is carried on a vertical adjustable slide, which is in turn carried in a horizontal adjustable sleeve, which is responsible for the traverse of spindle. The adjustment for both spindles is independent. Graduated dials facilitate the settings.

The spindle drive is actuated by means

The Price of Machine Tools

THE automobile situation must give an effective answer to the idea that cut prices will bring about a worthwhile buying movement.

When the first cuts were announced, there was some buying in almost immediate response to the move, but, upon analysis, it was found to be almost entirely dealer trade.

When these orders were filled the movement was largely stopped, as there was no buying on the part of the ultimate consumer.

And that is where the business in cars stands to-day. The cut has apparently been made in vain.

Machine tool men will bear this out. Reductions have been made in some cases, but is there evidence that it has brought in a corresponding amount of new business?

The feeling at the National Machine Tool Builders' Association was against reduction, claiming that no good would result. Against that was the minority report, expressed at the Dealers' Convention, "Prices must be made lower on machine tools, for the buying expects it. I think that a general reduction is almost essential."

The trouble with all conventions is that they bring together men with the same mind, leaving aside for the time being the men to whom they look for the bread and butter of the business, viz., the buying public.

The buying public can be conveniently ignored at conventions, but they must be reckoned with when the dealers get out to put into actual operation the extra steam generated at conventions.

The dear general public may demand lower prices in machine tools, but the thing the dealers and makers would like to know is—would they come along and buy simply on the strength of a price reduction?

The Joy of Accomplishment

MR. J. H. BAIRD, founder of the Baird Machine Co., of Bridgeport, Conn., has died at the ripe old age of 93 years, and his passing will be regretted by lovers of machines and inventions.

Mr. Baird will not live as a great business man, although he was wise enough to surround himself with good business executives. He will be remembered and loved for his own words, "Well, I don't care if I did lose money, I made the dern thing work." That is the frame of mind that extracts pure, unadulterated pleasure out of accomplishment. He would take more out of gaining his point in mechanics than out of making a million in cash.

It was this feeling that made Mr. Baird the success he was as an inventive genius. Were he alive to-day he would probably object to the term "genius," but he would have to admit that at least it was the reward of patience. He made pins. He did away with the idea that "it takes ten men to make a pin." He made pins and made machines that put them in the papers—and after that he made another machine that made safety pins.

Many of his inventions bore out the fact that an inventor is often a poor business man. For instance, years ago Mr. Baird made a machine that fastened the hoops in hoop skirts. This he sold for $30, whereas the man who purchased it made a resale for $50,000, which was almost a fabulous sum in those days.

And there is nothing on record to show the regret of the inventor. His name will live as the inventor of that machine, whereas the man who made the $50,000 out of selling it has been forgotten long ago.

The inventor put something real and lasting into the world—the man who made himself rich over a short handling did not.

Mr. Baird was a relic of the old school, where accomplishment was counted greater than reward, where, in fact, accomplishment was its own reward.

And after all is said and done, it's a pretty fair record to leave in these money-mad days:—"Well, I don't care if I did lose money—I made the dern thing work."

A profit-sharing scheme is a popular thing when there are profits.. A plan that will hold interest in the lean days is more to the point.

German engineers are working to secure a substitute for coal, the idea being to draw electricity direct from the atmosphere. The idea is well within the range of possibility that in years to come our present expensive power plants will be scrapped, and mechanics and engineers of years to come will regard them as we do the tread mills of past generations.

What the Business Papers Say

Paying on Basis of Results

Engineering, London.—"When we turn to the question of the acceptance of payment by results by the unions as a whole we are again obviously at once confronted with difficulties. In this case, however, we think the opposition would come more from certain unions officially than from the individual work people. This should make the matter more easy to deal with. Various systems of payment by results are, of course, in operation in many trades, and in general are certainly favored by the people who work under them. In other trades the system is forbidden, but we know of more than one case in which such a system is being worked to in certain shops with the full concurrence, and even at the desire, of the work-people in defiance of union rules. A general acceptance of payment by results is not going to be granted off-hand, but the bringing about of such an acceptance is a sufficient possibility to make the matter well worth bringing forward in a definite way."

Where Prices Really Stand

British Trade Review.—Common talk on this question of price-reductions has been often misleading. To a large extent recent downward movements are due to abstinence from buying, and it is quite clear that this holding off on the part of purchasers cannot go on indefinitely. Since present quotations in some cases represent the minimum of profit, or even a loss, to the seller, it is clear that the position is to some extent artificial, and it would seem to follow that when buying is resumed prices will harden in the classes referred to. The world is still hungry for goods, and when activity is resumed in the markets it is more than probable that buying will be conducted on a large scale. Under the circumstances the question arises whether the present would not be a suitable time for buyers to consider the advisability of recommencing operations.

MARKET DEVELOPMENTS

The Markets Afford an Interesting Study

Many Sides Are Shown This Week—U.S. Steel Prices May Come Down Below Corporation Levels—New York the Scene of Gatherings of Dealers and Makers, But No Price Announcement Results.

THE conventions of both makers and dealers in machine tools have come and gone, but so far they have not been followed by any announcement regarding reduced selling prices. At both of these meetings the point was made a good many times that present costs are very high and not out of line with the selling prices. Cancellations were also spoken of, and it was found that conditions in United States in this particular are probably worse than in the Canadian field, as the number of cancellations here has been comparatively small in all lines of machine tools.

Iron and steel warehouses are doing a fair trade, and prices remain about the same. This week sheets dropped back a little, as there are quite a number of re-sales in the market, coming from manufacturers who find that they are rather heavily stocked with high-cost material and prefer to get rid of some with the idea of stocking up later on at a better figure. There is a good demand for most lines of sheets though, and the surplus stock is not going to influence the market very much one way or the other.

Boiler tubes are in demand, many of the boats being tied up now ready for the season's repairs.

The automobile shops are not in any better condition than they have been for some time back. The reductions announced in the price of cars were taken up by dealers who placed orders for next season. When these were taken care of the buying ceased, and orders are badly needed in nearly every car shop in the country.

The scrap metal market can stand almost any phrase that one cares to apply to it this week, and the more strenuous the phrase the more pleasing to the dealers. Some of the yards must be having a hard time in making ends meet with the amount of trade that is in sight, and there is nothing in particular that would encourage the belief that things are going to get better. The steel mills are not buying, neither are the foundries, while offerings for non-ferrous metals do not exist.

MATERIAL COMES VERY QUICKLY FROM THE STEEL MILLS NOW

Special to CANADIAN MACHINERY.

MONTREAL, Que., Nov. 25.—The steel market today reflects the conditions that exist in almost every phase of industrial life. Doubtless, the seasonable quietness is responsible for much of the dullness, but other factors are influencing the apparent depression that is becoming more pronounced every day. The tendency to lower prices on steel commodities is more or less marked in every direction, but nothing drastic has yet been done in the price-cutting movement. Operations at the mills are becoming more restricted and production is fast becoming a problem. It is easy to get the output but the mills are reluctant to produce steel far beyond the immediate requirements of the trade, and these demands are below normal, and at the same time very irregular.

The cry of delayed delivery on many classes of steel is now a thing of the past, and if heard at all, is a feature of transportation rather than production. This might be exemplified in the statement made here by a dealer. "Just recently," he remarked, "we mailed an order to our American mill for some material that had to be rolled to special dimensions. At the beginning of the following week we were requested, by the consumer, to make some slight changes in the sizes previously stated. We immediately wired to the mill, only to be advised that the material had been rolled and was ready for shipment. This, while being a specific case, is nevertheless true of the general market." In commenting on the decline of price quotations the dealers could not say how far this would extend but could not see where any great reduction could be made in the face of existing cost of labor and materials. Raw materials, of course, were becoming more reasonable in price, but production costs per ton showed little decrease. There is, however, a feeling that general adjustment of wages may follow the movement in this direction by individual firms. Canadian mills are showing the trend of the times, as reports indicate a decline in the volume of business on the books. One local dealer stated that the general quotation in Pittsburgh for tank plates was $3, and that even lower prices had been reported. The price here, from warehouse, was on the base of $6 for ¼-inch and up, and $6.50 for 3-16 inch plates. Demand in this regard shows a marked falling off. While some mention has been made of an easier situation in boiler tubes, the needs of the trade for this commodity is still ample to maintain the present strength of the prices quoted. The easier market in sheets shows the effect of the inactivity in the auto industry, and the prices reflect the volume of the supply over that of the demand. Quotations here are on a basis of $9.25 for No. 28 gauge black and $7.75 for blue annealed No. 10.

Inquiries Still Come In

"It is only the man who is definitely persuaded that he needs a tool who is in the market at the present time." This statement seems to reflect the condition generally prevailing in machine tool circles. Some dealers report a good week, but the sales in the aggregate are below normal. While admitting a falling off in heavy machine tools sales, nearly every dealer agrees that the trade is in need of equipment and that the slackness now evident is more than a seasonable one. The consuming trade in ma-

chine tools is no different than in other lines where people are influenced by the lowering trend of prices. When the market was in the ascendant the cry of replacement values held the attention of all, particularly of the consumer, and this is one factor of present trading that is responsible for much of the business let-up. One is encouraged, however, at the optimistic tone of some dealers' remarks, and the turn of the year is expected to open the way for a renewal of more active trading. In speaking to Canadian Machinery one dealer stated that during the past month he had received many inquiries for different lines of equipment, and while realizing that the great majority of these were nothing but price feelers, he felt it his duty to answer such inquiries, but in most cases nothing further developed.

Coppers and Tin Down

Metals, like other commodities, are absorbing some of the dullness that is prevalent throughout the country. Sales are quieter than for many months, partly due to seasonable decline and partly to the general retrenching policy of many lines of industry. Few deny the normal requirements of the trade, but until the country as a whole becomes a free buyer the metal situation will experience a quiet period. Coppers have again declined locally to the extent of 1 cent per pound. Lake is quoted at 20 cents, electrolytic at 19½ cents and castings at 19 cents per pound. Tin is affected by the decline on the English market and shows a drop of 4 cents per pound. The quotation here is 48 cents per pound.

Dullness Very Pronounced

"Still in the same position," remarked a dealer in old materials. "Waiting for something to turn up and convert the dullness into cash. There is practically no market and prices are little guide to the situation. Quotations are necessary, I suppose, and those given are as good as any other." When asked as to what prices would actually be paid, the dealer stated that it would all depend on the nature of the sale, and with sales of a negative character, the prices were of little consequence. The scrap movement here is very light and irregular.

NOT MUCH CHANGE IN THIS MARKET

Prices For the Most Part Are Holding Firm—Scrap Market Remains Inactive

TORONTO.—There are several lines of business in this district that could, just now, report trading almost the same from week to week. There are a few firms with high spots, there are a few with the very low spots, while most of them are in between. For the most part dealers recognize that they are going through a period where their business acumen is going to be taxed, but they have looked forward to this period coming for a long time back. Generally they are prepared to stand it, although in some cases credit and finance are receiving a great deal more attention than ever before.

The local machine-tool dealers do not see much in the proceedings of the National Machine Tool Builders' Association to justify the belief that there will be a cut in the prices soon. One of the salesmen from a large American firm, who spent some time in the district this week, stated that their price reduction had been made several weeks ago and they were selling now about 50 per cent. of their capacity. He was certain that, as far as his company was concerned, it would not be possible to make any more price reductions for many months to come.

The matter of price is also referred to at some length in another section of the markets, in reports from the convention at New York where these matters were freely discussed.

There are a number of inquiries coming into the market here, but the majority of them are for single machines, and many of these inquiries are not yet turned into real sales. Machines on order are coming in rapidly as a general thing, and the delivery schedules are getting pretty well worked out.

Small Tools Market

There is a real honest-to-goodness

selling going on in the small tool market. There are no large orders. The purchasing agents in this district are getting so used to seeing a number of the salesmen from the small tool houses or branches that they must be at the point where they can call most of them by their first name.

The National Railways are inquiring for quotations on an assortment of high-speed drills, but the business has not been placed yet. The prices, recently revised, are standing and are likely to for some time.

The Steel Market

There is still a fair amount of business in the steel market. In some cases there are lines that are moving well. There has been a marking down in the warehouse prices of black sheets and of blue annealed. The base price of 28's is now given as $9.50, and blue annealed at $8.50; galvanized 28 are still $12, and 10¾ are $12.40, although the galvanized prices are weak at this point, and a reduction is quite possible.

There is considerable reselling going on in sheets now. Manufacturers find they have lots on hand that are not needed just now, and they figure it would be good business to clear out their high-priced stock if they have the chance to do it. Against this there is the fact of a good demand for sheets, and the chances are that this surplus stock will be taken up shortly, and when this is done the market will have to face the ordinary conditions. It is possible to secure sheets at present on fairly short notice. For the most part the available stock is from the independent mills and fairly high in price. Corporation deliveries are expected by several of the dealers as they have been on the books for as long as twelve months. In view of the fact that they are likely to be getting this material they are not booking with the independents.

Tubes are in fairly good assortments in several of the local warehouses, and they are moving out well. The demand at this time of the year is from lake boats that are now tied up for the season and are undergoing necessary repairs. This makes a call for the larger sizes, 3½ and 4 inch, while the demand for tubes for industrial plants has not fallen off to any degree, as might be expected owing to the lateness of the season.

Bar iron is selling in fair quantities. This is hardly the season when one looks for a big movement in this.

Structural men figure that there is a lot of tonnage ahead of them in connection with a number of the larger buildings that are planned for this city and the surrounding district.

Pig iron prices vary according to tonnage taken and other terms of contract. A man who knows the situation pretty well sized up the situation this week as follows: No. 1 foundry iron, of 2.50 to 2.75 per cent. silicon is selling around $59 delivered in Toronto now, while No. 2 iron or 1.75 to 2.25 per cent. silicon would be about a $1 a ton under that figure.

Several U. S. brokers who have quite ample tonnages at their disposal have been going through Canada offering attractive figures on resale iron. Apart from brokers there are a couple of U.S. firms making a special effort to break into the Canadian market. Of course there is the duty of $2.75 per ton, exchange at current rates, which are a little higher than usual just now, and the carrying charges.

There is very little pig iron being purchased by the Canadian trade at the minute. A number of inquiries that come into the market are for purposes of estimating on contemplated work, and for the purpose of comparison.

A well-known maker of iron stated to Canadian Machinery that Canadian furnace costs were as high to-day as they were several months ago, and there were not many indications of reductions being in sight. However, he admitted that if it were found necessary there might be a readjustment in their selling schedule, although he still held that the law of costs and selling price did not warrant such a move.

The scrap market has been referred to as dull, dead, inactive, stagnant and everything else that gives the idea of no business being done.

Well, one might take any one of these new phrases now and apply it with perfect safety to the scrap metal trade. The export market is not lending any strength to the situation, as the outside markets are apparently facing much the same situation as the markets here. The steel consumers, if they are in the market, are offering prices that the dealers would not consider. Neither are the foundries doing anything better, nor has wrought iron scrap been asked for. Buyers of non-ferrous have not done much better in the way of taking anything out of the scrap heap. Small lots have been wanted, otherwise there is no movement. Some of the dealers are of the opinion that the list, quoted elsewhere, which is low enough, should be regarded as purely nominal, and it may be battered down even more, although no dealer had the heart this week to knock any of the figures down lower.

POINTS IN WEEK'S MARKETING NOTES

Pittsburgh says that production of steel is decreasing rapidly and that many of the independent mills are now not operating at 60 per cent. of their capacity.

—

It is rumored that the decrease in prices of steel, finished and semi-finished, may go below the Steel Corporation schedule.

—

Merchant blast furnaces have in many cases gone out of business. For a good many months users have been buying in very small quantities, and it has caused no surprise to find that some of the stacks are out of orders.

—

Machine tool dealers do not find much in the reports of the National Tool Builders' Association to cause them to believe that there will be a reduction in prices.

—

The National Railways are inquiring about high-speed drills, but so far no business has been placed.

—

There is a fair amount of business in the steel warehouses, especially in sheets and boiler tubes, the latter being called for at this time of year by boats that are now laid off for season's repairs.

—

Blast furnace men in Canada report that purchases of pig iron are being made in very small quantities.

—

The scrap metal market shows no signs of improvement in any line. Steel mills are not taking on anything at present and the foundries are not doing much better. Even the present very low price in scrap metal may have to give way to still lower levels before business is done on a larger scale.

BIG STEEL PLANT SHUTS OFF QUICK

In Response to Demands That Claims of Railroad Men Be Met At Once

Sydney.—When 125 railroad employees of the Dominion Steel Corporation served an ultimatum on the management demanding a settlement of their wage differences before five o'clock the same day the company replied by closing down the various mills at noon and ordering the banking of the blast furnaces. This action automatically threw 4,000 men out of employment, pending the settlement of the dispute with the railroaders. It is estimated that it will require at least a week to get the furnaces in operation again, and it is believed that the big plant will be tied up for that period at least. The company, in the meantime, it is understood, is making application to Ottawa for redress under the provisions of the Industrial Disputes Act. It has been stated that lack of orders has been threatening the operations of steel plants for some weeks past. For the past two years the railroaders employed within the steel plant have been contending for the scale awarded all other railroaders in Canada following the McAdoo award in the United States.

THE WORLD CALLS

NEVER BEFORE, AS NOW, HAS THE WHOLE WORLD CALLED

"PRODUCTION"

Are you doing any Screw Thread Cutting?
How are you doing it?
Do you know that Geometric Thread Cutting Tools have effected an enormous saving of time and costs in many thousand shops?
The first step is to investigate. Tell us the job you have to do, and hear what we can do for you.

THE FINAL SHIPMENT OF THE DAY---*THE FREIGHT SHIPMENT*

Express -- Parcel Post -- Auto Truck -- Freight

These are the four channels by which Geometric Screw Thread Cutting Tools and Machines are shipped.
There is no place where more business is done to the square foot than in our Shipping Department, because of the demand for Production Tools—Automatic Die Heads and Collapsing Taps—everything for more and better screw threads.
Make Screw Thread Cutting the Most Satisfactory Operation in Your Shop.

PRICES NOT LIKELY TO STOP AT STEEL CORPORATION LIMIT

Special to CANADIAN MACHINERY.

PITTSBURGH. November 24.—The pig iron and steel markets continue stagnant as regards new buying, while there is a further decline in specifications against contracts and a fresh wave of cancellations and postponements. Production, accordingly, is decreasing, and at a more rapid rate than formerly.

There is, in fact, a very sudden ending to the spell of steel scarcity, with heavy pressure upon mills for deliveries. It is by no means remarkable that the change should be sudden, the remarkable thing being that the pressure continued so long after various other industries had become quiet. The end of the period of feverish activity and the decline in inflation was foreseen long ago, even early in the year, when not a few observers were predicting a panic by August, and the Federal Reserve Board undertook to bring about a gradual deflation so as to prevent a smash. The steel industry maintained its activity longer than might have been expected, and naturally when the end came it came suddenly.

Prospective Prices

In the past two or three weeks the opinion has been spreading rapidly that before this readjustment in the iron and steel industry is completed there will have been declines in the Steel Corporation prices. Until recently, the common, almost universal, prediction was that the steel market would find its level, in the readjustment, by the independent prices dropping to the Steel Corporation level and staying there, the whole market being thus equalized and stabilized, with a fresh buying movement beginning. Many observers predicted that the operation would be completed by March or April. It is strange that the prediction gained such popularity, for it was essentially an unsound one. There was a time when, if the independents had voluntarily reduced their prices to the Steel Corporation or Industrial Board level, buyers would have had confidence in the prices thus made, but the opportunity is past. The order books of some independents are almost exhausted, yet they continue to quote their higher prices. Buyers see that the law of supply and demand is being disregarded by producers and are indisposed to have confidence in any prices quoted. When independents reduce their prices it will be only because they are forced to do so and when the Steel Corporation level is reached the independents naturally will not stop there, as there is no business waiting to be placed at that particular level.

The common prediction now, therefore, is that the independents will eventually go below the Steel Corporation prices. It is seen that the readjustment in business and financial conditions generally, in the direction of prewar prices, is going to go farther than was expected a few months ago would be the case. Production costs, therefore, will come down, and with a decline in costs selling prices for steel below the present Steel Corporation prices are to be expected.

Chairman Gary of the Steel Corporation late last week made a carefully worded public statement. The substance was that the corporation has had good grounds for advancing its prices above the Industrial Board schedule of March 21, 1919, for several reasons, including in particular the wage advances and the freight rate advances, but has refrained from doing so, and that it has been decided to continue present prices "unless and until it becomes necessary and proper to make changes to meet altered conditions." The iron and steel trade has experienced no difficulty in concluding that the qualification means that prices eventually will probably be reduced. As prices have not been advanced when costs increased, and costs are certain to decrease rather than increase in future, no other conclusion is logical. It is inferred that the corporation will have little disposition to reduce its prices in the near future on account of such shading of its prices as the independents will probably be indulging in within a short time, say within two months at the most. The corporation will then still be moderately well supplied with orders while the independents will have practically nothing left, and the corporation would hardly dispute the right of the independents to get some business, even though the independents have made such large profits of late that they could afford to be idle a half year or longer and still have greater profits in the aggregate than the Steel Corporation.

Production

Many of the independents, representing perhaps half the total independent capacity, are operating at 60 per cent. or less, this representing a sudden decrease. One large independent has been making scarcely any steel at all, while operating its finishing departments in a moderate way, working up accumulations of semi-finished steel. Very few independents are operating within 90 per cent. of their rate in August or September. The Steel Corporation's operations are well maintained, and with a possible exception here and there the corporation plants are producing larger tonnages than at any time since last March. However, it looks as though even the corporation would have to decrease operations soon at some of its plants, though probably only to a small extent.

As to the merchant blast furnaces, they have almost run out of business, and this is only what was to be expected, since for more than six months consumers have been buying very sparingly, only for early deliveries and then in as small tonnages as possible There is no demand in the market now, irrespective of price, and as furnaces would not think of piling iron when costs are on the eve of a great readjustment the only course is to blow out as soon as orders run out. While a furnace will not make up stocks for future sale, it will before blowing out produce enough iron to take care of deliveries that its customers are certain to take in the near future.

Iron and Coke Prices

Since last report market quotations on pig iron are down $2 a ton as to Bessemer and $1 on both foundry and basic. The declines occurred on extremely limited transactions, and the next business that develops will in all probability see further declines. The market just now is quotable at $40 for Bessemer, $39 for foundry and $37.50 for basic, f. o. b. valley furnaces, freight to Pittsburgh being $1.96.

Before buyers of pig iron and steel products take hold again with any freedom prices will be much lower, and the buyer will have much to say as to price. Profits will have to be telescoped. The pig iron buyer will not take hold in pig iron on the basis that the furnaceman is making no profit if he is paying a big profit to the coke maker. The coke maker must do his share. Thus far the coke maker has not seen the light. Connellsville furnace coke for spot shipment is $8 to $8.50, when $5 would afford a very good profit. As to Lake Superior iron ore, prices for which for the 1921 season will hardly be set before April or May of next year, little if any reduction is to be expected, as ore prices have been moderate right along. There may be a slight concession by the ore producers just to show their willingness to co-operate, and if there is any decline in the lake rate, which in the past season was $1.20, including the unloading charge at Lake Erie docks, that will be handed on to the ore buyer.

Street Railway Steel.—A number of conferences have been taking place during the past week between Toronto civic representatives and engineers and officials of the United States Steel Corporation. The whole matter rests with the proposed changes and extensions to the street railway system in Toronto, to be undertaken after the city takes over the road. The city is anxious to secure information as to the best way to make the change in track and possibly gauge, and at the same time keep the service in operation, and the experience of the U. S. Steel Corporation engineers was desired in this connection.

GRATON & KNIGHT

Announces

SWEEPING PRICE REDUCTIONS

The Result of Months of Concentrated Effort

FOR several decades the Graton & Knight Manufacturing Company has been the leader in the leather belting industry, taking the initiative in every important change. In keeping with this position, we announce a general price reduction on all grades of leather belting.

Only by taking advantage of every economy in manufacturing and marketing made possible by the tremendous volume of our business are we now able to offer to the public this substantial reduction in price and still maintain our high standard of quality.

This reduction became effective November 18, 1920.

The manager at our home office, 356 Franklin St., Worcester, or any of our branches, will give particulars upon request.

Making Fine Tools

An Interesting Operation, Economically Performed by Means of a DUMORE Grinder

This photograph — taken at the City Engineering Company's (Dayton, Ohio) plant shows a Dumore Grinder finishing the main shank and head of a special draw-in collet. There were 500 put through in this special lot and the time for the operation shown averaged 8 minutes per piece.

The second operation; grinding the internal face of the collet nut, was also performed by this convenient precision tool.

Dumore Grinders are popular here as in every plant where fine tools are made. Their accuracy makes them useful for the finest finishing work; their simplicity and convenience make them practical for many difficult, almost inaccessible jobs.

Dumore Grinders transform any lathe into a precision grinder; they make fine finishing possible in every machine shop.

May we tell you more about them?

DUMORE HIGH SPEED GRINDERS

Dealers Talk of Prices and Cancellations

Meeting Held in New York, Where These Matters Were Much Discussed—One Dealer Alone Speaks in Favor of a Reduction—How They Have Come Out on Cancellations.

REPORTS of the National Supply and Machinery Dealers' Association convention indicate that price recession and cancellations formed the chief topics of discussion, and that in the case of prices the sentiment was not at all favorable to urging for reductions. The opposite view to this was expressed by a Milwaukee dealer, who stated: "Prices must be made lower on machine tools, for the buying public expects it. I think that a general reduction is almost essential."

J. D. Doan, of the American Tool Works, Cincinnati, a manufacturer, who had at one time been a dealer, gave reasons which he said prevented a general reduction in the price of machine tools. He claimed that the wages of tool builders' labor had not been inflated as in the case of a certain stove manufacturer, whose molders had been getting from $15 to $30 a day. Therefore, wages could not be reduced. It costs about $40 a ton to make pig iron, he said, and iron is selling at that price now. So iron cannot be reduced. Moreover, thirty furnaces blew out in October, curtailing production. Neither is there great hope for a reduction of steel.

"There must be an honest-to-goodness reason for reduction of machine tools before any can take place," he continued. "I have had several instances called to my attention where business has not been placed because of the expectation of lower prices. A list would be issued; some dealer would quote a reduction on one tool, then the entire list would be held up, the purchasing agent expecting a general reduction. Our duty as an association is to stabilize confidence on the part of the buyers. One can't compare the machine tool industry with a more speculative one like the dry goods trade.

"If the cast iron entering one of our 18-in. lathes should be reduced 25 per cent., we could reduce the price of our finished machine not more than 3 per cent."

W. A. Viall, Brown & Sharpe Mfg. Co., Providence, R.I., agreed with the majority that prices could not be reduced at this time. He said that to-day there are no heavy stocks in the hands of the manufacturers. Their policy will be a receding one, tapering off production and placing in stock a few representative sizes. Nobody will take steps to increase plant capacities. Dealers can look forward to a period of quiet. The speaker had talked with several machinery men, some of whom placed the expected revival in April, others in July,

Probable Date of Revival

In the discussions, some named February as the month when the revival of business would set in. No one present admitted that he would be willing to reduce prices in order to liquidate stocks of tools on hand. In the matter of cancellations, all agreed that no two requests for cancellation could be handled exactly the same. The particular circumstances of the contract and the date of delivery of the tool would enter into the question. It was generally agreed that where delivery of machinery is delayed long after the specified time, the buyer may have legitimate reason for canceling. Many dealers had received such letters as this from buyers: "If you ship the tool, we shall be unable to pay for it."

One dealer narrated how the clause in his contract, stating: "No cancellations allowed without our consent," had been altered in recent contracts by striking out the last three words. A dealer suggested that buyers canceling be required to pay a certain percentage of the cost of the tool for the privilege, thus to compensate the dealer for his costs in making the sale.

TARIFFS DISCUSSED BY IRON AND STEEL MEN AT MONTREAL

Various phases of the iron and steel industry were brought out at the session of the tariff commission in Montreal. Some extracts follow:

W. W. Butler, on behalf of the iron and steel interests, upheld the need for a tariff to protect these industries. Steel and iron imports, he said, amounted for last year to $189,897,602, or 18 per cent. of the total imports. The bulk of pulp and paper machinery was imported, although the Canadian industry was now in a position to supply this material.

The Canadian industry was doubly hampered by having to import much of its raw material, and by the competition of a highly organized, well protected iron and steel industry in the United States.

The lead Great Britain once had in this industry had steadily decreased from the time free trade gave the protected German and Belgian iron and steel works an advantage in competition.

Adverse Exchange Rate

The purchase in the United States of goods which could be manufactured in Canada kept the exchange rate in an adverse position and unnecessarily increased the cost to Canadian consumers of other goods which are not manufactured here. At best the home market was none too large, and a long free list gave American companies an advantage in the Canadian market in many lines.

An enquiry by Sir Henry elicited the information that only the Algoma Mills were rolling structural steel, and they had just started. Apart from this, only small structural parts were made in Canada. Some lines which had been commenced lately by Canadian mills had had to be abandoned on account of United States competition. The American firms preferred their home market in time of shortage, and dumped their excess on the Canadian market in slack periods. The anti-dumping law, although good in principle, was not an absolute protection against dumping.

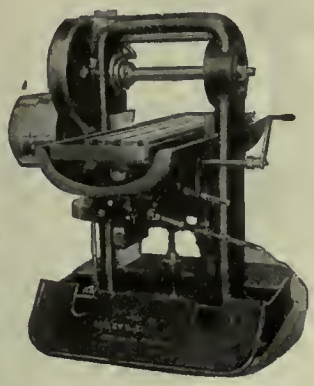
T. B. Howard, president of the Phoenix Iron Works, stated that the output of his industry had gone down very seriously since the war. This was an essential Canadian industry, and worthy of protection.

Sir Henry suggested that part of the Canadian structural people's troubles resulted from the fact that they had to buy structural steel from firms who later competed with them structurally. Would it not be to their advantage to have structural steel manufactured here?

Mr. Howard agreed that it would. If the Algoma company developed in this direction it would be of great use to them.

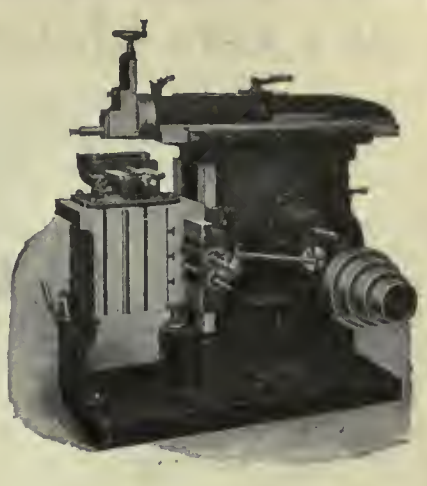
The industry had attracted to itself $26,000,000, represented by expensively equipped shops. It provided a field of employment for many university graduates and scientifically trained men. Its mechanics were highly skilled and big wages were paid to its construction workers. The United States firms had the advantage in climatic conditions and larger contracts and could therefore easily invade the Canadian market.

James Percy McNaughton, who for nearly twenty years has been general sales agent for the Dominion Iron and Steel Company at Montreal, passed away this week after a brief illness. Before associating himself with the steel company, Mr. McNaughton was in partnership in a brokerage business under the firm name of Lamplough and McNaughton. He was born in Ottawa 53 years ago. He leaves a widow and two sons.



GARLOCK-WALKER'S

LIST OF METAL WORKING MACHINERY IN DUFFERIN STREET WAREHOUSE, TORONTO



Lathes—Engine

All sizes of Engine Lathes for 7" x 32 to 36" x 18' with D.B.G. or S.B.G., some with taper attachments.

Lathes, Gap

1—C.M.C. 20" x 36" x 12' Q.C.G., D.B.G., taper attachment.
1—South Bend 21" x 30" x 7' D.B.G., taper attachment.
1—Perfect 12" x 17½" x 6' Gap Engine Lathe.
1—McDougal 22 x 40 x 18 D.B.G. Gap Engine Lathe.
1—Bertram 38 x 54 x 12 Gap Lathe.
1—LeBlond 33 x 60 x 16 D.B.G. and Q.C.G. complete with chucks.

Turret Machines

Milholland, Davis, Oliver make of various sizes and capacities, with full equipment.

Screw Machines

Foster, Prentice, Warner & Swasey and Cleveland, National Acme Automatics.

Drills

8—Woodward & Rogers 4-spindle, ½ in. capacity.
1—Edlund 1B High Speed Sensitive.
1—3-Spindle Silver Gang Drill.
1—20" Rockwell B.G. Power Drill.
1—20" Silver Drill, all geared.
2—20" Champion, all geared Power Drills.
1—36" Bertram B.G. Drill.
1—36" D8 Colburn Drill.
2—No. 1 Burke 10" Sensitive Bench.

Shapers

1—24" McGregor-Gourlay.
1—16" Rae Shaper.
1—14" McKenzie Shaper.
3—14" Davis Crank Shapers.

Grinders

1—12 x 42 Landis Plain Grinder.
1— 8 x 36 Fitchburg Cylindrical.
1—10 x 25 Q.C. Bath Universal.
1—No. 12 Gardner Disc Grinder.
1—Globe Universal Tool and Cutter Grinder
1—Stevens Universal Tool and Cutter Grinder.
1—Lafayette Universal Grinder for lathes.
2—Whitney No. 23 Internal Grinders.
Emery Grinders, Pedestal, bench type.

Millers

2—Briggs Type B42 Traverse (manufact'g).
1—Briggs Type A22 Traverse (manufact'g).
1—No. 1 Bertram Universal with Dividing Heads.
1—No. 2 Ford-Smith Plain Miller.

Compressors

1—12 x 13 Bury with tank and fittings.
1—10 x 18 Belt Driven Ingersoll-Rand.
1—8 x 8 Sullivan Compressor.

Shears, Punches, etc.

1—Ryerson No. 3 Rotary Bevel Shear, 1 in. capacity.
1—4 in. Stroke Double Arch Press Geared.
1—Lennox Rotary Splitting Shear, 24" stroke capacity, ½" plate.
Several small Punches and Shears to ½ in. capacity.

Hack Saws

1—Racine No. 10 Power Hack Saw, 8 x 8 capacity.
1—Peerless Power Hack Saw, 6 x 6 capacity.

Furnaces

1—Bellevue Double Chamber Oil Furnace.
1—12 x 15 x 8 Gas Furnace.
1—18 x 11½ x 8 Gas Furnace (West Magott).
1—24 x 18 x 12 Oil Furnace (Gilbert & Barker), with tank blower and pyrometer.

Miscellaneous

1—Morris Portable Crane, 1½-ton capacity, 10 ft. lift.
1—Canton No. 2 Portable 2-ton Crane.
1—Canton No. 2 Portable 1-ton Crane.
Several Hydraulic and Vacuum Pumps.
Several Blowers, Pressure and Exhaust Fans.
Grant Rotary Riveter, capacity 3-16.
Dividing Head for Miller.
Miller Vise.
Several Chucks.
Valve Milling Machines.
Transmission Supplies.
Several Greenard Arbor Presses.

Woodworking Machinery

We have complete stock of machines for all woodworking operations.

Boring Mills

1—Bement-Niles 66" 2 heads—25" under cross rail.
1—Niles 38" Vertical Boring Mill.
1—Bertram Horizontal 3½" Spindle, 60" between centers.
1—Universal No. 2½ Horizontal Boring Machine.

It will be to your advantage to let us have your enquiries

It Costs Money To Build High-Class Tools

President Newton Reviews the Outlook at New York Gathering—Necessary to Have Best Workmen to Keep Up the Standard—Cutting Prices Does Not Help Matters

ADDRESSING the nineteenth annual convention of the National Machine Tool Builders' Association at the Hotel Astor, New York, President Albert E. Newton, after reviewing the business situation, said that "any reduction in prices on machine tools will not stimulate demand, and is more likely to work to the contrary."

"For the past few months business in general has been on a down grade," stated Mr. Newton, "attaining greater velocity as the time went on, so that now, even if the brakes were set hard, we could not expect to stop the downward trend at once. Therefore, let us face the situation as it is, and realize that we are face to face with a real depression, and that the orders for machine tools are few and far between.

"Let us ask what are we going to do about it? Can we by any act of ours better the situation? The answer is 'no.' Most of us know from experience that the demand, or lack of demand, for machine tools is entirely beyond the control of the machine tool builders. We also know that any reduction in prices on machine tools will not stimulate the demand, and is more likely to work to the contrary.

"We should realize that the present condition of our industry requires us to be calm and courageous, think clearly and deliberately, and deal in facts and not theory.

"During the past five years the machine tool industry, as a whole, has not increased its prices as much as the costs have increased, and today our margin of profit is not on as a high a plane as it should be. Bear in mind that we must continue to improve our product, and that experimental and development work is a necessary part of the cost of machine tools. Also, that to produce a high-grade machine we must have high-grade workmen, and to secure and keep high-grade workmen, we must grant comparatively high wages.

"There is only one cause that I know of that should either increase or decrease the price of a machine tool, and that is cost, and I submit that our costs are today higher than ever before. It has been stated, and I believe it to be true, that the recent increase in freight rates will add 5 per cent. to this cost.

"We know that decreased production means higher overhead cost, so that even if our raw materials may cost us less in the near future (and I am not so sure that this will happen), this possible saving will be more than offset by the increased overhead cost due to reduced output.

"The depression with which we are now contending is no new experience for us, and is not a surprise, as we have been expecting it for some time; in 1913-'14 we experienced a situation in the machine tool industry very similar, if not wore than that which we are now passing through; that experience taught us the real value of our association, a value that has never, and can never, be too highly rated.

"I believe that most of our members fully realize that the values which accrue to them from the fruits of our association are proportionate to the time and mutual support given by them, and that our collective future as members of the National Machine Tool Builders' Association is dependent upon the unselfish and friendly co-operation of each individual.

Cancellations of Orders

"There is another important subject which always appears in times such as we have with us at present; that is, the cancellation of orders.

"It certainly would seem reasonable that an industry such as ours, which of necessity must purchase in advance its materials and supplies, sufficient to last for months, should be protected from indiscriminate cancellation of the orders on which it has based its plans.

"I hope that we may some time solve this condition and adopt some method that will raise the order for a machine tool to the dignity of a real contract, rather than a mere option that may be given up at will by the purchaser.

"It is an old saying, 'If you want a short war, prepare for a long one.' Let us attack this depression as though we thought it would last for some time; let us conserve our energies (meaning cash) so that whatever comes we shall be able to meet conditions in a business-like manner. Then we shall be ready to resume our full productive capacity when the demand for our product comes back to us, as it surely will in the not very distant future."

At the election of officers of the National Machine Tool Builders' Association, August H. Tuechter, of the Cincinnati-Bickford Tool Co., Cincinnati, was elected president, succeeding Albert E. Newton. Mr. Newton continues as a member of the executive committee. Other officers elected were: First vice-president, E. J. Kearney, Kearney & Trecker Co., Milwaukee, Wis.; second vice-president, C. Wood Walter, Cincinnati Milling Machine Co., Cincinnati; secretary, Carl E. Deitz, Norton Co., Worcester, Mass.; treasurer, Winslow Blanchard, Blanchard Machine Co., Cambridge, Mass.

Winnipeg Bridge.—The Winnipeg City Council are to be recommended by the civic committee on works to advertise for tenders for building the Maryland Bridge. Plans and specifications have been prepared and tenders must be made by December 14. It is specified that the bridge be completed ready for traffic by November 1, 1921, and that the entire structure, entailing railings and other features, must be completed by July 15, 1922. The final cost will approximate $300,000, and a penalty clause of $50 a day is to be included in any contract made. Traffic will be maintained over the bridge by temporary arrangements.

Plants Are Busy.—A despatch from Hamilton stated that one of the busiest spots there is at the National Steel Car Co. This concern has 844 men on its payroll, exclusive of the office and sales departments. While not a few Hamilton manufacturing plants have begun to retrench to a moderate degree, this large concern has found it necessary to put on a night shift, with the result that the important feature of its output is from 20 to 24 box cars per day for the government railways. These cars have a capacity of 40 tons. They are built to carry grain. Every afternoon the preceding day's output is hauled from the company's yards, and thence to Western Canada as fast as they can be taken there, to assist in expediting the movement of grain to the head of the lakes. In addition to the order for box cars for the government's railways, which was reported to be for 1,500, a large order has also been secured from the C. P. R. for flat cars. The C. P. R. has also placed its order for several all-steel sleepers. With the exception of the wheels, these sleepers, like all other cars built by the company, will be constructed completely at its local plant, and when shunted to its yards will be ready for service.

Thomas Findley, who for some years has held the dual office of president and general manager of the Massey-Harris Company, Limited, has resigned from the latter position, and in his place the board has appointed Thomas Bradshaw general manager. Mr. Bradshaw will be assisted by C. L. Wisner as assistant general manager in charge of sales, and by George Valentine as assistant general manager in charge of manufacturing. Mr. Findley, whose health has much improved of late, as president will continue to act as the company's chief executive.

BULLETIN ON REQUEST

General Combustion Co., of Canada, Limited

619-623 New Birks Bldg., Montreal

Trade Gossip

Howard S. Dick has been appointed city engineer of Kingston. He graduated from Queens in 1913, and was overseas with the Canadian Engineers.

Enlarged Foundry — The Canadian Hanson & Van Winkle Co., Toronto, have completed a large addition to their foundry, for the handling of gray iron castings, especially soft machine castings for the machine trade.

Have More Power.—The Hydro power cut in Kitchener has been reduced to 10 per cent. as the result of a number of industries agreeing to use electrical power at night. These factories have arranged to take a flat load over 24 hours rather than a heavy day load of 10 hours.

The United States furnished the entire supply of candles used in Cuba in 1918, which amounted to $1,492,027.

AUTOMATIC MILLING MACHINE

(Continued from page 482)

of helical gears and the main spindle gear is of herring-bone type, thereby eliminating tooth chatter. The overhanging arm is made in rigid form in the centre of machine, carrying a support extending to each arbor. Provision is made in these supports for a vertical adjustment. The cutter arbor is supported at its outer bearing in a phosphor bronze bushing.

The oiling system has been given special attention, all bearings being oiled from reservoirs. The spindle bearings are lubricated by sight feed drip oilers. In addition to the above there are three reservoirs with piping leading to other bearings of the machine. Reservoirs are provided with covers to prevent chips and dirt from getting into the same. Lubrication for the cutters is supplied by a geared pump. The vise is of a new design, its construction being very compact, without any loss of capacity. The driving pulley is 14 inches diameter and is driven from a countershaft, a 3½ inch belt being used.

PETROLEUM SITUATION

(Continued from Page 476.)

portation of oil from Baku is greatly reduced because of the lack of railroad transportation and the difficulty of passing through Georgia. The estimated production for 1919 is 1,257,000,000 gallons.

The average production of wells, which was 4,400 gallons per 24 hours in 1904 was 1,445 gallons in 1917, 1,165 gallons in 1918 and 1,730 gallons in 1919. Since the war the drilling of new wells has shown a constant decrease, falling from an average of 37,720 feet per month in 1913 to 13,120 feet at the end of 1917 and 1,400 feet at the end of 1918. For 1919 the average is still lower.

Meanwhile living expenses are very high, materials scarce and high priced; though the government is making every effort to relieve the situation, which is one that affects the industries of the whole world and especially those of the United States by the unprecedented demand the low output of the Russian oilfields causes to be placed upon those of the United States.

High Priced Coal.—Notwithstanding a general decrease in the prices of foodstuffs, Windsor dealers increased the price of anthracite coal to $26 a ton, approximately $10 more than the price being charged in Detroit. The difference in exchange and a shortage of coal are responsible for the step, it was explained.

DOMINION CHUCKS

STEEL OR CAST-IRON BODY
BUILT FOR HEAVY DUTY

All Screws Are Reversible

SCREWS are made of the best grade steel. Both ends are broached and are heat treated after machining. They are reversible, so that either end may be used, are large enough in diameter to stand the torsional strains applied by operator when setting up his work. They are made to give the best service—and may be depended upon to stand up under the hardest usage.

MACHINE WORK WANTED FOR LATHES, shapers, milling machine and planer, etc. Hourly or contract basis. Prompt delivery. W. H. Sumbling Machinery Co., Toronto. (ctfm)

PLANT WANTED

ENGINEERING WORKS WANTED—PREFERably in Ontario, to produce grading, excavating, road-building machinery. Advertiser will provide designs, patterns, etc., and is prepared to make contract immediately with suitably equipped firm. Replies should be in detail necessary to determine suitability of plant, location and the extent and nature of present manufacturing operations. Principals only dealt with. Box 710, Canadian Machinery. (c21m)

HELP WANTED

WANTED — ESTIMATING AND DESIGNING engineer for transmission towers, fabricated steel telephone poles, fire escapes and steel stairs. Give full information in first letter. Box 734, Canadian Machinery. (c22m)

WE WANT TO INTEREST SUCCESSFUL TRAvellers, at present covering Northern and Eastern Ontario with mechanical supplies, in a proposition offering unlimited possibilities capable of development into a main line. Box 735, Canadian Machinery. (c22m)

MACHINERY WANTED

WANTED—ONE 10 H.P. GENERAL ELECTRIC or Westinghouse motor, 60 cycle, 3 phase, 440 volts, 1200 R.P.M. The Frost & Wood Co., Ltd., Smith's Falls, Ont. (c24m)

Machinery Wanted

Advertisements under this heading will be inserted once free of charge. Readers are invited to use this department when in need of equipment. Replies may be sent to box number, care of Canadian Machinery, if desired.

For Sale

One 52-inch John Bertram & Sons Co. Boring Mill, late pattern, with two heads on the cross rail, with independent jaw chuck built into the table, arranged for motor drive using ten horse power motor, without motor.

In use at the present time on very fine class of work. Price $6,450.

Box No. 729. Canadian Machinery. (C23M).

FOR SALE

ONE 5 H.P. JONES & MOORE, 1440 R.P.M. motor, and one 10 H.P. Canadian General Electric Company's 1500 R.P.M. motor. Both for 25 cycle, 550 volt, 3 phase current; 10 H.P. motor equipped with standard oil-immersed starter with no voltage release attachment. Both in good condition and may be had at a reasonable figure. Mathews Gravity Carrier Company, Limited, Port Hope, Ontario. (c22m)

FOR SALE—ONE BURY AIR COMPRESSOR, 12 x 14, Class M, 330 cub. ft. per minute, belt driven, only slightly used, $750; one air compressor tank 42 in. x 8 ft., man-hole on top, two 4½ in. side openings and one 2 in. side opening, $100. Taylor-Forbes Co., Ltd., Guelph, Ont. (c23m)

BELTING—AT LESS THAN USUAL PRICES. All sizes up to 24 inches in width. 3-inch, 4-ply new rubber at 30 cents; 4-inch, 4-ply at 35 cents; 5-in., 4-ply at 45c; and 6-in., 4-ply at 50c.; 4½-in., 4-ply, new stitched canvas at 30 cents; new, solid, tooth circular cordwood saws, 30-in., at $9.50, and 28-in., at $8.50. N. Smith, 138 York St., Toronto.

ONE 24-IN. DIA. x 48-IN. STROKE SIMPLE horizontal side crank Corliss steam engine, with 20-ft. x 25-in. flywheel and outboard bearings, made by Wood, Bolton, Eng.; one Northey jet condenser, 10-in. steam inlet, 8-in. water inlet, and 8-in. outlet; one London Machine Tool Co., 24-in. x 24-in. metal planer, single head, 6-ft. table, power cross feed, hand vertical feed and countershaft. Apply The Nova Scotia Underwear Co., Ltd., Windsor, N.S. (c24m)

PATENTS FOR SALE

R. M. WHITE, TITULAR TO CANADIAN Patent No. 202132, dated July 20th, 1920, relating to stair-climbing hand truck, wishes to dispose of his full rights and privileges in Canada. For further particulars apply to Adrian A. St. Laurent, I.E., Patent Broker, 75 Stewart St., Ottawa, Ont. (c22m)

HENRY R. ADAMS, TITULAR TO CANADIAN Patent No. 204044, dated September 21, 1920, relating to a gramophone reproduction device, wishes to dispose of his full rights and privileges in Canada. For further particulars apply to Adrian A. St. Laurent, I.E., Patent Broker, 75 Stewart St., Ottawa, Ont. (c22m)

CASTINGS

Medium and light, grey iron castings for manufacturing purposes. We carry bushings, solid and cored, from 1 in. to 6 in., or larger.

TORONTO FOUNDRY CO.
1884 Davenport Road, Toronto
(c31m)

FOR SALE USED MACHINERY IN A 1 CONDITION

1—16" Hendey Shaper.
2—18" x 8' Mueller Lathes.
1—18" x 8' Cincinnati Lathes.
1—26" x 12' C.M.C. Lathe.
1—24" x 10' Milwaukee Lathe.
1—32" x 24' Engine Lathe.
2—3 x 36 J. & L. Turret Lathes.

We are offering the above machines at very attractive prices. Write us for quotations on your requirements.

CHARLES P. ARCHIBALD & CO.
Machinery and Supplies
285 BEAVER HALL HILL, MONTREAL

PATTERNS

TORONTO PATTERN WORKS, 65 JARVIS Street, Toronto. Patterns in wood and metal for all kinds of machinery. (ctfm)

BRANTFORD PATTERN WORKS ARE PREpared to make up patterns of any kind—including marine works—to sketches, blue prints or sample castings. Prompt, efficient service. Bell 'Phone 631: Machine 'Phone 733. Brantford Pattern Works, 49 George St., Brantford, Ont. (ctfm)

AGENCY OPPORTUNITIES

WE ARE FREQUENTLY ASKED TO SECURE representatives for manufacturers in Canada, Great Britain and the United States. From time to time we shall publish particulars regarding agencies available and correspondence is invited. If the information has not been previously supplied please give particulars regarding experience, sales organization, territory, etc.

AMERICAN MANUFACTURER OF SANITARY drinking fountains who has made arrangements to have his line manufactured in Canada wishes to get in touch with a man who can sell the appliance in industrial plants of all kinds. Box 730A, Canadian Machinery.

CANADIAN AGENTS WANTED

FOR HIGH-GRADE AMERICAN-MADE LATHE —14 to 26. In replying state territory you can cover and cover thoroughly. Box 682, Canadian Machinery.

CANADIAN REPRESENTATIVE WANTED by U.S. manufacturer of well known line of high speed and alloy steels. Correspondence invited and will be treated as confidential. Box 707F, Canadian Machinery.

SALESMEN WANTED

Must be thoroughly familiar with the Foundry and Coal Mining Trade. Box 719 F, Canadian Machinery.

HARDWARE AT
REDUCED PRICES.
VALVES
PIPE & RAILING FITTINGS
IRON BARS
MACHINE BOLTS
BABBITT.

MANUFACTURING NEWS

VOL. XXIV. No. 23 December 2, 1920

Drop Forging

A Short History of Forging is Given, Together With Various Examples of Drop Forging Practice. These Examples Include Axles and Crank Shafts.

By J. H. MOORE

FORGING is at all times an interesting study, so before describing the new portion of the plant of the Canada Forge Co., let us delve for a short while into the art of forging itself.

The art of forging iron and steel by power hammers was introduced to America about the year 1850. This discovery proved so successful that research work was immediately commenced, with the result that forging has now become a scientifically developed art, and one of our important mechanical industries.

There are two commonly known types of forgings, namely, drop forgings and flat hammer forgings. The former type are so called because they are forged in dies under vertical power hammers, operated by efficient hammermen, while the latter class are made under either powerful steam driven hammers or hydraulic presses, operated by hammersmiths. Flat hammer forgings are usually of quaint and unusual design, and, of course, as can be understood, no dies are used. This is why the operators are called hammersmiths, and they must be smiths in every sense of the word to produce good work. This latter class of work is indeed an art, because forgings of unusual shape are being continually required in one piece from the very smallest up to forty tons in weight. It is easily seen that highly capable men only can be employed on such work.

The hammers used vary. Some are capable of striking each blow equal to from one-quarter of a ton to 60 tons. The hydraulic presses can in turn exert a pressure from one-quarter of a ton to 12,000 tons, if necessary. Take for example some ship and locomotive parts. These are so heavy that the hammersmith and his crew require power rotating devices and electrically driven cranes to handle the material to and from the furnaces, until the desired shape and dimensions are completed. The hammersmith is the man who must use his skill and judgment as to whether a light or heavy blow is required. While at the plant (later to be described), the writer saw them working on some huge billets 36 inches in diameter, and handled by rotary device, and it was a treat to watch the work proceeding. In this case a hydraulic press was used of 6,000 tons capacity.

Steels and Their Treatment

Wrought iron was at one time considered the best material for forgings on account of its ductility, and the great amount of vibration it could withstand before crystallization would set in. There are still uses for it, and in some cases it is claimed to be superior to

FIG. 1—THE BILLETS BEING HEATED.

FIG. 2—WORK COMING FROM THE ANNEALING OVENS.

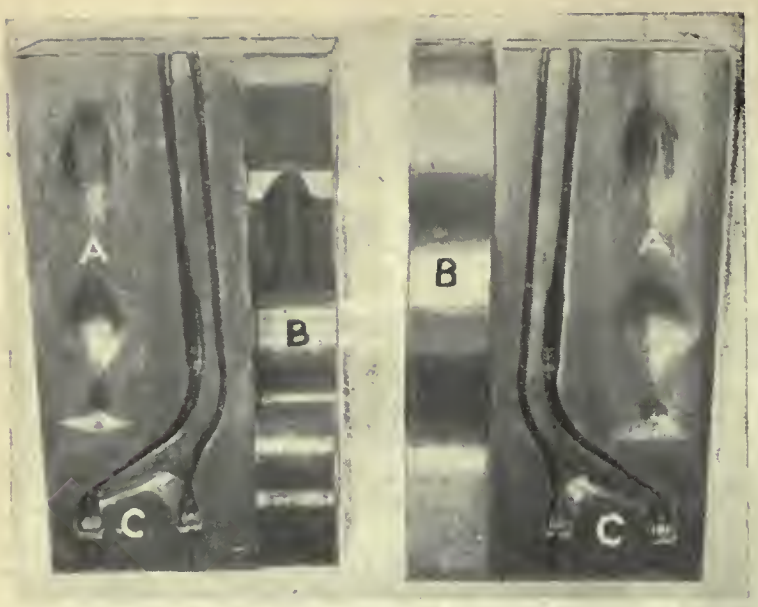

FIG. 4—DIES USED TO PRODUCE THE FRONT AXLE OF AUTOMOBILE.

other metals. Such cases are hull forgings for ships, stern frames, posts, rudders, etc. Modern engineering practice, however, with its demands for greatly increased loads and hard service, requires, for certain parts of heavy machinery, forgings which will have two or three times the strength and rigidity of iron, and will at the same time combine with these qualities the factor of ductility. These qualities are to be found in what is generally known as open hearth steel forgings.

The steel must, of course, be of proper chemical analysis for the purpose required. In the case of small forgings, rolled steel billets are used and worked to shape under steam hammers, while the larger work from steel cast ingots is generally done under hydraulic presses.

It is a well known fact that the working of the hot steel not only provides a means of shaping it to form, but at the same time refines the grain structure, and tends to increase its density and dynamic strength. The steel is first heated to what is known as the critical range of temperature, and in order to acquire the best results the finishing temperature in working should be just within this critical range, in order to increase the elastic limit and the period of endurance in service of the forging. This range of course depends upon the nature of the steel.

During the process of working, and the alternate cooling, internal stresses and strains are created, which can only be neutralized and made homogeneous through heat treatment in special furnaces regulated usually by electric pyrometers. The importance of heat treatment is to make the steel possess certain physical properties best suited to the purposes intended, and this is accomplished by increasing its ductility, elastic limit, and tensile strength.

To obtain proper heat treatment, you require, what is obvious, namely, good material, proper equipment, and a knowledge of correct procedure. Experience is a great thing in the art of heat treatment. This plant does its heat treating in car type overfired furnaces. This style of furnace removes all forging strains and stresses, thus insuring the greatest degree of safety by still further refining the grain and creating a higher degree of toughness in the finished forging. All the forgings at the plant we speak of are thoroughly tested and inspected before being permitted to leave the factory.

The foregoing information has been mostly on their flat hammer work, and before leaving the subject, let us look at Figs. 1 and 2. In the first view we see two billets being heated in the furnace, while in the second picture we notice some of the work which has just been annealed. The size of these forgings is self apparent, and a good method of comparison is to look at the size of the crane chain links, then study the size of the work. It might be well to add that this concern make practically all their own furnaces, and use burners of their own design.

Before the material is used for forging purposes, it undergoes a severe test in the chemical and testing departments. An analysis is taken of all material entering the plant, and every particular is known and indexed on file. Usually the chief constituents are marked on the end of the billet as it rests in the yard. For example, the writer saw one particular billet which was marked Chrome 1.37, Nickel 3.02, 22" x 22" x 7'-2". 11900 lbs. This information gives the smith all necessary data for his purpose.

Drop Forging

And now, having touched on the flat hammer work, let us consider some examples of drop forging practice. The first example depicted is the heading. This shows a separator stem made for

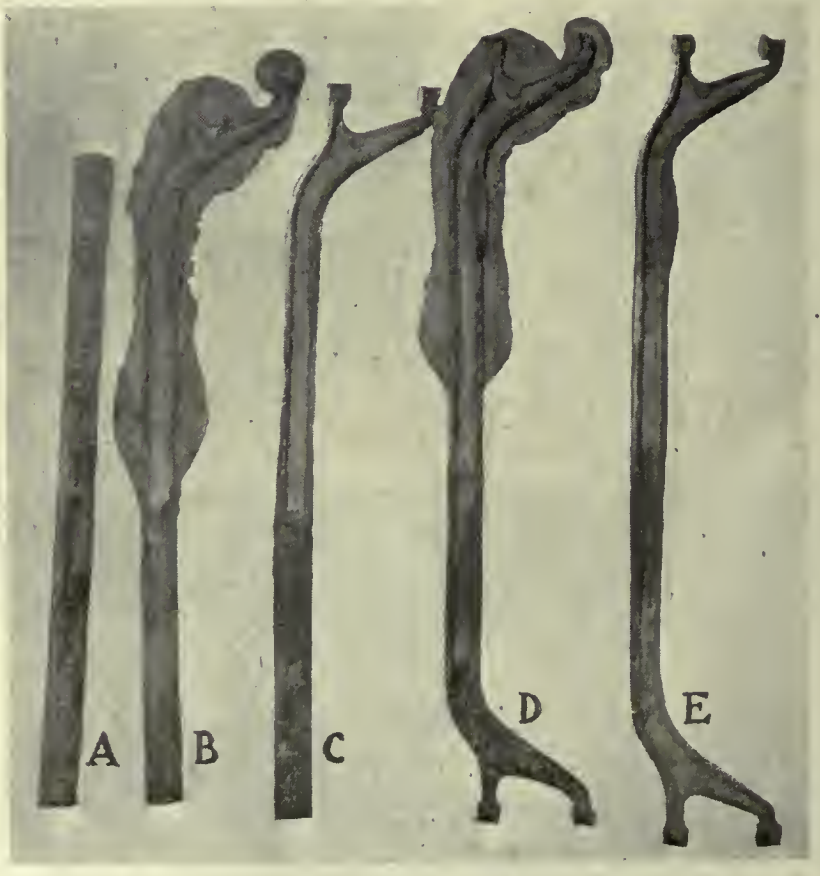

FIG. 5—THE VARIOUS STEPS NECESSARY TO COMPLETE A FRONT AXLE FOR AUTOMOBILE.

the Massey-Harris Co., and its method of manufacture is very interesting.

The work is first heated in the furnace, and this is done in a furnace of double construction of their own make. It is equipped with four burners of their own design, and by means of these burners the furnace can be run 10 hours on 24 gallons of crude oil. This is a splendid record, and speaks well for the burner construction. The billets are heated from 2200 to 2300 degrees Fahrenheit, and the hammer used to drop them to shape is of 6000 lbs. capacity. It might be well to explain that the billet is 3" square and 13" in length, thus allowing for the making of two stems.

We will suppose the billet has been heated and is ready for the hammer. The following steps are now followed out. The stock is first edged down near the middle of billet on the portion of die marked A. It is next placed over the center impression of bottom die B and the blows struck. Usually 6 to 7 blows complete the form. After this, it goes to the trimming press and is trimmed.

This operation is worthy of special mention as a hydraulic press of 150 ton capacity is used. This press was employed during the war for shell work. They simply switched it over to peace time duty, and as they had it all piped up and the water there, it costs practically nothing for maintenance. Of course such a press could not be used in the average case, but the fact of its being in use makes it worthy of mention.

The fash is next cut off at end of billet, and the hammer makes a tong hold on the remaining stock. It now goes back into furnace and after reheating, the operation is repeated. Twelve billets are carried at one heat of furnace, or in other words, 24 forgings. The production of this piece is 300 stems per 9 hour day, and in the making of the die some 1800 lbs. of steel are used.

The next photograph, Fig. 4, depicts the die used to forge the front axle of the McLaughlin Buick Car. The billet in this case is 2½" diameter, and 41¾" long in its rough state. To further explain the procedure in forging of the axle we have prepared Fig. 5, which illustrates the various steps in its progress.

The stock is first placed into what is termed the roller (see A) to gather balls, or a greater amount of stock in certain sections, and reduce the amount in others, so as to distribute it properly to place in the binder, or second portion of die (see B). The purpose of the second form is to bend the stock up in proper shape so as to fit the third impression C as closely as possible. It is now placed over final impression C, and hammered to shape. Usually six to seven blows are sufficient. This view shows the roughing set of dies only, and as will be noticed, takes care of only one-half of the axle. This is the method of making these axles one-half at a time.

After half of the axle is rough finished, it goes to the finishing die, this consisting of but one impression. Five or six blows bring the forging to correct form, and the axle must be correct as to bosses, pad and web of beam. From here it goes to the trimming die to remove fash, or surplus material. It is then returned to the hammer and restruck, as sometimes the trimming die will bend the forging. The other end of axle now goes through similar operations.

After leaving the hammer the axle next arrives at the bulldozer. It is practically impossible to forge a piece of such nature to accurate length, so that this is where the bulldozer comes in nicely. The forging is made a shade heavy on the beam, and in this last operation the bulldozer stretches it to exact length, and makes sure all pads are correct. In action, here is what happens.

The axle is placed in a form of correct shape, up comes the moving head, and a spreader strikes the center portion of axle, thus spreading it to accurate length. The axle is gripped tight on each end by clamps shaped to suit the web. The spreader has two rollers on it which engage with tool steel tapered guides. These spread, and in turn spread the axle. While this occurs two rams attached to the die heads flatten the spring pads. This operation eliminates any machine work on these pads. The machine can turn out 450 axles every 9 hours, and the production on the hammers is as follows: 400 ends blocked and 400 ends finished every 9 hours.

The forgings used in the axle making are blocked in one hammer, taken over to the furnace of second hammer, then heated there. This saves a great amount of heat, and the two hammers, namely blocking and finishing, work in tandem. It is estimated that 75% of

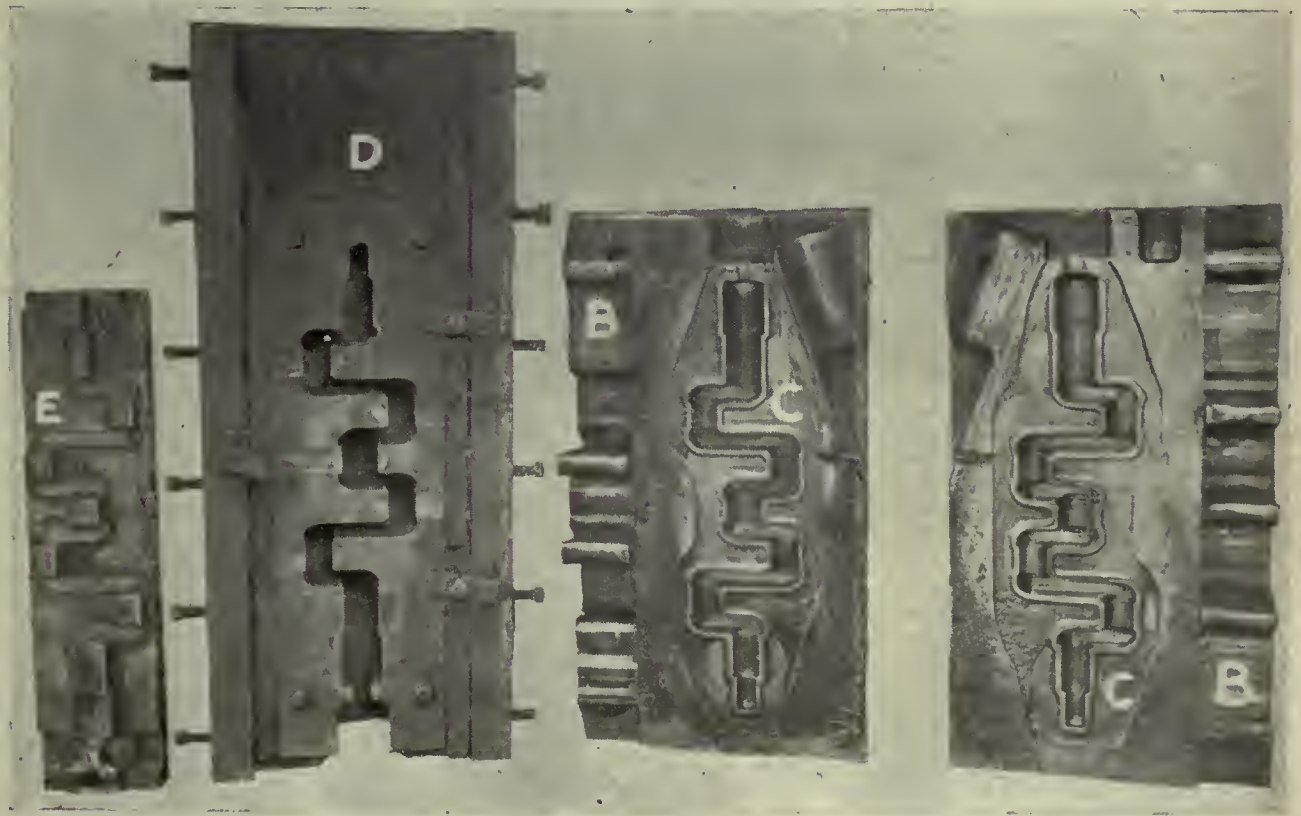

FIG. 6 THIS SHOWS BOTH DROP FORGING AND TRIMMING DIES USED ON AN AUTOMOBILE CRANK SHAFT.

FIG. 7—STEPS IN THE MAKING OF AN AUTOMOBILE CRANKSHAFT.

heat is saved in this way. For example, when the first operation is completed, the forging is still a cherry red. This being so, it does not take long to heat it up to the proper forging heat for finishing operation.

The bending impression B (see Fig. 4) is not made with any idea of forming to finished shape, but the idea is rather to have sufficient stock at the correct place to form up nicely on the impression C. The dies which we have just been discussing required two tons of steel to make them, and cost in the neighborhood of $1,500. Referring to Fig. 5, we note that A represents the rough stock, B one-half of axle rough forged, C one-half finished forged and trimmed, D the other half rough forged, and E the completed axle. These steps, together with previous description, will no doubt be perfectly clear.

Crank Shaft Die

The next example, Fig. 6, depicts the dies used to produce the crank shaft for the Chevrolet Baby Grand. In this case they use stock 3½" diameter, and draw it down to 2½" diameter on both ends. This is accomplished on breakdown, or swedger, shows at extreme side of each die block, see Fig. 6. This portion of die prepares the stock for the finishing impression. The stock as it appears after the swedging operation is shown at A, in Fig. 7.

Let us again refer to Fig. 6. The stock is next placed in the bender at B, when it is formed up to shape and rough outline of impression. It is next placed over the finish impression C, and struck sufficient blows to bring to required size. From this operation it goes to the trimming press and fash removed. These trimming dies are shown at D and E and they are so designed that forgings will drop through freely. After trimming, the piece is returned to hammer and restruck to make sure there is no twist in the crank.

From here it goes to an upsetting machine, which has a pressure of 200 tons. The stock is inserted in the lower die of the machine, and a vertical ram with upper die attached grips the crank firmly. The horizontal ram now comes forward, and a heading tool enters the die and upsets the flange shown at C in Fig. 7. B in this same view illustrates how the crank appears before upsetting. This flange is completed with one stroke of the ram. In the forging operation 180 cranks are completed in 9 hours, and 350 are upset in a similar period.

Designing Dies

Before proceeding with further examples of dies, it might be well to explain that this concern prepares all their own dies, even to supplying the steel for the same. They are, in other words, a self-contained organization. They have a die sinking department, a tool room, a machine shop, etc. These various units are all in Welland and under the heading of the Canada Foundries and Forgings, Ltd.

Suppose, for example, that a new piece comes into the plant, which has to be drop forged. The following vital points must be observed. First, the blue print, or sample, must be studied and measured in order to decide the size and width of block to be used. As a general rule, on a heavy hammer such as the 6000 lb. we have been speaking of, a die block is never made less than 12" deep. This, of course, is in order that the block will be able to resist the strain exerted on it. The width must also be sufficient to withstand strain, apart from the planning of proper width to accommodate the main impression, and other operations such as bending, edging, rolling, etc., etc. The rolling, by the way, is really the gathering of the stock in a certain place, as for example in Fig. 4, at A. Another general rule is to leave at least 3" of each side of impressions.

Having decided upon these points, a

FIG. 8—SINKING A CRANK SHAFT DIE.

templet is made from the drawing and the dies are all laid out from these templets. The laying out and die sinking is done as a rule by one man, and the average time, on, say such a die as the crank shaft die shown, is approximately 40 to 50 hours. Take for example, Fig. 8. Here we see the operator cutting out, or to use the proper expression, sinking a crank shaft die. A roughing tool is first employed, after which a 7 degree cutter finishes the work. Where awkward shapes occur, such as semi-circular grooves, a cherrying attachment is often employed. After die sinking is completed, the die goes to the bench and there is filed and smoothed with fine emery paper.

The die shown in course of preparation is for the McIntyre Motor Co., Kalamazoo, Mich., and the shaft measures 34⅞" over all. We give these dimensions in order that readers can form some idea of the general proportions of the

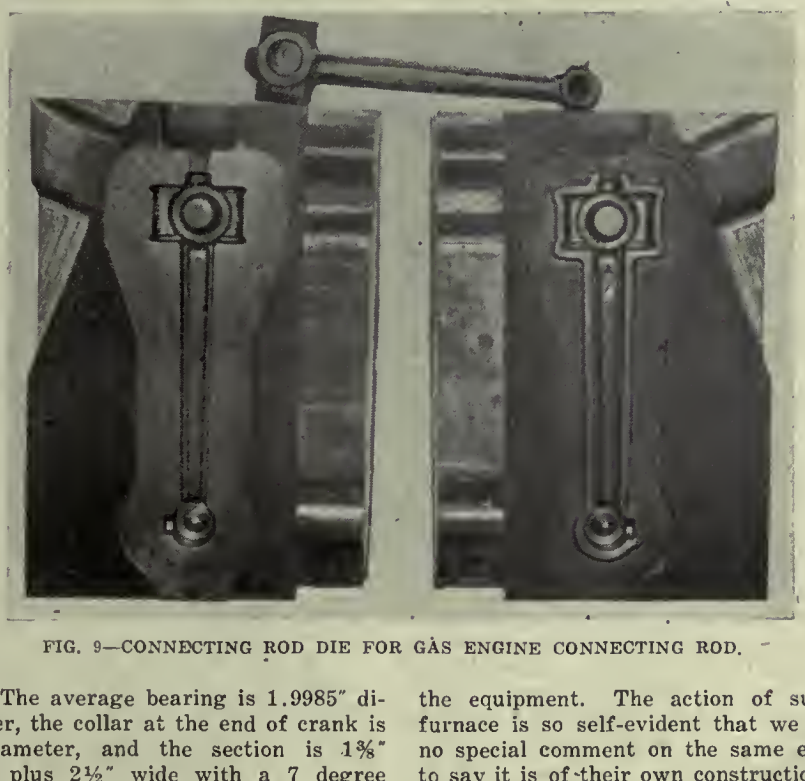

FIG. 9—CONNECTING ROD DIE FOR GAS ENGINE CONNECTING ROD.

die. The average bearing is 1.9985" diameter, the collar at the end of crank is 5" diameter, and the section is 1⅜" thick plus 2½" wide with a 7 degree flare.

Another Example

The next example, Fig. 9, illustrates the dies used to forge a 1½ h. p. gas engine connecting rod for the Kerr & Goodwin Co., Brantford. The steel for this job is approximately 1¾" square in the rough and it goes through the following steps in sequence. The center of stock is drawn down at corner of die, then is placed in edger. This rolls the stock to proper shape and size. It is now placed in finish impression and blows struck. It is next trimmed, from there going back to the press to be straightened. It now goes to the punch, and has the eye punched out, thus completing the rod, as far as they are concerned. The rod is 11⅝" center to center, and the web is of I section, approximately 15/16" wide, with 3/16" thick center web. These few dimensions will be sufficient to allow readers to form their own ideas as to complete proportions of the die.

Other Features

In conclusion, let us refer briefly to some of the equipment used in this new drop forge plant No. 4, as it is called. The building itself is 80 ft. x 220 ft., of steel construction, with concrete floors throughout. Two 6000 lb. steam drop hammers, two 200 tons hydraulic presses, one 5" upsetter, one 60" bulldozer, two electric trucks, one 15-ton electric crane, and of course the attendant die sinking department.

The steel used on their die blocks is made from Ni-Krom die block steel, and, as stated before, is of their own make. An automatic furnace is also at present being installed, and this in itself will be an important addition to the rest of the equipment. The action of such a furnace is so self-evident that we make no special comment on the same except to say it is of their own construction.

The machine shop connected with this portion of the plant accomplishes the rough and finish machine work if desired, and is well equipped for both large and small work. In addition to the chemical and test departments, a fine first aid room is installed, and in this room is even the equipment necessary for operations should they be required. The workers in charge of the department are ex-army medical men, who thoroughly understand their business. While this new portion of plant was primarily intended for making forgings for automobile work, it is well equipped to handle any work of a forging nature, and we are led to understand that still further additions will be made as soon as working conditions permit.

COMPRESSED AIR OPERATES STENTORIAN PHONGRAPH

New uses for compressed air are being almost constantly found in the basic industries and in specialty manufactures, comprising largely of course the utilization of well known principles in compressed air practice. Occasionally an entirely new idea comes to the fore, one of such that has lately come to light being from the fertile brain of Gaydon, a British engineer. Mr. Gaydon has demonstrated his invention of a phonograph with a voice that would even wake up our commerce board.

It is reported that the inventor tested the voice of the machine on his neighbors in a London suburb, and that the tune played could be recognized by auditors more than two miles distant. The instrument is called the "stentorphone," after Stentor, the Greek herald, who was reputed to have a voice like reverberating thunder.

Compressed air and a new species of sound box are declared to be the secrets of the invention. The air is supplied by means of an electric motor, and when it passes through a small valve controlled by the phonograph needle, it expands and creates a burst of sound that in the case of vocal selections, at least, surpasses by many times the volume of the original voice. It is said that to a person standing about 30 yards from the instrument the illusion of a brass band playing at about an equal distance is almost complete. The most entertaining results, however, are derived, when a vocal phonograph record is placed on the stentorphone. At the time of the public test, when Sir Harry Lauder's "We Parted on the Shore" was played, it sounded like the voice of the mightiest giant that ever stalked through the pages of a fairy tale, according to the reports.

Mr. Gaydon thinks that the machine can be used as a drill sergeant, giving the words of command before playing the marching accompaniment. In battle it might be used to drown out the shrapnel crescendo and scare the enemy to death, is another militant suggestion. It has also occurred to the inventor that possibly it can be used to deliver the speeches of political candidates in a way that will baffle the obstructive tactics of the loudest-voiced and most persistent heckler.

The Federation of British Industries has devised a unique scheme for advertising home manufactures in all parts of the world. A new steamship, to be called the Federation, is to be constructed by some of the leading firms of the country as an exhibit of British marine engineering. The cargo of the ship will consist of various articles of British manufacture. Representatives of the firms interested will make the voyage for the purpose of showing their goods and interviewing foreign buyers.

Some Interesting Machine Shop Problems

Various Problems on Machining Bearings Are Solved, Also the Fitting of Brass Lines for Marine Propeller Shafts—A Simple Centre Jig is Described, and Other Ideas.

By JOHN S. WATTS

THE notes that follow are on a variety of topics, connected only by the fact that while all the points made were common knowledge and practice with the old time all-around machinist, my experience with the younger mechanics leads me to believe that they are unfamiliar with much of the useful knowledge acquired by their predecessors, when a man usually followed a job through to actual operation, and so gained experience which is not generally available to the mechanic of to-day.

The lack of technical schools and journals in the years past had a tendency to make the mechanic of those days a man who studied things out for himself, and acquired a habit of analytical study which enabled him to arrive at the correct solution of any problem which he encountered. On the other hand, I find that knowledge gained from the experience of others does not become a part of oneself, and is not so thoroughly grasped as that which has been acquired by the use of one's own intellect.

While it would be absurd to condemn the training of apprentices, it unfortunately does tend to weaken their self-reliance, and the mechanic of to-day, will, 99 times out of a 100, refuse to tackle a job which he has not been taught to do. This is a fault which he should fight against. and is in the last analysis simply a form of mental laziness, as the well trained and educated mechanic of these days should, with his wider knowledge of the laws of mechanics, be more able to handle the unusual job than his predecessors. The only advantage the older men had was that they were naturally used to taking on any job that came along, having never had any assistance from teachers or books.

A case in point came to my attention a short while ago in a shop finishing large marine propeller shafts. The brass liners are about 12 inches diameter, and anywhere from four to six feet long, and after boring out are heated and shrunk on to the shaft. These people were losing the liners, sometimes three or four consecutively, on the same shaft, by reason of the liners developing a crack circumferentially when cool; this cracking they attributed to the material, as they thought a crack caused by a shrinkage strain would be a longitudinal one.

Now in the shop where I served my aprenticeship we were turning out propellor shafts continuously, and I never saw one crack, and this although they were made of common yellow brass, nearly all scrap, while the ones mentioned above which did crack were the 88-10-2 mixture cast of all virgin metal, and subject to analysis.

Investigation showed that both the shaft and the liner were rough turned, and no attempt had been made to get a smooth surface where the liner fitted. Considering that at the temperature at which these liners are shrunk on the shrinkage longitudinally will be around one-eighth inch per foot, or ¾-inch on a six foot liner, it is clear that either the liner must slip along the shaft as it cools, or crack circumferentially as actually happened. Having been used to shrink fits whose length was comparatively short, it did not occur to them that the liners had to shrink in length as well as in diameter, and the solution of their trouble was obviously to turn both shaft and liner smooth enough to allow the liner to slip along the shaft when contracting.

Another Case

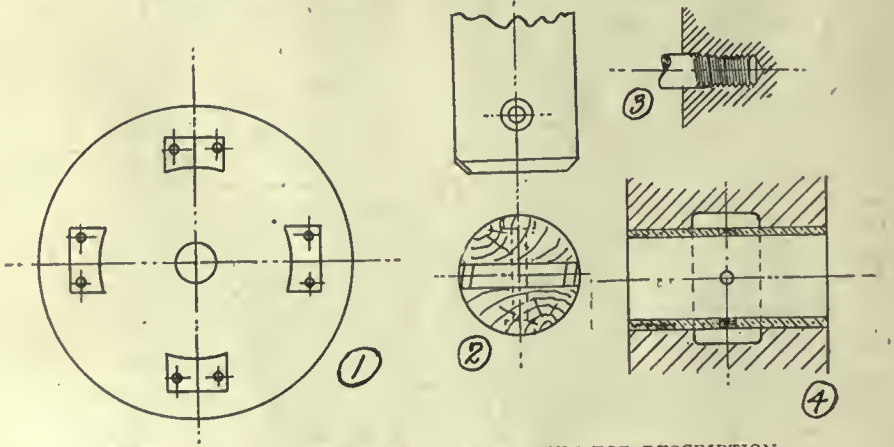
Before mass production reached its present dimensions, it was common practice for the machinist to devise his own jigs, and generally to decide as to whether it was worth while to fix up a jig or not. The practice now seems to be that if no jig is provided the machinist makes no attempt to improvise one. For instance, even the smallest shop will at times get a quantity of wheels, flanges or similar circular castings to bore out, and to true up each individual piece in a chuck is a waste of time, even if only six are required. By taking three or four short pieces of bar and after bolting them to the face plate, bore them out to the diameter of the casting, as shown in Fig. 1, we have a jig which will centre the castings accurately enough for ordinary work, at a trifling expense. The casting is then clamped to the face plate and the time spent in trueing up is eliminated.

For boring out plain solid bearings, when the quantity is too small to warrant the expense of a special jig the best method is to bolt an angle plate to the face plate, at a distance below the centre of the lathe equal to the height from the base of the bearing to the centre of its bore. Also drill holes in the angle plate to match the bolt holes in the base of the bearing, and we are then assured that all the bearings so machined will be alike as to centres.

While on the subject of bearings it should be noted that solid bearings for hand operated, or slow moving gearing, such as chute hoists and the like, where the bearings are bolted to the wood work of the building or structure, should be bored out one-sixteenth of an inch larger than the shaft, to allow for mis-alignment, due to the possible warping of the wood and settlement of the structure. To the man who has not had the operating of such mechanism this may seem like sloppy work, but actual experience dictates this clearance as essential for really satisfactory performance.

A point often overlooked in the machining of gears, bearings, etc., which are called for in the drawing to be faced, on one side of the boss only, is that it is not correct to merely machine off enough to clean up the surface. It is necessary that the distance from the centre line of the gear, or of the bearing, to the machined face, must be as shown on the drawing, or the erecting crew will have trouble, and this dimension should be worked to in machining.

When a parallel or taper reamer, of a size not available, is wanted in a hurry, one can be made up very quickly by turning up a piece of flat tool steel, and fastening to it hard wood blocks as shown in Fig. 2. The shank can be made square or tapered to suit the driving medium and a reamer so made will do



FIGS. 1 TO 4 INCLUSIVE—FOLLOW THE TEXT FOR DESCRIPTION.

a surprising amount of work of a high quality before being worn out.

Some Other Ideas

Cases arise occasionally when a stud has to carry its load in shear, and if screwed in in the usual way the area to resist shear is only that at the bottom of the thread, and it is further weakened by the sharpness of the thread, which tends to make it easy to shear off. This can be improved upon by counter-boring the hole about ½-in., as shown in Fig. 3, to the neat diameter of the stud. The stud is then screwed in until the end of its threaded part is at least ¼-inch under the surface, the result being that the solid part of the stud now takes shearing strain.

For heavy pressures or for places where the joint would be hard to get at, if a leak should start, a sure job must be had, and the safe way is to spot face the casting under the nuts and bolt heads, thus getting a greater tensile strain on the bolt with an equal pull on the wrench, due to the lesser friction under the nut, with a smooth surface. The nut and bolt head under these conditions will also give a better support to the flange, against springing under the pressure. When heavy bolts are used, ¾-in. diameter or over, additional safety can be gained by slightly heating the bolts, so that they will shrink after being tightened up by hand.

It would seem that a shaft coupling, shrunk or pressed on a shaft would remain true, after driving the key, but experience shows that the driving of the key will often throw the coupling out of line slightly, and it is good practice to true up the coupling after it has been keyed to the shaft. Cases of hot bearings, in line shafts, otherwise mysterious, may often be traced to the coupling being forced out of true when the key was driven.

Loose pulleys, ring oiling bearings and such, where the inside is cored out to form an oil reservoir, should have the rough surfaces carefully painted over to prevent any of the moulding sand adhering to the surface, afterwards becoming loosened and getting mixed with the oil. A good idea in loose pulleys and rollers is to drill about six holes in the bush and plug them with felt, this will keep the oil from running out of the reservoir, and provide a continuous feed of clean oil to the bearing; the general idea is illustrated in Fig. 4.

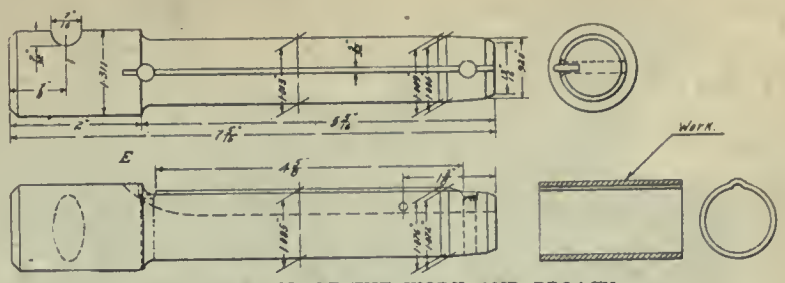


FIG. 1—DETAIL OF THE WORK AND BROACH.

OSCILLATING BROACHING FIXTURE

By "Draughtsman."

THE operation is to broach a piece of drawn brass tubing 2 inches long, 1 inch inside diameter, and 3-32 inch thick, and to form a small fluting running its whole length, as in Fig. 1.

The piece is subsequently punched for an oil hole and then pressed into the end of a wooden connecting rod, thereby forming a bush which cannot turn because of the fluting, which also acts as an oil groove. The operation is accomplished on a press of 3 inch stroke, and the fixture is designed so that one piece is broached and another ejected per stroke.

The upper holder B carries a broach C and a pusher D. The broach, shown in detail, has an inserted blade E held by two pins. The enlarged head butts against the counterbore shoulder, and is prevented from turning by a "half-and-half" pin. The pusher is simply a pin shouldered at its upper end and held by a set-screw. Its body is slightly less in diameter than the brass tube, and its lower end is shouldered and reduced to a short centering taper.

The bolster F has a recess in which rests the hardened die block G. By means of a lever H and handle it can be rotated through 180 degrees, its movement being limited by stop pins J. The dieblock is retained by a steel ring K. The stationary stripper plate L has two bushings, the first one M, under the broach is fluted to suit the work, and resists upward thrust, while N, the one under the pusher, has a plain hole and resists downward thrust. The front part of the stripper is reduced in thickness to give ample room for the operator's fingers. The broach hole in the bolster carries a heavier bushing O to take the thrust of broaching, while a clearance hole P under the pusher communicates with the hole in the bed of the press.

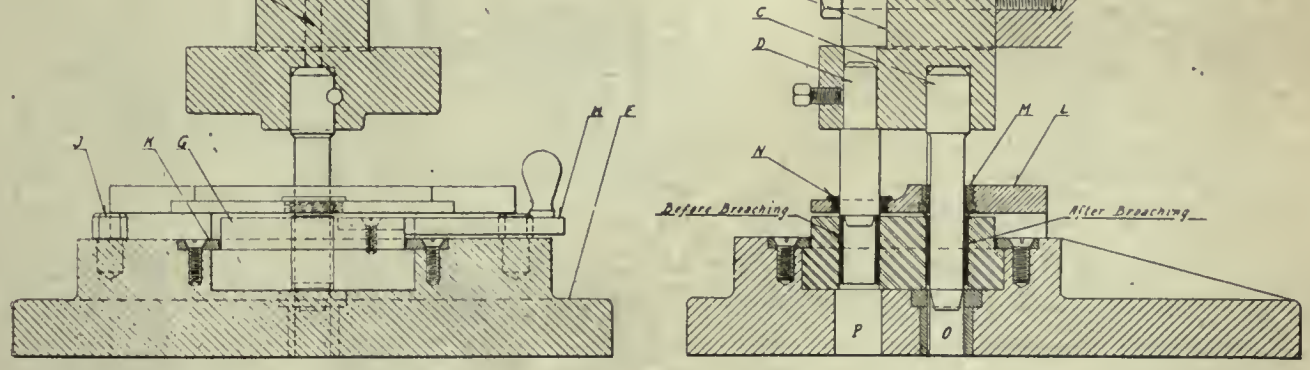
Operation

With the ram up and lever over, say to the right, loosely insert bush No. 1 in the hole under the pusher. Trip the press and the pusher will force the bush into the die-plate.

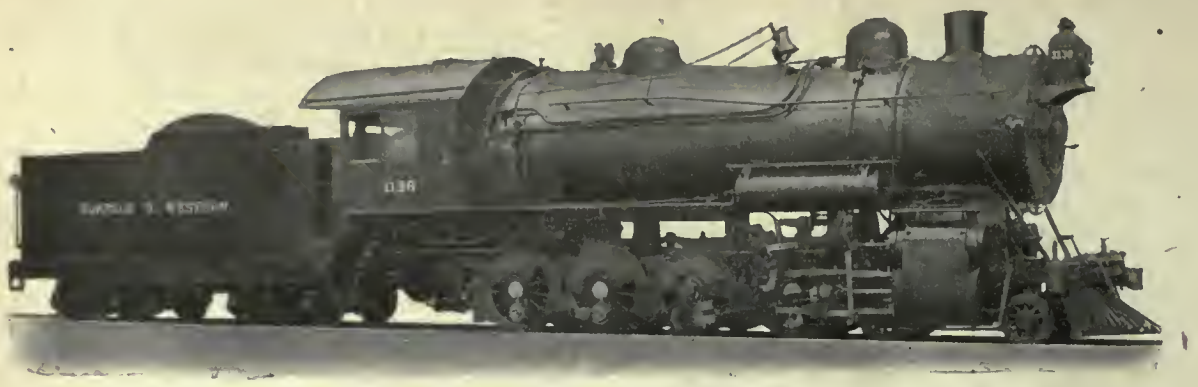
With the ram up, swing the lever over to the left and insert bush No. 2 under the pusher. Bush No. 1 is now under the broach, which never leaves the stripper. Trip the press and bush No. 1 will be broached while bush No. 2 is pushed into the die plate.

With the ram up again, swing the lever back to the right and insert bush No. 3. Trip the press and bush No. 3 will enter the die plate causing bush No. 1 to be ejected below, while bush No. 2 will be broached. And so on.

An option has been obtained by a New York organization from the School Board, on a site on the north side of Bloor Street, at the head of Church Street, Toronto, and a ten-story private hotel will be built there. The cost is estimated at between $4,000,000 and $4,500,000.



SECTIONAL VIEW OF THE COMPLETE FIXTURE.



Development of 8 Driving Wheel Locomotive

By J. SNOWDEN BELL*

LOCOMOTIVES having eight driving wheels, the latest designs of which exemplify the most generally approved practice in heavy freight and passenger road service, the Mallet and Decapod types being adapted to, and ordinarily used only under exceptional conditions, were not, as a class, the outgrowth of increasing requirements in the operation of railroads, but were introduced at a very early period in their history, dating from some time prior to the year 1825. A review of the progressive steps of improvement that have brought them to their present perfected state will present features which have passed out of general recollection, and may, from a historical standpoint, be found of interest.

Wylam Colliery Railroad, 1825

The first eight driving wheel locomotives of which a record has been found, are those which are described and illustrated in Wood's "Practical Treatise on Railroads," London, 1825, as being then used on the Wylam Colliery Railroad, in England, and are shown in Fig. 1, which is reproduced from Plate VI of the Treatise. The boiler is of the return tube type, and, with the two vertical cylinders, is supported on a wooden frame, which is carried on two independent truck frames, these being fastened to the main frame "by bolts in the middle, which allow a lateral motion in the frames, to conform with the occurrence of curvatures in the line of the road."

Two pairs of driving wheels are fitted in each of the trucks. The piston rods are connected to beams, supported at one end on the main frame, from which connecting rods extend to cranks on the ends of a transverse shaft, located at about the middle of the length of the locomotive, which shaft carries a spur gear, engaging a similar gear on a shaft below it. The latter shaft is geared to the adjacent driving axle of each truck, and these to the other axles, intermediate gears being interposed to effect the rotation of all axles in the same direction, the locomotive thus having no less than eight spur gears for transmitting power from the pistons to the four driving axles.

The dimensions of the locomotives are not given, but from the scale accompanying Plate VI the cylinders appear to be about 8½ inches bore, for 24 inches stroke of pistons; the driving wheels 43 inches diameter; and the boiler 42 inches diameter and 9 feet 9 inches long. These locomotives probably weighed in the neighborhood of 10 tons, which was an extremely heavy weight at their date, and Nicholas Wood, the author of the Treatise, gives the reason for their distribution of weight as follows: (Pp. 155, 156.)

"The railroad on which these engines travel being too weak to support the weight divided on four wheels, recourse was obliged to be made to eight wheels; and this rendered the use of so many cog wheels necessary, to obtain the adhesion of the whole weight of the engine.

"This circumstance adds much to the complication of the engine, which, of course, increases the friction by the multiplicity of cog wheels and other moving parts."

Ross Winans, of Baltimore, Md., who will be remembered as one of the most prominent and successful locomotive builders of his time, obtained, on July 23, 1843, a patent of the United States, No. 3201, for "a new and improved manner of constructing locomotive engines with eight driving wheels," in the specification of which he states that:

"I do not pretend, therefore, to have originated the idea of constructing a locomotive engine with eight driving wheels, but limit my claim to invention to having so brought together, and combined, various known elementary parts of such engines as to have produced one

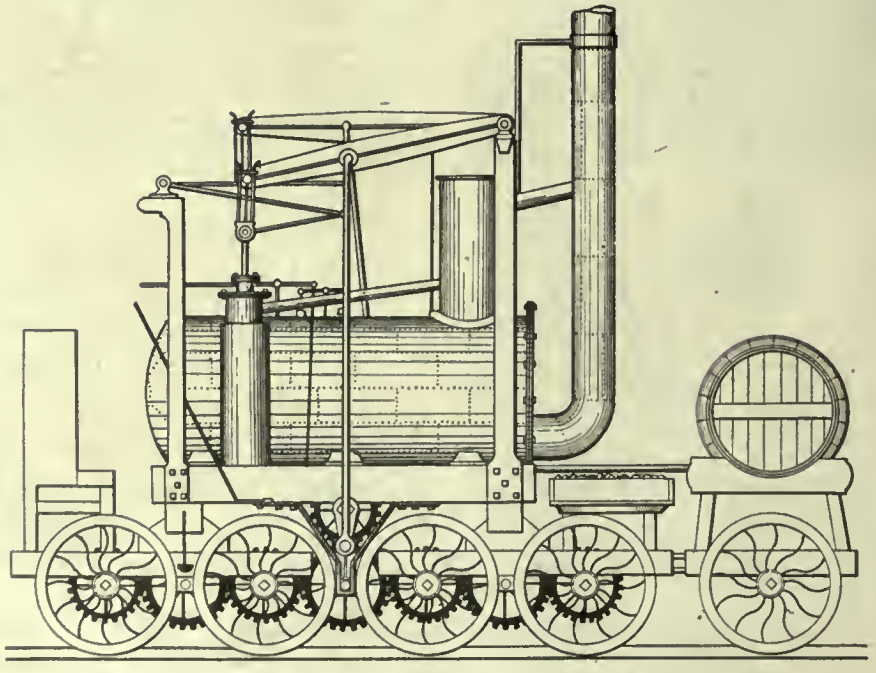


FIG. 1—AN EARLY TYPE OF EIGHT DRIVING WHEEL LOCOMOTIVE.

*From Record No. 189 of the Baldwin Locomotive Works.

which is substantially new, attaining the desired end in a manner more simple and effective than on any of the plans heretofore devised."

As shown in Fig. 2, which is reproduced from the drawing of the Winans' patent, the locomotive of that patent had a vertical boiler and horizontal cylinders, the pistons of which rotated a transverse spur wheel shaft at one end of the engine, which was geared to the nearest driving axle, with which the other three driving axles were coupled by end cranks and side rods. Two spur gears only were used, instead of eight as in the Wylam engines.

Three locomotives of this design were built to the order of Mr. Winans, by M. W. Baldwin, of Philadelphia, for the Western Railroad of Massachusetts, and were completed in April, May and June, 1842. No drawings of these engines are in existence, and it is believed that they were the only locomotives of this type that were built with vertical boilers.

Ross Winans, 1844

The "Report on the Use of Anthracite Coal in Locomotive Engines on the Reading Railroad," made by Geo. W. Whistler, Jr., April 20, 1849, states (p. 23) that "In October of that year, 1844, Ross Winans produced the first successful coal burning engine with a horizontal boiler," and the report further states that 12 of these engines were placed on the Baltimore & Ohio Railroad, between October, 1844, and December, 1846, and that a substantially similar engine was built by the company in May, 1847.

These engines, which were the first eight driving wheel engines on the Baltimore & Ohio Railroad, were known as the "mud diggers," doubtless by reason of their action on the then comparatively light superstructure of the road.

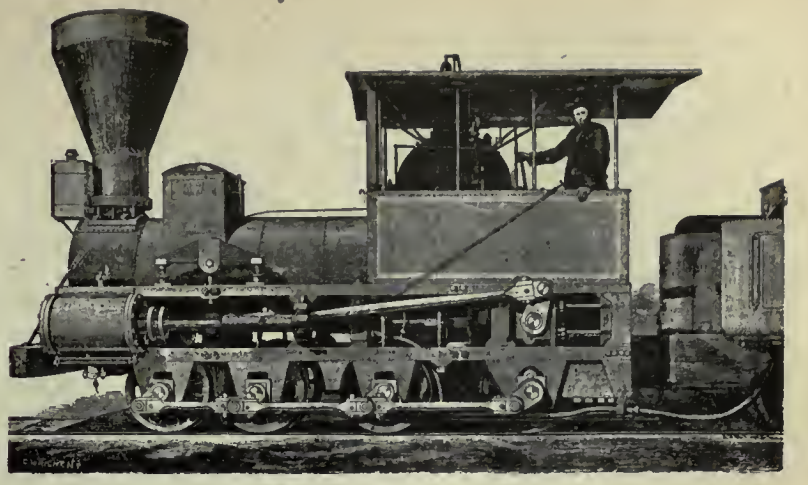

FIG. 3—THIS TYPE OF ENGINE WAS KNOWN AS A MUD DIGGER.

As shown in Fig. 3, which is reproduced from a photograph of engine No. 37, made at Mount Clare shops in 1863, the main connecting rods were, as in the three engines of the Western Railroad of Massachusetts before referred to, coupled to cranks on a shaft extending across the frames, in the rear of the boiler, and geared, by spur wheels, to the back driving axle. The four driving axles carried end cranks which were coupled by side rods.

The 12 Winans' engines of the Baltimore & Ohio Railroad, mentioned in Mr. Whistler's report, were of the above construction, and were the "Hercules," No. 33, October, 1844; "Gladiator," No. 34, November, 1844; "Buffalo," No. 35, November, 1844; "Baltimore," No. 36, December, 1844; "Cumberland," No. 37, July, 1845; "Elephant," No. 38, July, 1845; "Opequan," No. 40, July, 1846 "Elk," No. 41, August, 1846; "Catoctin," No. 42, October 1846; "Youghiogheny," No. 43, November, 1846; "Tuscarora," No. 45, December, 1846, and "Allegheny," No. 46, December, 1846. The engine built by the company was the "Mount Clare," No. 49, May, 1847.

These engines weighed 23.5 tons. and had 17 x 24-inch cylinders and 33-inch driving wheels. Some of them were in yard service as late as 1865, and probably for some years afterwards. A number of their cylinders and main connections were used as parts of stationary engines in the shops of the road after their road service was terminated.

M. W. Baldwin, 1846

The first locomotives, of what is now known as the 0-8-0 type, in which the objectionable feature of gearing was eliminated, by coupling the main con

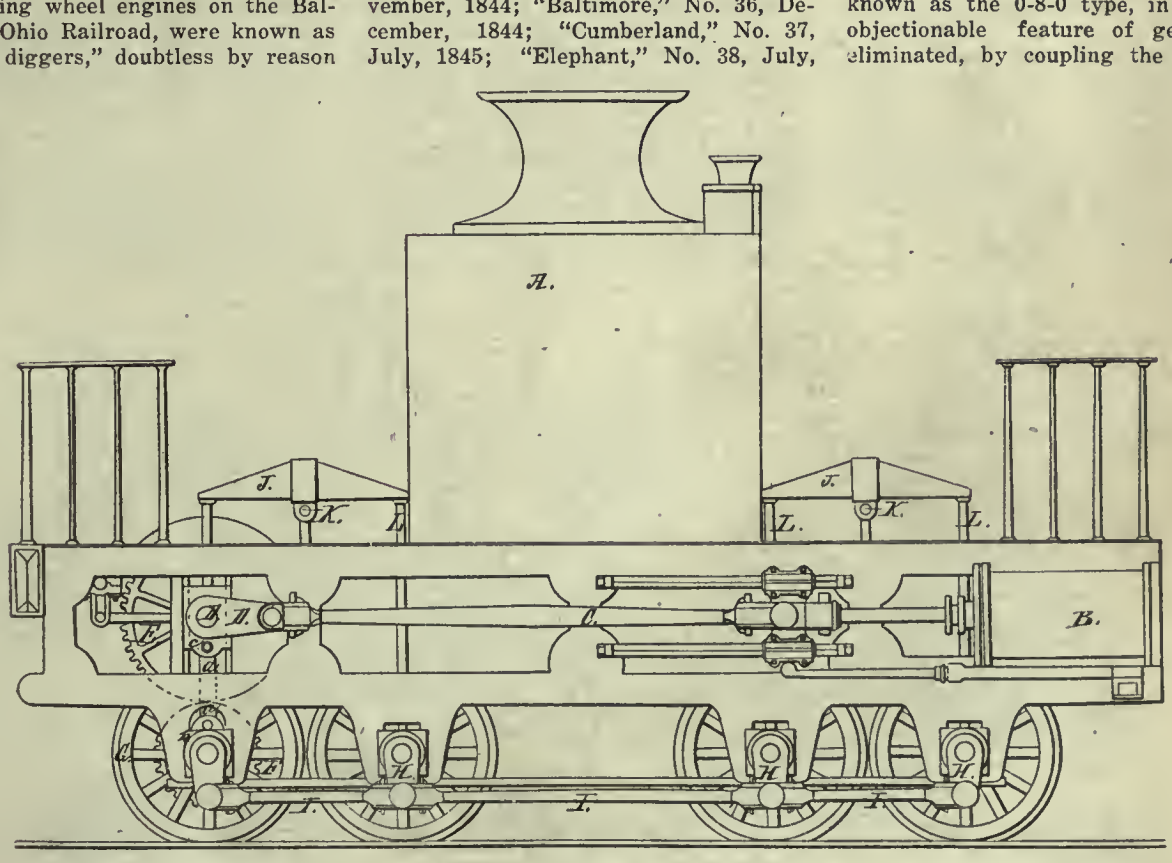

FIG. 2—A REPRODUCTION OF THE WINANS' PATENT.

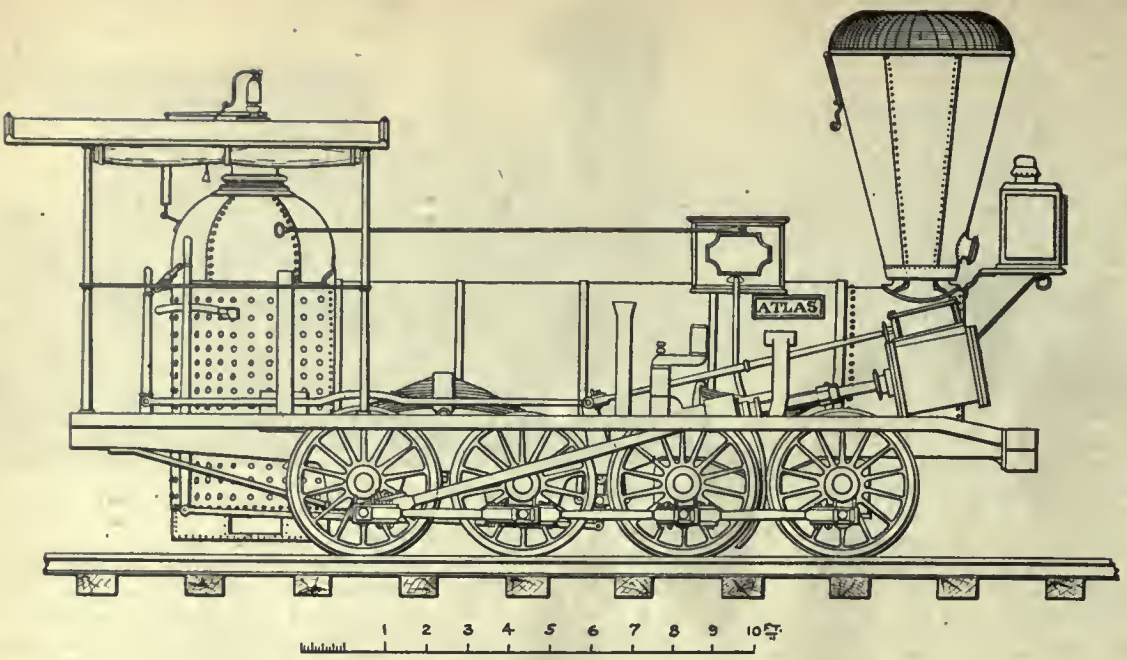

FIG. 4—SHOWING INCLINED CYLINDERS AND DROP HOOK VALVE GEAR.

necting rods directly to the crank pins of the main driving axle, were built by M. W. Baldwin, seventeen of them being constructed in a single order, for the Philadelphia & Reading Railroad, in 1846. Two of these engines, the "Atlas" and the "Hercules" (Fig. 4), which were used in pushing service on the Falls grade, at Philadelphia, weighed 27 tons, and their cylinders were 17¼ x 18 inches and driving wheels 42 inches in diameter. The other engines of the order weighed 22.4 tons, and their cylinders were 15½ x 20 inches, and driving wheels 46 inches in diameter.

The characteristic feature of all of these engines was the very ingenious appliance known as the Baldwin "flexible beam truck," in which the boxes of the first and second axles were fitted in beams, which were articulated independently, to the main frames on opposite sides of the locomotive, by spherical joints. The driving boxes were turned cylindrically and fitted in correspondingly bored pedestals, and the brasses of the front coupling rods were cylindrical and fitted on corresponding pins. The wheels of the third axle had flat or "blind" tires. The engines were thus enabled to pass curves of very short radius. The flexible beam truck is the subject of Mr. Baldwin's patent No. 2759, of August 25, 1842, and the principle of its operation is well and clearly stated by Zerah Colburn, in his treatise "Locomotive Engineering," 1871, p. 85.

All the engines of the first order had inclined cylinders and drop hook valve gear, as shown in Fig. 4. The 15 lighter engines were also fitted with independent cut-off valves, but single main slide valves were applied on the "Atlas" and "Hercules." The fireboxes of the latter engines were small, having only about 8.45 square feet of area and the engines burned wood fuel. The total heating surface was about 1153 square feet, and, on the basis of the evaporative value of the tubes and firebox, the boiler power appears to be in excess of the cylinder requirements. The tractive power of the engines may be estimated at about 10,850 pounds, and it is probable that no engines of greater power had, up to their date, been built. They did efficient service for many years, and a number of them were rebuilt by the railroad company, with wide fireboxes for anthracite fuel, and link motion valve gear.

The general design of the Reading engines continued to be the practice of the Baldwin works, in the 0-8-0 type, until that type was superseded by the addition of a leading truck. In some instances, as in wood burning engines, the firebox was located between the third and fourth axles, instead of behind the rear axle, and the final modification of the design, which was made some time prior to 1854, provided an increase of

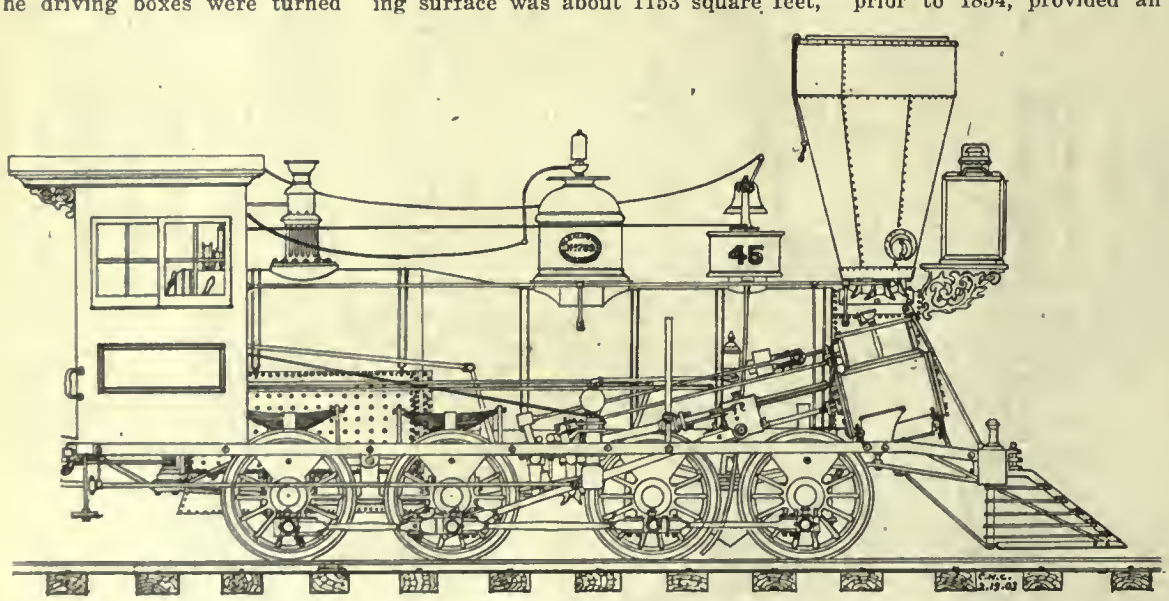

FIG. 5—THIS TYPE WAS BUILT IN 1857.

grate area and firebox surface, by setting the firebox on top of the rear axle. A number of locomotives of this construction were built for various railroads, one of which, No. 45 of the Pennsylvania R.R., built in 1857 is shown in Fig. 5. This engine had 18 x 20-inch cylinders, 42-inch driving wheels, and weighed 63,700 pounds.

Ross Winans, "Camel," 1848

As has been stated by Zerah Colburn, whose eminence as an authority on locomotive engineering is beyond question, the so-called "camel" engine of Ross Winans was, "as a whole, the most peculiar engine in use in the United States. In every detail of construction this engine is alike peculiar, and in the strongest possible contrast with the proportions, arrangement and workmanship of the standard American engine." Its design is quite clearly shown in Fig. 6, which is reproduced from an advertising lithograph issued by Mr. Winans.

The distinctive features of novelty of the camel engines were the following: 1. The use of eight driving wheels, set closely between horizontal cylinders and a long overhung firebox, the width of which was equal to, or greater than, the distance over frames. 2. A firebox having a downwardly and rearwardly inclined top, which was exclusively a water casing, there being no steam room in it. 3. A dome and engineer's cab, placed on the top of the boiler, close to the forward end. 4. An upper chute or pair of chutes, for feeding coal through the top of the firebox. 5. A firebox having no water space on its rear side, which was closed by doors, so as to expose its entire area when desired. 6. The abandonment of crown sheet stay bars, and the substitution of stay bolts connecting the crown sheet with the outer shell. 7. The use of a half stroke cam, as a means for effecting cut off. All these engines were substantially of the same construction, except as to the firebox, of which there were three classes, the short, the medium and the long.

The first engine of the class, the "Camel," No. 55, was placed on the Baltimore & Ohio Railroad in June, 1848, and 112 in all were comprised in the company's equipment. A number were also built for the Philadelphia & Reading, Pennsylvania, Northern Central, Delaware, Lackawanna & Western, and other railroads. Some of them were rebuilt and modified, and many remained in yard service for a long time after more modern equipment took their place in road work.

Ross Winans, "Centipede," 4-8-0 Type, 1856

The first locomotive in which eight driving wheels were combined with a four-wheeled leading truck, and what is now known as the "Mastodon" or 4-8-0 type, was the "Centipede," which was built by Ross Winans in 1856, and sold to the Baltimore & Ohio Railroad in 1863. This engine is of special interest, not merely as being the first of its type, but also by reason of numerous novel and peculiar features of structure which it embodied, and it is greatly to be regretted that no description or drawings of it appear to have been preserved, and, therefore, that it can be described only from the recollection, naturally dimmed by the lapse of years, of the few now living who, like the writer, have seen the engine.

The boiler was of the same form, and about the same size, as those of the camel engines; the cylinders were 22 inches bore and 22 inches stroke; and the driving wheels 43 inches in diameter. The weight was probably not far from 29 tons. The engine had independent cut-off valves, and the cab was located on the front bumper platform, the throttle rod passing through the stack. The bearings of the truck axles extended nearly the entire length between the wheels, and there were other peculiar details which cannot now be remembered.

Comparatively few locomotives of the 4-8-0 type have been built for American railways. Probably the most extensive user of this type is the Norfolk & Western, which in the years 1906 and 1907, placed in service 100 4-8-0 type engines built by The Baldwin Locomotive Works. These were followed, in 1910, by 50 heavier engines of the same type. One of the latter is illustrated by Fig. 7.

These locomotives, as originally built, used saturated steam, and were equipped with Walschaerts valve motion and piston valves. They were of the following dimensions:—weight of engine, 261,100 pounds; weight on driving wheels, 213,200 pounds; cylinders, 24 x 30 inches; driving wheels, 56 inches diameter; boiler, 80 inches diameter; heating surface, 4041 square feet; grate area, 44.7 square feet; boiler pressure, 200 pounds; factor of adhesion, 4.07; maximum tractive power, 52,500 pounds.

Baltimore & Ohio R.R. Co., 1865

With a view to the avoidance of certain structural objections which obtained in the camel engines, as well as to incorporate additional features of improvement, Thatcher Perkins, then master of machinery of the Baltimore & Ohio Railroad, designed a class of locomotives of the 0-8-0 type, which were variously termed the "Perkins' eight

wheel connected engines," the "green backs," and the "Jerseys." These engines are shown in Fig. 8, and 24 of them were built in 1865, two by the company, two by Reaney, Son & Archbold, of Chester, Pa., and 20 by the Grant Locomotive Works, of Paterson, N.J.

The Perkins 0-8-0 engines were similar to the "camels" which they were intended to supersede, only in the particulars of having overhung fireboxes, of the full width over frames, and 43-inch driving wheels, and differed therefrom in the following particulars. Their boilers were larger, being of the straight type, of ⅜-inch iron, 48 and 48¾ inches diameter at alternate rings. Their cylinders were bolted to an intermediate bed or saddle, on which a round smoke box was supported as in present practice, and were originally bored out to 19½ inches, but were designed to be rebored to 20 inches, being 1¼ inches thick.

Their frames, which were of the bar type, were very substantial, weighing about one ton apiece, and having top rails finished to 3¾ x 6 inches. The link motion was of the Gooch type, and a radius of 55 inches was obtained for the links by connections to and from a supplemental rocker shaft. The links were of cast iron, of box form, and weighed 434 pounds each. The draw bar extended through the ash pan, and its front end was coupled to a pin fitted in cross braces bolted to the bottom frame rails. This arrangement, by which the boiler was entirely relieved from strains of draft and buffing, was applied by Mr. Perkins at a much earlier date, and it has, within a few years past, been brought out as a new and original design.

The principal particulars of these engines were as follows: Weight, 65,000 pounds (empty); cylinders, 19½ x 22 inches; boiler, larger diameter, 48¾ inches; thickness, ⅜ inch; pressure, 100 to 110 pounds; 115 flues, No. 12 W. G. 2½ inches outside diameter and 15 feet long; inside firebox, length, 66 inches; width, 42 inches; depth, 57 inches; grate area,, 19.25 square feet; flue-sheet (copper), ⅝ inch; back sheet (copper), ⅜ inch; side sheets (copper for 36½ inches from bottom 3-8 inch; exhaust nozzle (single), 4½ inches. Weight of tender, 23,000 pounds; water capacity, 2140 gallons.

Yard Engines of 0-8-0 Type

The earlier engines of this type were usually relegated to maintenance of way and yard work, when, as they became old, they were replaced by heavier power in road service; but within the last few years engines of this type, of weight and power greatly exceeding the earlier road engines, have been designed for, and advantageously operated in, yard service, where comparatively heavy loads were required to be moved.

Fig. 9 shows an engine of this class, built in June, 1917, by The Baldwin Locomotive Works, for the Duluth, Missabe and Northern Ry., which embodies the latest and most improved practice in the 0-8-0 type, and is also very much larger and more powerful than the average road engine of that type which preceded it.

The weight of this locomotive is 216,000 pounds; cylinders, 24 x 28 inches; driving wheels, 51 inches diameter; heating surface, 2690 square feet; superheater surface, 621 square feet; grate area, 48.2 square feet. The boiler pres-

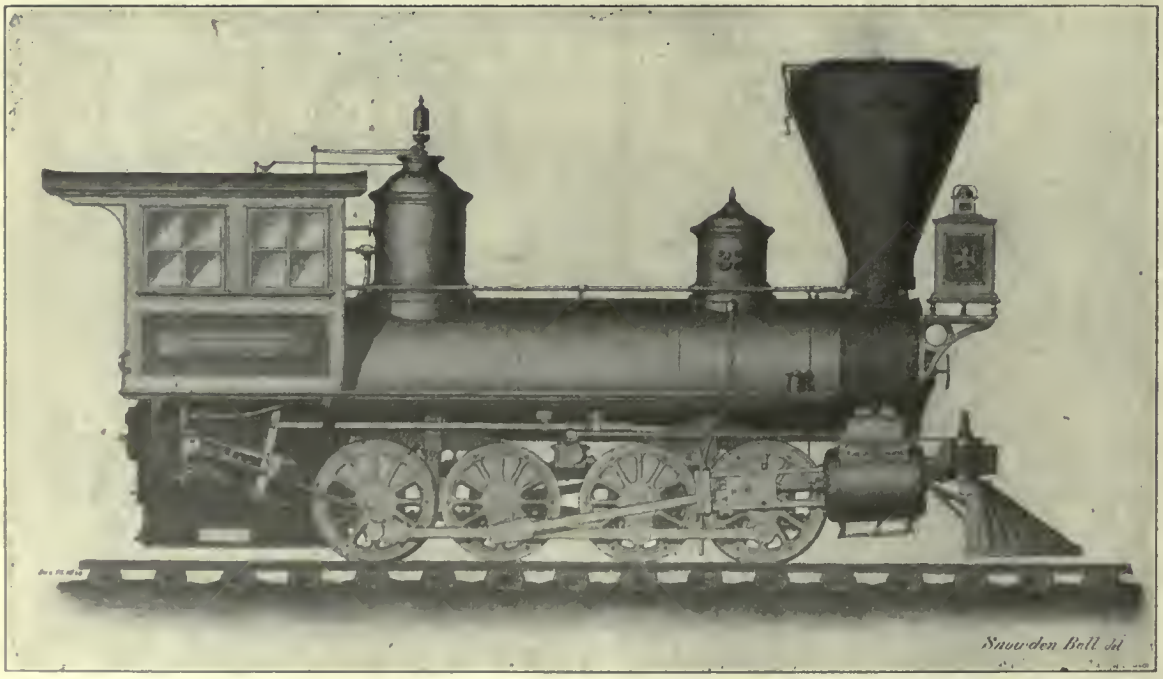

FIG. 8—SHOWING THE PERKINS EIGHT-WHEEL CONNECTED ENGINE.

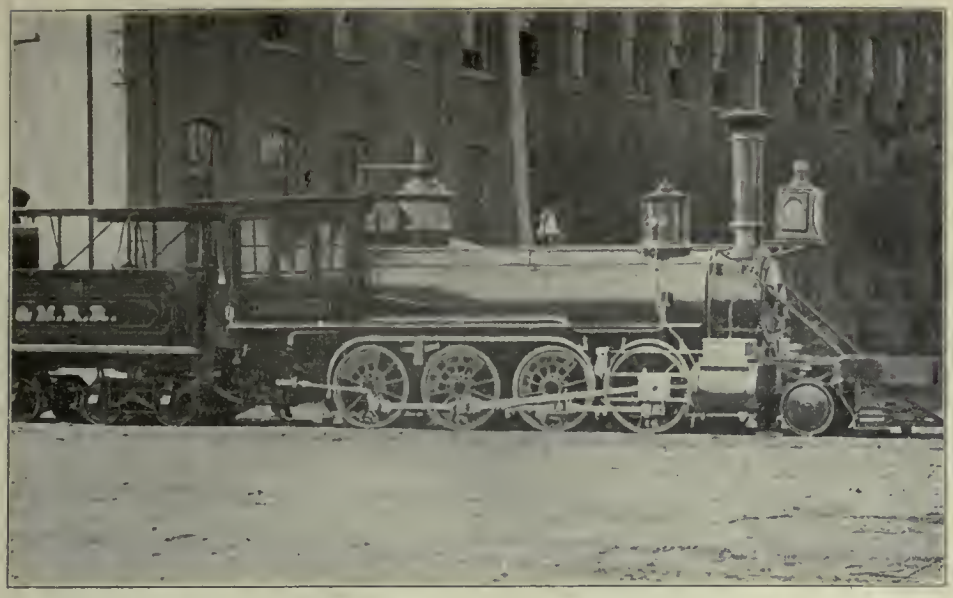

FIG. 11—REFERENCE TO THE TEXT WILL GIVE DETAILS REGARDING THIS P.R.R. TYPE.

sure is 185 pounds; maximum tractive effort, 49,700 pounds, and factor of adhesion, 4.35.

J. P. Laird, 2-8-0 Type, 1864

The next, and most generally adopted, step in the design of the eight driving wheel locomotive, consisted in the application of a two-wheeled leading truck, thereby providing the 2-8-0 (usually termed the "Consolidation") type. This was originated by John P. Laird, then master of machinery of the Pennsylvania R.R., who, in 1864, rebuilt the Baldwin engine No. 98, which was originally of similar construction to engine No. 45 (shown in Fig. 5) and among other changes, put in a two-wheeled leading truck.

As shown in Fig. 10, the rebuild also included an increase of the driving wheel base, and the addition of side tanks and a rear coal bunker; also the fitting of all the driving axles on pedestals rigid with the main frame. The rebuilt engine 98 was used in pusher service on the Allegheny Mountain grade, and in the latter part of 1864 or early part of 1865, another Baldwin engine, No. 97, which was originally similar to No. 45, was rebuilt on the same lines as No. 98.

A. Mitchell, "Consolidation," 1866

In July, 1866, the Baldwin works built to the order of Alexander Mitchell, master mechanic of the Mahanoy division of the Lehigh Valley R.R., the 2-8-0 type locomotive "Consolidation," which has been usually believed to be the first of that type; and prior to the adoption of the present system of classification by wheel arrangement, the type was known by the name of this engine. It was however, as above stated, originated two years previously by John P. Laird, his first locomotive of that type (P.R.R. No. 98) differing from the "Consolidation" in being a tank engine for pusher service, while the latter was a road engine with tender, as shown in Fig. 11.

The weight of the "Consolidation" was 90,000 pounds, of which 80,000 pounds was on the driving wheels; cylinders, 20 x 24 inches; and driving wheels, 48 inches diameter. The design soon became practically the standard for heavy freight service, and up to the present time continues to be generally approved practice, under ordinary conditions.

A NEW BRITISH UNDER-WATER PUMP

In salvage operations, in well-making, and in many kinds of dock and harbour engineering great advantage is gained by using a pump which can work under water. Several types of submersible electric pumps have been designed by British engineers, and the latest type has some special features of interest. The usual practice is to allow the water free access to the stationary part of the motor, thick rubber being used to insulate the electric circuits. In the new invention this part of the motor is cased in a special steel alloy, the casing being filled with oil. This arrangement makes the motor very compact and of high efficiency. By using suitable materials for the casing and pump parts, and a special incorrodible steel alloy in the rotating part of the motor, the pump can be adapted for handling weak acids and other corrosive liquids.

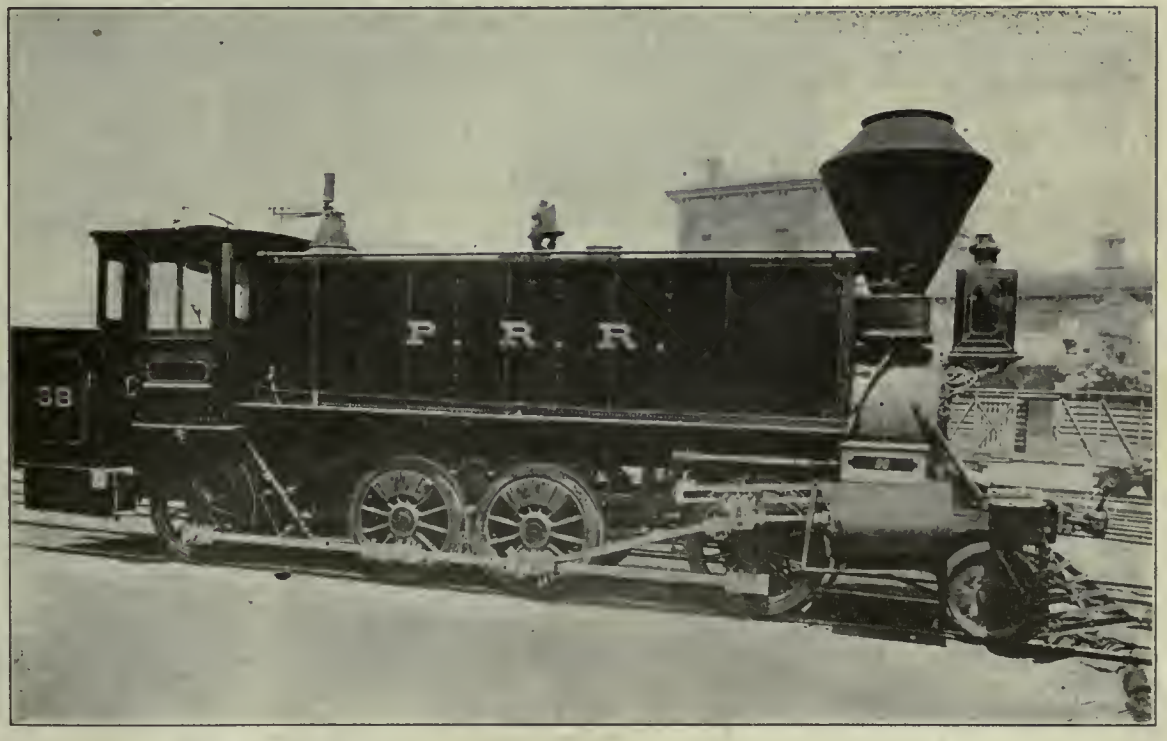

FIG. 10—NOTE THE INCREASED DRIVING WHEEL BASE, AND ADDITION OF OTHER PARTS

Heat Losses in Operation of Electric Furnaces

The Chief Causes of Heat Losses in Electric Furnace Operation Are Described—Various Experiments Were Made to Eliminate These Losses and the Results of Same Are Stated Herein.

By F. HODSON, President Electric Furnace Construction Co.

SOME very interesting data were recently presented before the American Electrical Society, by M. R. Wolfe and V. de Wysocki on the heat losses through electrodes on a 3-electrode 6-ton furnace. The figures given to follow will no doubt surprise many electric furnace users as to the amount and cost of power they are losing through the furnace roof. After a close study of this particular problem for the last four years, the writer is only surprised that the losses recorded were not larger. If the amount of heat in the shape of flame that escapes from most furnace roofs were taken fully into account, the loss would be found to be nearer 30 than 18.7 per cent. The method employed by the authors of the data we referred to above, whilst giving actual heat losses from the electrodes, only gives heat absorbed by the water cooler—a great deal more than this is usually lost.

In considering these heat losses, which perhaps would be better described as through the furnace roof rather than through the electrodes, it might be interesting to consider how the conditions governing the loss of heat and power can be improved.

The Causes

Broadly speaking, the causes are: (1) Heating up of electrodes, due to faulty electrode joint or defective electrode; (2) Heating up of electrode due to imperfect contact or badly designed electrode holders; (3) Heating up of electrode, due to electrode pencilling off at point of arc; (4) Heating up of electrode due to oxygen from the air combining with the carbon of electrode and burning off.

Special care should always be taken in jointing up electrodes—troubles due to this become increasingly worse as the melt proceeds. Good quality electrodes can now be purchased, and it pays to pay even a little higher price for proved electrodes. The design of electrode holder should be carefully considered and changed if undue losses occur. With proper contact, little or no heating should occur here; on our own furnaces we have not found it necessary to install water-cooled holders, looking upon these as an admission of failure to get proper electrical contact.

Pencilling of Electrodes

This is probably the indirect cause of more heat losses than any other feature. It is accentuated in cases where too large a space is left between the electrodes and the cooling ring, or where the furnace doors are not kept properly closed at the bottom or where, as in some cases, the melter has to unduly open his doors to inspect or rabble his molten charge. The air strikes the white-hot electrode and burns away carbon, the hole in the roof acting as a flue draft, and the electrode pencils off, so that the area at the bottom, where the arc is, is often only one-fifth of what the furnace builders have designed to carry the power behind the furnace. The current continues to flow through this restricted area of electrode and its resistance to the excessive current over the smaller area results in the whole electrode heating up instead of going into the arc. This also causes trouble with the joints, with the holders, and on all the outside electrical connections. Sometimes large pieces or flakes of electrodes break off, due to the increased resistance.

With the above facts in mind, our metallurgists have been working for the last five years to try and prevent this pencilling and heating up of electrodes. It was realized early in the investigation that if the flame could be prevented from blazing out at the top that one of the chief causes, viz., pencilling, would be largely overcome. Experiments have been made with over a dozen different types of water cooler and also attempts were made to insert an inert gas under the furnace roof.

As a result of these experiments, Mr. F. W. Brooke, vice-president of our company, has developed a type of electrode cooling ring or electrode economizer, now fitted as standard on all Greaves-Etchells furnaces, that really does prevent this flame and consequent pencil-

(Continued on page 95)

FIG. 1——VIEW OF FURNACE IN OPERATION.

Would You Like to Receive One of These Scales FREE?

You can easily do so and at the same time add to your store of knowledge by entering our weekly contest of which details are given below.

The scale is 6 in. long and is made from finest quality steel. One side is marked in 32nds, the other side in 64ths. A table of decimal equivalents is also stamped on one side, and a table of tap drill sizes on the reverse side. This scale is well worth securing.

What You Have to Do

We publish every week a number of interesting facts or statements selected from the advertising pages for that week. The selections for this issue are given below. Read these through, then turn to the advertising section and see if you can pick out the advertisements to which they refer. The work is interesting, it will train your powers of perception and of memory, it costs you nothing, it will make you better acquainted with the various lines of machinery and tools in the market, and with perseverance you are bound to win one of these useful scales as a prize.

Contest for December 2nd Issue

Contestants are required to write us stating to which advertisements in the advertising section in this number the following references are made:

1. Where to get valuable advice.
2. How to figure the net value of a reamer.
3. Something that can be used with confidence.
4. A material that is said to be ideal for use in the construction of heavy duty machinery.
5. A machine said to be quick and easy of control.
6. Something said to have enormous gripping power.
7. Something that will take larger work and turn out larger production.
8. How to secure something that is erasure proof.
9. How to perform long drilling operations.
10. Something that is said to have a powerful positive drive
11. A product that has been manufactured constantly for 60 years.
12. Something said to be highly endorsed.

Closing Date for This Contest is December 23rd

WELDING AND CUTTING

The Welding of Wrought Iron and Steel

The Equipment and Materials Necessary, the Preparation of the Weld, the Use of the Carbon Electrode and Other Points Are Described

By H. L. UNLAND

THE welding of wrought iron and steel in simple sections by the electric arc welding process presents no serious difficulties. Reasonable care on the part of the operator in keeping the weld clean and in the preparation of the weld will, with ordinary skill in welding, result in a successful weld.

The subject of welding may be divided into three steps:

1. Equipment and materials.
2. Preparation of weld.
3. Welding.

Equipment and Materials

In addition to the equipment and auxiliary apparatus, special jobs render it desirable to have on hand other miscellaneous pieces of equipment.

Odd pieces of carbon block or of copper are of much assistance as dams in holding the molten metal in place. In cases where the weld must be smooth on one side, a piece of copper or carbon is held against the weld and metal filled against it. Iron or steel can be used if care is taken not to weld to it.

In filling a hole the bottom is often closed by holding a plate of carbon or copper against it until sufficient metal is filled in to hold.

Care should be taken to flow the molten metal against the guide pieces and not to allow the arc to play directly on them, otherwise the weld will probably be contaminated by this material, or else the guide piece may be welded solid and cannot be easily removed.

A steel wire scratch brush is used to remove light scale and rust, before commencing to weld if necessary, and also at intervals during the welding, usually when changing electrodes.

For small work the positive lead may be bolted to an iron plate forming the top of a work bench. The work may be set on this bench, the contact being sufficient to carry the current. In many cases a vise mounted on the table will be found desirable. If the work is too large for the table it may be set beside the table and a bar laid across to it. This will provide sufficient current-carrying capacity, provided scale and rust do not entirely prevent contact. The rails in a round house, if bonded, are usually connected to the positive lead, and any car on these tracks may be welded by running only the cable leading to the electrode, the return cable being unnecessary since the current will be carried back through the rails.

A convenient terminal for the positive cable consists of a copper hook of proper size to which the cable is bolted. The terminal may be laid on the work or hooked on a projecting part. It is seldom necessary to actually clamp the return lead to the work unless the metal is thickly covered with scale or dirt, which acts as insulation, in which case it is easier to chip or brush off a clean place for the contact than to use a clamp.

The author of this material occupies a position in the Power and Mining Engineering Department of the General Electric Co., and is well able to speak on the subject. He emphasizes the importance of keeping the work clean, and describes various methods of cleaning the same.

If welding is to be done in a room where other employees are doing other work, screens should be provided around the welding operator. They should be high enough to prevent the light striking a large part of the ceiling since the flicker of this light would probably affect the other workmen. The effect, while probably not injurious, would be irritating. White walls and ceiling should be avoided in a welding room.

Gas burners for preheating, and fire brick, sand, or sheet asbestos for covering, are useful, especially for cast-iron work, which in many cases should be preheated uniformly to a red heat and welded while at this temperature. A receptacle of water is desirable, in which the electrode holder can be cooled when it becomes too hot after continued use.

Some operators feel that gloves are necessary to protect the hands from the arc. In many cases, however, operators find gloves to be in the way, especially when working with the metallic electrode. If desired, however, any leather or cloth glove will give sufficient protection to the skin of the hands which is much less sensitive than the skin on other parts of the body. The arms, neck, and face should, however, be covered, since exposure of these parts will probably result in burns similar to sunburn, which, while painful, are not serious.

The Flux

It is the experience of a great majority of welders that flux of any kind is unnecessary in welding, and further, that it is a source of danger in that there is liability of contaminating the weld. If the work is kept clean by brushing at frequent intervals and ordinary care is taken in the operation of the arc a good weld can be made without flux and if these attentions are lacking, flux will not make a good weld.

Preparation of Weld

Metal that is clean is much more likely to make a good, strong weld. Scale, rust, grease, soot, and foreign matter will contaminate the weld and such inclusions necessarily weaken it or else make it hard. Impurities may also make the metal porous and spongy, due to liberation of gas. Pieces of foreign matter may prevent the molten metal filling all parts of the weld and cause cavities.

Various methods for cleaning are in use—pickling for small parts, washing with gasoline or lye, boiling with lye, sand blasting, chiseling, scratch brush, ing etc., the method depending on the local conditions.

Preparatory to welding locomotive tubes to the sheets, it is sometimes advantageous to send the locomotive out on a run to burn off the grease and then clean off the oxide and soot by sand blast. Another method is to heat the boiler to normal by steam pressure and then clean by sand blasting or scratch brushing.

In welding heavy sections where it is necessary to deposit several layers of metal, the surface of the preceding layer should always be cleaned before starting the next.

For long seams the edges should be ⅛ inch apart at the end where the weld is started, and at the far end the space should be ⅛ inch plus 1½ per cent. of

the length. This takes care of the expansion of the metal in the sheet and also of the contraction of the metal in the weld as it cools.

Another method of reducing expansion is to put in short sections at intervals, welding in one layer at a time, starting at the centre and working alternately toward either end. Then put one layer in the open sections, and continue in the same way till the weld is completed. The welded section of any layer should not match those in the layer below or above, the joints being broken as in laying brick work.

The welding of complicated shapes such as flywheels and some castings may require preheating at certain points to produce initial expansion which will be overcome as the weld cools. In some cases the entire piece must be preheated and in some cases after welding the whole piece must be annealed. This is sometimes done by heating the piece uniformly and then covering it with sand-asbestos, etc., and allowing it to cool slowly.

In welding cracks in plates, forgings, or castings the crack should be chiseled out to get a good bevel entirely through the plate with ⅛ to 3-16 in. clear opening on the back or to the bottom of the crack in castings or forgings. In boiler work ½ inch holes are sometimes drilled well beyond the ends of the crack and the crack chiseled, beveled, and welded.

Welding With the Metallic Electrode

The arc should be kept short, not over ⅛ inch in length.

The current should not be greater than those indicated in the table for the electrode diameter. Excessive current causes burnt or porous metal to be deposited.

The arc should be kept constant in length to insure uniformity in the metal deposited.

In welding a seam the electrode should be moved in a zig-zag or circular path advancing along the seam. The metal will adhere only to the surface of the work actually played on by the arc so care must be used to bring the arc in contact with the whole surface to be welded.

Be sure the electrode is connected to the negative terminal. If the polarity is reversed the arc will be more difficult to maintain and the deposited metal will not be as good as it should be.

In starting the arc the electrode should be just touched to the work and withdrawn immediately to the required distance. If the electrode is held too long in contact it will weld to the work, causing some delay in freeing it and starting over.

In welding be sure that the arc plays over the entire surface of the joint. The metal of the work is fused by the direct impact of the arc and if molten metal merely runs ahead of the arc over the solid metal of the work, it will not result in a weld.

The metallic electrode used is generally from 14 to 18 inches long. It may be gripped in the holder, either at one end or in the middle as required by the skill of the operator or the nature of the work.

The operation of welding overhead is the same as in normal welding. The difficulty largely lies in holding the electrode steady in the cramped position usually required. If the arc length is kept constantly short the metal will be successfully deposited, and practice is required to accomplish this. The appearance of an overhead weld is sometimes marred by drops of metal projecting or by uneven thickness of the deposited metal, but this can be overcome by proper manipulation of the electrode. A rest for the arm will sometimes assist the operator to hold the electrode steady.

Use of the Carbon Electrode

The holder should grip the electrode from 4 to 5 inches from the end. The electrode should for ordinary work be tapered to a blunt point at the working end to keep the arc from wandering over the end of the electrode. As the electrode burns away with use, the holder is moved back along the electrode to keep length of working carbon constant. The burning away of the electrode will tend to keep the taper approximately constant.

The arc is struck in the same manner as with the metallic electrode, but a longer arc should be used, from 1 to 1½ inches is the average. The arc should not be too short when welding or depositing metal as there is danger of depositing carbon in the weld with the probability of a hard weld resulting. In cutting or melting off metal, the arc should be kept short, about ½ inch being an average length.

To cut (for which purpose the carbon electrode must be used) the arc is operated like a gas torch. It is held in one place long enough to fuse the metal and allow it to run off. For thin plates laid flat a hole is melted through by holding the arc on one spot, then the electrode is slowly advanced along the desired line, the molten metal dropping out below. For thick pieces, such as shafts, castings, etc., it is desirable to start at the top on one edge and work down, allowing the molten metal to run down through the cut. It is often necessary to follow the molten metal down with the arc to keep it melted until it runs off.

The width of the cut will depend on the size of the electrode used and on the skill of the operator in keeping to a straight line. The cut will be slightly wider than the diameter of the electrode in order to allow the arc to be played on the bottom of the cut, and it will be wider for thick sections than for thin ones. The edges of the cut will not be smooth, due to the masses of the molten metal not running away and also to the fact that the arc will tend to jump from one point to another and cause an uneven cut.

To deposit metal with the carbon electrode, the arc is struck as above, but is not held in one place long enough to melt through. A pool of molten metal is established and a melting rod of metal is fed into the arc and melted down on the work. It should all be heated thoroughly to insure complete union before more metal is added.

Since heavier current can be used with the carbon electrode than with the metallic, faster work can be done in depositing metal. The quality of the weld is not quite so good, however, as when the metallic electrode is used. However, for filling holes in castings, building up worn spots, etc., the carbon weld is satisfactory and should be used.

Due to the high temperature and large amounts of heat liberated when using the carbon electrode, the electrode holder is liable to become very hot and under some conditions to melt away at the end. When the holder begins to get hot it should be plunged in a receptacle of water kept conveniently near the operator.

Cutting speed with the carbon electrode for various values of currents strengths and thicknesses of material will be approximately in accordance with the curves shown in Fig.

Cast Iron Welding

This metal, due to its properties, is unsatisfactory for welding by any method. Its low strength and brittleness causes it to break from expansion and contraction strains unless precautions are taken, and even then a successful weld cannot be assured.

Pieces of simple cross section and heavy pieces present much less difficulty than complicated shapes, but due to the undependable nature of cast iron care should be used in all cases.

The experience and skill of the operator are large factors in determining whether or not a given weld will be successful.

By experimenting, a number of operators have learned to weld copper to copper, copper to brass and steel, and bronze to bronze, as well as Monel metal, high-speed steel and Stellite. The special uses are rather limited in their application and the methods vary, so it is recommended that each operator experiment along the lines suggested by his experience.

Steel Plant in B. C.—Incorporation of the Coast Range Steel, Limited, with a capital of $15,000,000 and controlled by British capital, was announced at Vancouver. It is the intention of the company to create an iron and steel plant with blast furnaces on the lower mainland of British Columbia. Plans of the company provide for the ultimate expenditure of $50,000,000 in the establishment of a great iron and steel industry, and it is the intention to start active construction within six months. Engineers have been in the province for two months making a survey of the situation. Vancouver men named directors are H. J. Landahl, Fred T. Congdon, J. D. Kearns, John Steta and Major Montague Moore. The provincial government has approved the project and will pay a bounty per ton on pig iron production.

DEVELOPMENTS IN SHOP EQUIPMENT

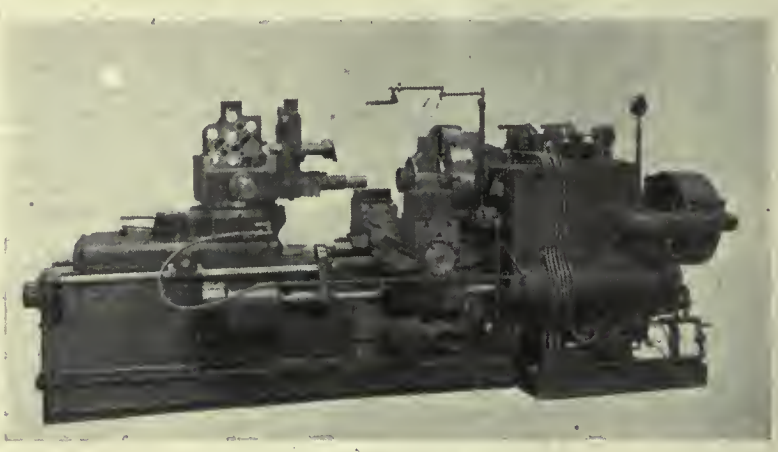
AUTOMATIC CHUCKING AND TURNING MACHINE

A new automatic chucking and turning machine, termed the 8B, has been developed by the Potter & Johnston Machine Company, Pawtucket, R.I. This machine is built with a geared automatic change speed head, and the spindle-driving mechanism is all contained in the headstock, which is of unit construction. The machines are heavy, powerful, and accurate, well suited to the manufacturing of multiple parts. The drive is by a single pulley transmitting 20 h.p.

Four combinations of six automatic variations of speed are available, giving twenty-four spindle speeds in geometric progression from 6 r.p.m. to 92.5 r.p.m. Any one of these combinations may be instantly obtained by levers conveniently located on the headstock. The gearing for driving the spindle is self-contained within the headstock, all gears running in oil, which is pumped through all bearings. A gear on the spindle takes care of the higher spindle speeds, while the lower ones are taken care of by a gear fastened to the chuck or faceplate.

The feed gearing is driven from the spindle. There are seven combinations of three automatic variations of feed, making a total of 21 feeds from .005 in. to .125 in. per revolution of the spindle. By changing one train of gears conveniently located on the outside of the machine the range of feeds may be doubled. The hand changes for the feeds are obtained by means of tumbler levers, conveniently located at the front of the machine. The ratio of the second feed to the first feed is constant. The third feed is independent of the first two and any desired combination may be obtained. The changes obtainable on the machine give the proper lead for cutting from twenty to four threads per inch, using automatic collapsing taps or automatic opening die heads. Any one of the three feeds can be obtained automatically at any time. The feeds are independent of the high constant speed for idle movements of the turret slide while withdrawing, revolving and advancing the tools to the point of cutting.

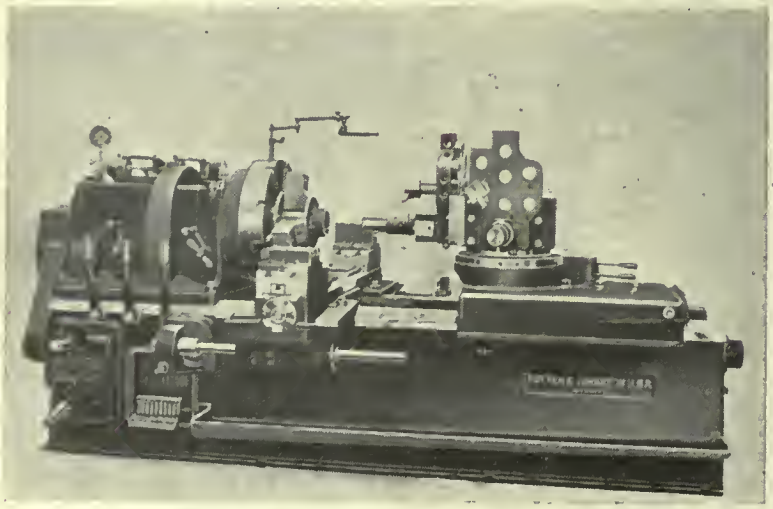
The cross slide is provided with front and rear blocks and two pairs of tool posts are furnished with each machine. The front and rear cross slide operate independently by screw feed, having a feed of 10 in. and can be arranged to feed into the work at any predetermined time, and at any desired relation, one to the other. The turret slide is of rugged construction and travels on ways so designed that all wear will be even and will not affect the accuracy of the machine. The turret slide has a 28-in. feed and no allowance needs to be made for revolving as the turret revolves at the extreme end of its travel. It has 13-in. longitudinal adjustment by means of a hand crank and is securely clamped in any desired position by three bolts, besides being located by the adjusting screw.



REAR VIEW OF THE MACHINE.

The turret has four stations upon which tools may be mounted, and with each machine an outfit of turret-turning tool holders, stems and cutters is furnished. Turrets with five or six faces may be furnished if desired. The turret is revolved by power through an intermittent pinion and gear and is so designed as to give an easy stop and start, the turret being stopped when the lock bolt engages, thus removing any shock from the lock bolt. It is clamped into position by a powerful binder working on the largest diameter of the turret seat. Levers are conveniently placed to release the binder and lock the bolt so that the turret can be revolved by hand. Both cross and turret slides are adjusted in relation to each other by conveniently-placed clutches.

All operation of the speed clutches, feed and quick return clutches is accomplished by a patented method operated by dogs located on the dog wheel or



FRONT VIEW OF THE MACHINE.

drum. This method gives instantaneous movement to the clutches and enables the feed, speed and quick return to begin at exactly the same place each time. An oil pump and piping and oil arrangement through the turret are furnished on machines handling material requiring a lubricant. A 24-inch three-jaw geared scroll chuck regularly accompanies the machine and is furnished with standard set of jaws and wrench. The chuck is provided with pilot bushings to receive pilot bars for supporting the tools during the cutting operation.

A swing of 35 inches is possible over the machine bed and 24 inches over the cross-slide. The travel of the cross-slide (front and rear separate) is 10 inches. A 15 h.p. motor is required to drive the machine, when motor driven.

NEW REINFORCED BEARING

The Lang Manufacturing Co., Ltd., Guelph, Canada, have placed on the market a bearing of most unusual design. This bearing is known as the Ridsdale reinforced bearing, and is of course covered by patents. It is a well known fact that the efficiency of your machinery depends to a great extent upon the bearings used, and the makers of this new bearing state that their patented bearing was first used in a case where a certain style bearing had given trouble for years.

Briefly, the idea is this: A spring or spiral made of a certain alloy is placed in the bearing cap or housing. Babbitt is next poured into the bearing in the usual manner, but in this case the babbitt is merely a holder of the reinforcements. These are shown at Figs. 1 and 2. At Fig. 2 is depicted the reinforcements in place, and held securely by the babbitt.

The big claim for this bearing is that there are no hard spots in such construction, also that even the cheapest grade of babbitt can be used with good results. The wear comes on the reinforcement and not on the babbitt itself. In fact in some cases the babbitt, if of a proper grade, can act as a lubricant. The makers also claim that it can be used in any bearing including those where the speed and pressure is extreme.

They state that this bearing has a tensile strength of 36,000 pounds per square inch against a much lower figure for babbitt only. They also claim that its resistance to crushing strain is much greater. Its resistance to heat is also a large factor. Instances have been cited where this type of bearing has run for some considerable time without a drop of oil.

Summarized, they claim as follows: This type bearing requires less attention and can use a cheap grade of babbitt as a binder. It requires practically no rebabbitting and will stand under endurance tests to prove that it will not heat up and seize.

PATENT DIAL GAUGE

The Albert Herbert Ltd., 1-3 Jarvis Street, Toronto, have supplied us with the details of a patent "Capstan" dial

VIEW OF THE GAUGE.

gauge which they have placed on the market. This gauge is shown in the accompanying illustration and the makers claim for it the following:

The gauge is said to fill the requirements for an accurate, speedy and economical method of testing the accuracy of production. It is used for alignment tests in machine construction, for testing finished parts, for testing concentricity of finished surfaces, and for setting up lathe, planer, milling, or other machine work.

The Capstan head screw, which is fitted to the spindle, is threaded 100 to the inch and is used in setting the hand of the gauge to zero on the test piece. The zero is thus kept always in one position —the top of the dial gauge. This is a great improvement as with most gauges it is necessary to turn the entire dial round for this purpose. This feature eliminates the possibility of the operator, by accident or out of curiosity, altering the adjustment, as the Capstan head screw must be deliberately turned by means of a tommy pin.

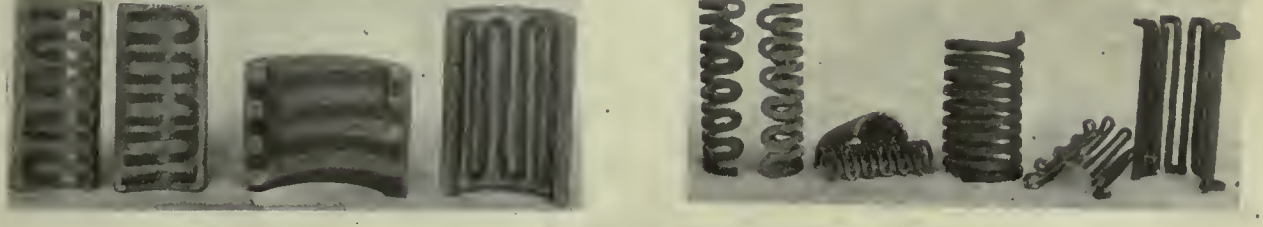
The push pin is conveniently placed and is used to lift the spindle or plunger above the part to be tested and allow it to gently descend on the work at one constant pressure—thus eliminating the personal touch. No downward pressure on the work can be given by the operator.

An adjusting screw is used for setting the tolerance to be allowed on the piece tested by simply rotating the knurled head of the screw. For example, after adjusting the screw to bring the hand to the zero mark on the sample or test piece on which a tolerance of say .002-inch high and low is allowed. The screw is rotated to bring the hand two divisions of the dial on the low side of zero. Thus set, any work passed under the gauge would read between the tolerance and two divisions on the left or high side of the zero mark. As the spindle thus has only a movement of .004 the speed in which work is tested is limited only by the operator. The push pin in such an instance is not used.

The dial, as can be noted, is mounted on a base. Various sizes and styles of bases can be provided if desired, and if required metric dials can be procured.

SIMPLE WAGON TIPPER

Many devices, some operated by hand and some by power, have been invented to "tip" a wagon so as to empty it of its contents. One of the most interesting of these devices, worked by hydraulic power, has recently been demonstrated by a leading British firm. The engine of the wagon drives two hydraulic rams, which raise the body and clear it of its load within half a minute. The whole operation is carried out by moving a single lever, this action being performed by the driver without moving from his seat.



THESE VIEWS SHOW NOT ONLY THE BEARINGS THEMSELVES, BUT THE REINFORCEMENTS.

Mechanical Accuracy

TAKE a hair from your head (the average is about 2½ thousandths of an inch in thickness) and if you could split that hair into ten strands of uniform dimensions, just one of those strands would give a fair conception of the closeness to a mean standard prescribed in more than 300 operations on our car.

"Our work calls for more than 5,000 operations in which the deviation from a mean standard is not permitted to exceed the one one-thousandth of an inch; more than 1,200 in which it is not permitted to exceed a half one one-thousandth, and more than 300 in which it is not permitted to exceed a quarter of a thousandth."

These statements appeared recently in a wide advertising campaign carried out in various national magazines, and were prepared to appeal to mechanical men in general.

Can you imagine such technical copy reaching the columns of popular magazines, even ten years ago?

It is only another proof that this is becoming more and more a mechanical age and that things are changing for the better.

Why are the limits held so close? Simply to obtain accuracy and an interchangeable product. We owe a great deal to the automotive industry in this respect, for they have been largely responsible for our seeking after interchangeability.

Working to fine limits became common practice in Canada during the days of the shell shop. We hear much of the shell-buster-funny chap no doubt. But we don't hear so much about many mechanics who had never measured anything much closer than a sixteenth.

Memory recalls one chap who used to carry a brass rule in his overalls pocket. He could work to sixteenths all right. The question of shells was put up to him and after a study of the required standards he explained that it was out of the question—it couldn't be done in his shop.

What happened? Simply that in a few months he was working in thousandths of inches and turning out a good shell.

Fine limits indicates high class machine shop and tool room practice, as well as excellence of design. Canadian shops should never drop from these standards of mechanical superiority.

Oil Versus Coal

REPORTS from Vancouver state that on account of the oil shortage, oil-burning equipment in boats and locomotives is being taken out and replaced by coal burners.

There is something in this move that may cause a number of very careful students to make one of those "I-told-you-so" remarks. For some time the view has been held that oil-burning equipment was being boomed out of all proportion—that it could never live up to all the advance notices that were being put up for it.

There is a shortage of oil, so marked in fact that it is not possible to secure the 70,000 barrels daily the Canadian Pacific requires.

There must be fuel for the automobiles, joy-riders and others, no matter if there is no fuel for locomotive and steamships.

Many a firm that has spent its good money in perfecting coal-burning apparatus could hardly be blamed for getting a little hot under the collar by the booming that has accompanied every move made by the oil burners.

The oil burning type has many advantages; it is easier to operate; it gives almost a maximum heat right at the start.

But when there is no fuel oil to be had, or when it is in very limited quantities, what then?

The oil burning equipment is desirable on railroads that run through wooded sections, for the foot-hill country of British Columbia, Oregon and other coast territory can bear gaunt testimony of the way in which the old belching locomotive used to strew its live coals on dry material along the right-of-way.

It is an expensive proposition changing over from oil to coal burning equipment. For a locomotive the cost might be from $10,000 to $12,000, while a fair-sized steamer of the ocean-going sort could hardly be altered for less than $50,000 or $60,000.

The coal burner will be with us for some days, and the part of wisdom is to use every possible means devised and improved for getting as much energy as possible out of every ton of coal burned.

The oil burner will be here, too. There is plenty of room for them both.

One Optimist in Business

THE remarks uttered by Lord Leverhulme at the recent opening of the extension of the Toronto plant come as a tonic at this particular time. So many men are preaching hard times, bad outlook, country going to the dogs, etc., that to hear a man who refuses to believe anything of the kind is refreshing. When this man is a practical, successful business man, who can back up his ideas with his money, and is doing so, his opinions are entitled to a hearing. Lord Leverhulme thinks that it would be a backward step to lower wages at the present time, and he is undoubtedly right in the main. To lower wages at the same time that the cost of living is about to be lowered brings the whole situation back to where it was when costs and wages were at their highest. It comes back to the old story, as the speaker emphasized strongly, that maximum production will support itself, by creating a demand, and giving a high wage to those engaged in industry. Of course maximum production depends entirely on the attitude of labor, and in this connection it is noted by some observers that in some shops where men have been laid off, the production of those remaining shows a very favorable increase. The orgy of extravagance, high living, and a false standard generally is passing away, and it is a good thing for us that it is. That there will inevitably be some distress before times are normal again is also, unfortunately, true. If employers generally are imbued with some of the spirit of Lord Leverhulme, and employees willing to live up to their part of the contract, there will be the minimum of distress, and the speediest readjustment.

A Piece of Good Advice

WHEN Mr. Lloyd Harris told the business men of Canada not to depend too much on the Government, he spoke words of wisdom. We do not mean by this the present Government, the past Government, or the future Government in particular, but Government in general as an institution. A government is after all only a collection of ordinary men, who have attained prominence and position sometimes through merit, and sometimes through the fact that having no particular ability, they can be useful to the stronger men in the Government that have. These several men, whatever their abilities, upon attaining place, have their whole outlook on affairs tainted with the view of the office holder, whose primary object is to retain office, and do what he can for the country next. It is obvious that it is vain to look to such an institution for leadership in any vital trade or business development. In fact, any country which depends on its Government to advance its business interests is usually disappointed. It is the enterprise and daring of the individual trader that extends trade, and although a Government can carry out the wishes of the business community to a greater or less extent, it is very rarely that they suggest anything. Generally speaking, Government intervention in matters of business is usually attended with loss and inconvenience to those in the business, as has been abundantly shown in Great Britain by the Government control of shipping. Probably the only exception of note was Germany before the war, but it must be remembered that there they had no representative Government in the sense that we have. Therefore, they had men in the various departments of the Government, who were specialists, and not politicians. The Government holds about the same position in relation to the country that a chief office clerk or office manager does to a big corporation, and should not try to overstep that mark.

Strength of Materials

OUR knowledge of materials, particularly metals, has increased to a great extent within the past few years, but according to Professor F. C. Jenkins, president of the Engineering Section of the British Association, we are, as yet, only on the threshold of that complete knowledge which is essential before we can really tell the cause of a failure, or provide with certainty against accidents.

He states as follows: surely an engineer should be able to say whether a cylinder is safe without dropping it from the roof or rolling it down the front doorstep to see if it breaks. The time has come when the fundamental data on which the engineering theories of the strength and suitability of materials are based require thorough overhauling and revision.

When one considers the matter carefully, the professor is not far from wrong. Judging from some of the formulae we have seen, it would be a much better plan to drop the part under discussion and see if it would break, rather than try to figure out the theoretical chances of its proving too weak.

This condition should not exist, and if sufficient research work is made in this particular field, there is no reason why the formulae can not be simplified to a great extent. We should not have to depend on actual physical tests, but should be able to figure with certainty the strength of our various materials.

Cases exist where theoretical tests alone would not suffice. For example, suppose some structure is being built on which life depends. In such a case both theoretical and physical tests are made. Every boiler must undergo a water test before being fit for use, the various members of a bridge must be tested for their physical properties, and so on.

These precautions are essential with all due respect to theory, because defects can, and do, occur in process of manufacture. Theory does not allow for such defects, therefore they must be checked up by physical tests.

A great need exists, however, of our present formulae being simplified. Here is a chance for the heads of our colleges. Let them concentrate on the task, for by so doing they will be rendering a real service to the machine tool industry.

Can We Harness Radium

IT is a well-known fact that matter is composed of infinitely small particles, called atoms, but have we any conception of the internal structure of an atom? Professor McLellan, F.R.S.O.B.E., in speaking on this subject quotes as follows: "The difficulty of investigating atomic structure might be realized from the fact that if the atoms contained in a litre box of bird-shot were enlarged to the size of the shot, they would cover the entire surface of the earth to a depth of eight inches."

The discovery of electrical elements had greatly facilitated atomic research—the positive element being the nucleus of the atom around which varying numbers of negative electrical elements called electrons perpetually revolve. The study of radium emotions, however, had been the most important source of the accepted atomic theory.

Radium had been formed at an early stage of cosmic evolution from the condensation of highly energized elements at a high temperature. Now that it had cooled to the temperature of the earth it was in a position to de-energize itself. This energy was dissipated in the form of streams of electrons and alpha rays, the latter being gistotopic helium and traveling at a rate of 20,000 miles per second. It would be the problem of the future to harness this enormous energy and put it to economic use in the form of heat, light and electricity.

Although no immediate relief to the power situation can be expected, it is good to know that a time may come when radium energy will come under our control and allow itself to be harnessed.

KEEP GOING!

"Motor World."

MARKET DEVELOPMENTS

The Steel Market Holds Interest This Week

Several Local Steel Men Left at the Week-End for Steel Centres of United States to Find Out Just How Matters Stand—Reports From Several Centres.

DEVELOPMENTS in the steel market are the outstanding feature of the week in machine, iron and steel circles. Some of those who watch the market closely believe there are symptons of a runaway market if those at the head of affairs do not hold the thing in check. The first answer of the corporation to the independents was the announcement—hardly made officially yet—that Canadian business would now be regarded as domestic trade by the United States rollers. For some time past Canadian orders have been regarded as export trade, and carried a higher price as a result. It means that there will have to be considerable readjustment in order to protect the business already on the books of the corporation, and some of it has been waiting there for a year now. Where a definite price has been given on a contract it is not considered necessary to make allowance, but where material is bought for warehousing, or where the sale of the product depends on current quotations, there will probably be a transfer of the business from the old figure to the new. At least that is the expectation in the Canadian market.

There are a number of inquiries in the market for machine tools and kindred equipment, but the trouble lies in the fact that much of it cannot be closed. In some cases it is hard for firms to finance the purchase now, as they are anxious to keep all available cash for working capital. On the other hand there is a marked tendency on the part of many buyers to rather glory in the fact that this is a buyer's market, and the firm that wants the business must come along and bid lustily for it.

The scrap metal market remains just where it was last week, in the dumps. Dealers will not guarantee to pay the prices they authorize, and there is almost nothing going on. Buyers are out of the market, and dealers are also in many lines. Prices are still downward, but no dealer seems to have the heart to batter down the present lowly list. The figures, though, are only nominal.

SUSPENSION IS ONLY TEMPORARY PROSPECTS BRIGHT FOR NEW YEAR

Special to CANADIAN MACHINERY.

MONTREAL, Que., Dec. 2.—The keener competition that features the trading in all lines of commodities foretells a further adjustment in selling prices. Mills are realizing that they must take a share of the losses incidental to a declining market, and the present policy seems to favor a disposal of surplus stocks before heavy production can be considered on the changing basis. There is, however, an effort of conservatism in taking the downward steps to avoid a fall that might have serious after effects, should the dormant demand, now supposed to exist, suddenly develop to an active reality.

Despite the fact that present demand is below normal, the feeling still exists that industrial and manufacturing requirements are only held in temporary suspension and that early in the year may see a return to a more healthy condition in respect to future bookings. Speaking of the relative cost of production, one dealer said: "It should be borne in mind that during the war exports of all steel and metals from the States were excessive, and that production was carried on in an extensive manner. For many months after the war this same condition obtained, but during the past year the rehabilitation of European countries resulted in re-establishing steel activities in Europe, and consequently the necessity of importing fell off, so that mills here and in the States had to look to their home requirements to absorb the output from the mills.

"This condition became more pronounced with the general falling off of trade so that curtailment in manufacturing was the logical outcome. Owing to many circumstances this lessening of activity meant a proportionate increase cost per ton in the making of the steel, as in many instances the overhead costs remained the same on the smaller tonnage output. The adjustment now going on is the first real move in this direction since the war ended, and as we must have it, the sooner the better." The steel demand in this district is rather quiet and will likely remain so during the month of December. Dealers, however, are not discouraged as reports and inquiries are of a character to indicate that placement of good business is only awaiting a more settled condition of trade.

The plate situation has developed no new features of interest other than a lighter demand. Shipyards are not so busy and material coming in for this purpose shows a marked falling off. The sheet situation is easier and the supplies are more readily obtained; this applies more particularly to black sheets as the call for galvanized is still good. Queen head and fleur-de-lis are down 50 cents per hundred, the respective quotations being $13 and $12.50 per hundred.

Further Declines in Metals

The further reductions that have been made in the price of ingot metals indicates the effort that is being carried out in the universal adjustment to a more reasonable working basis. This is not literally true, as production costs today are in excess of what they should be in comparison to what metals are selling for on the current market. What is actually taking place is the liquidation of accumulated stocks, and this will probably require some time, especially as consumption just now is below normal.

The demands from Europe since the war have rapidly declined and no corresponding outlet has been found for American metals, the consequence being that refiners here have had to adjust their output to existing needs, which, at present, is in excess of trade requirements, and in face of the high production costs the stocking of metals has no inducements for the refiners. Ingot metals are marked down from ½ cent to 1 cent per pound. In copper products, bars are quoted at $35; plain sheets at $40; copper sheets, tinned, at $43, and planished copper sheets at $47. Lead sheets are also easier, the price ranging from $10 to $10.50 per hundred pounds. Brass rods, sheets and tubing are likewise lower, the quotations being 30, 38 and 42 cents respectively. Copper tubing, seamless, is now 44 cents per pound.

No Market in Scrap

"The prices you are quoting," said a dealer in old materials, "are just as good as any other, as trading at present is not influenced by the price. We offered 13 cents just this week for a quantity of copper wire, but the sale was not made, and we are just as well pleased. It would have meant carrying it in stock, and this we are not anxious to do." The listless character of the old material market is not conducive to enthusiasm on the part of dealers, and the apparent disinterest reflects the trade depression. Some little movement is always in evidence but the volume is very light.

Dealers look for a quiet period for the remainder of the year, and do not anticipate excessive activity for some months, although many are hopeful of a gradual betterment after the holiday season. Prices quoted might be shaded a little, but lacking an actual sale, the list may be considered as that generally prevailing throughout this district.

NEW STEEL PRICES SOON EFFECTVE

Trade in Canada Should Get Advantage of These in a Short Time

TORONTO.—The new prices that are coming to the steel market formed the chief topic of conversation this week. In fact so interesting was this matter that the week-end saw several of the local steel merchants hurrying off to New York and other steel centres to see just where they stood, and what the chances were for stability, many of them seeming to think that there were present all the makings of a runaway steel market which might develop before many days were over.

The machine tool market is quiet. At this season of the year there is generally a period when little business is in the market, but the facts are that right now it is more than seasonably dull, although there are a number of very good inquiries in the market. The feeling is growing that a frank statement on the part of the machine tool builders in regard to selling prices and policies would do something to clear the air, and allow the work of placing business to proceed. Right now the price change is a sort of checkerboard affair, as some of the makers have announced reductions, while others have not, and their agents in this part of the country seem to be quite satisfied that they will not name any lower selling costs.

There is generally a desire on the part of firms to make as much of a clearing-out at this time of year as possible, in order to keep up the total figures for the year, especially if their fiscal year ends with the calendar year, and this is the practice with the majority of the firms. No doubt there is some of this being done, but not to the extent that might be imagined. For instance, one report tells of the sale of a new radial drill, never taken out of the crate, that went out at almost half the regular price. Other sales of this sort are also heard of, but after all they are only incidents in the market, and do not indicate at all that the general policy of selling is moving in this direction.

Price or Uncertainty?

"We have a number of very attractive inquiries, but we can't sew up the business," was the remark of two different offices this morning.

"Why? In some cases they find it a little hard to finance the business, wanting to hold on to all the available cash they can. We are looking for something a little easier in this line before very long.

"Then again there are buyers who seem bound to ride around on the strength of the fact that this is more of a buyer's market than it has been for some time past. It is not an unusual proposition now for a man to have the specifications for a machine up his sleeve, and go around as though saying, 'Here's what I want, and the man who can come across with the most attractive looking proposition is going to get the business."

Then, again, there are reports of where firms and salesmen cannot come to an agreement regarding the price. There is one case where a nice order is waiting for a certain line of equipment, but there is a strong difference of opinion over the figure, and so far it has not been settled.

The Steel Market

A stock list coming to one of the local steel warehouses this morning conveyed the information that one of the independents offered sheets at 5.25 for immediate shipment. Formerly, when prices looked as though they would have to come down, the independents reduced business on their books from 8c to 6.25, largely with the idea of protecting it, but that is as far as they had come previously, while the new price

POINTS IN WEEK'S MARKETING NOTES

Cleveland does not deny that there is a slump, but feels sure it will be on the mend by the New Year, and normal by April.

—

Tendency in the machine tool business will be to cater to a diversified custom in future instead of specializing on one line.

—

Steel Corporation prices now are the ruling factor in the markets, most of the independent mills having adopted them.

—

The price of sheets has declined, but the lower rates have not had the effect of stimulating buyers.

—

Bessemer and basic are still declining but the decline is not so rapid as has been the case lately.

—

The local machine tool market has quite a few good enquiries out, but business is rather uncertain.

—

One independent mill is offering the Canadian trade black sheets at 5.25 base, this being the lowest figure given here yet. It cuts under the rate that has heretofore been given by the Steel Corporation.

—

U.S. reports indicate that if the new steel market revives buying of steel, there will be better business in sight for machine tool trade.

—

Pittsburgh claims that the new prices on steel are not bringing in any new business. Buyers look for more cuts and are waiting.

—

The local scrap market will answer to almost any reference that is made to it, provided it is uncomplimentary and indicative of stagnation and inaction.

—

Dealers having lines that are sold to farmers report a very active trade. For instance, engines are selling rapidly.

—

Firms that are having the hardest time now are those that specialized almost entirely in making parts for automobiles. They narrowed their field in that way to such an extent that when the auto business fell off they were almost done for.

—

Prices published this week may be changed on short notice, so allowance should be made for that.

they are quoting means that they are under the Steel Corporation price as it has been quoted here. The Corporation price to Canadian users has been all along 5.35.

The United States Steel Corporation is now prepared to regard Canadian business as domestic rather than as export business. This statement held good from the first of the week on bars and structural material and a similar statement is likely to come out at any moment governing the selling of sheets and other lines. This is a concession that has been looked for for some time back, and one which the trade in this country formerly enjoyed.

"How will existing business be attended to in view of the cut that has been made?" Canadian Machinery put that question to the Canadian manager of the U. S. Steel Products. It is something that the trade looks for at once when a new price is announced. This is the plan, as we understand it:

When a customer has figured on a definite contract, and has placed his order for the steel at a figure that will allow him his legitimate profit, he is not entitled to a reduction to meet the new market, for there is no necessity of him doing so in case the contract is still standing. On the other hand, if a firm or a warehousing concern has placed an order that they will have to resell, they will be protected on the new price. There may be a few variations from that programme, but as we understand it, that plan is substantially correct.

Some of those who are in the market all the time profess to believe that there is the makings of a real runaway market in existence if a certain amount of care is not exercised. Some dealers believe that the Corporation will now find it necessary to protect their own bookings.

The Scrap Market

Nothing is changed in the scrap metal situation, and it remains in about as dead a condition as could be imagined. Dealers will not state whether or not they will pay even the rather lowly price list which we publish in another column. Although the figures were furnished by the dealers themselves, they will not guarantee for the present to pay them unless they have some place where they can place the material.

The Matter of Wages

Labor is shifting in many cases. Machinists are working in several plants for 65 and 75 cents per hour where $1 was the rule before. For the present at least that fine old idea of "not liking your job" has ceased to be. It's a case of "have you got one?" The best men are being retained, and figures show that these men are working harder so there is a consequent improvement in production.

Another market being watched closely is steel, and it is mostly a waiting game to see when it is going to hit bottom.

This is Interesting

Speaking of association gatherings, one of the large builders of tools tells me that they all go to the annual convention—just finished a week or so ago in New York. Well, when they are there it's a case of scratching each others' backs and making statements about there being no cut in their prices. Then on the way back from New York many of them get out their lists and put the axe into them.

But after all—and this is from a visit to a number of centres, Cleveland, Pittsburgh, Erie, Canton, etc., there is a feeling of splendid optimism. Business has been running mad in some directions, and there is a determination to get down to a more secure foundation, and once that is done it will be a case of full speed ahead.

NARROWED THE FIELD BY NOT CATERING TO DIVERSIFIED TRADE

Special to CANADIAN MACHINERY.

CLEVELAND, December 2.—The firms or cities that have been taken up largely with supplying machinery, material or parts to the automobile trade have learned that it is not wise to put all the eggs in one basket. The dependence on one line has meant the neglect of developing others that might have been good to them now. They find that through trying to reach a very high efficiency in this line they have narrowed their field.

The best thinkers around this district, men who are heavily interested in the machine tool, iron, steel and metal industries, make no bones about the matter. They say they are caught in a slump and that it is a real slump, but in the next breath they tell you that it came quick and hard, and is going to move away rapidly. If one were to make a summary of all these opinions, a conservative answer would be that the start back will be around the first of the year, and that by April the new movement will be well under way.

These firms that were so geared up that they sank or swam with the automobile trade are quietly saying "never again," and are now preparing to cater to a much more diversified field. Erie, they tell us, is the third city in the world in the diversity of her manufactures, and the tone of business there right now is absolutely the best to be found in this whole district.

Pittsburgh can best be described as waiting.

One War-Time Lesson

Firms that are in good shape are going carefully in order to keep their credit sweet. They are curtailing expenses and making more investigations before placing advertising contracts. And right here is a peculiar development. A short time back advertising was looked upon by some of the firms as a good place to dump some of their surplus in order to keep it from the Government. New equipment was often put in on the same basis. But this advertising done by many firms on this rather loose basis has been the means of convincing the firms that advertising is a real, positive force, and these newer firms are looking upon it as a real factor in their business development. They now look upon advertising as an investment and not as a place to hide profits. There is a stated appropriation now in firms that just used to "spend money."

Travellers are working their territory harder. They have instructions not to make long jumps. Sales managers in some cases have taken over the work of the advertising department.

Some sales managers are working half crews all the time, and others, in order to hold their organization, work crews half time. This latter seems the more favored idea, but it cannot always be done because they must work them long enough to give the men enough in their week's wages to live on.

CHANGE FROM OIL TO COAL BURNER

Scarcity of Fuel Oil Makes it Necessary For C. P. R. to Alter Equipment

Vancouver. — The Canadian Pacific Railroad Company, on account of the acute oil shortage, is changing all its equipment, including steamships, to coal-burners.

It is estimated that the change will cost close to $60,000 for each steamer and $12,000 for each locomotive. The first coal-burning engine used by the road in the last five years left the station here last night with a transcontinental train.

H. W. Brodie, general agent of the company in the West, said that the oil shortage was due to the fact that the Standard and Union Oil Companies could no longer afford to supply the road with 70,000 barrels daily. He had heard, he also said, that the United States Navy Department was about to take over the Union Oil Company for its own use, and that the Standard was too busy supplying fuel for automobiles and transportation in the United States to provide for Canada.

ALL ON CORPORATION PRICES— BUT WILL THAT SCHEDULE LAST?

Special to CANADIAN MACHINERY.

PITTSBURGH, December 2. — Late last week the remaining independent steel makers came down to the Steel Corporation prices on bars, shapes and plates. More than a month ago an independent at St. Louis quoted the corporation price on plates. Later a Chicago independent came down on bars and over a week ago some Cleveland mills were quoting the corporation prices. However, on Wednesday of last week a canvass showed that five or six large independents were quoting 3.00c on all three products, the corporation prices being 2.35c for bars, 2.45c for shapes and 2.65c for plates. Thursday was a holiday and Friday morning an independent in Youngstown and an independent in Pittsburgh began quoting the Steel Corporation prices, the others immediately following, as it requires only a few hours for information of this sort to get around the trade. The established custom in the trade is that when a buyer is quoted a cut price by a certain mill he does not place an order at the cut price, but immediately tells all the other mills about it.

The reductions represented a case of the mills practically running out of orders at higher prices. The larger mills were not expected to run out nearly so soon. A couple of months ago several were claiming to be filled with business at least to January 1, if not longer, but it seems enough tonnage was cancelled to make a difference of several weeks. There is some tonnage left on books, but not a great deal. In general, the remaining tonnage will be adjusted in price to meet the new market.

Return to Industrial Board

The Industrial Board prices, representing the second reduction in steel prices from the war control schedule, became effective March 21, 1919. The Steel Corporation has consistently adhered to those prices. The first thing the independents did was to cut the prices, practically all the independents selling at cut prices during April and May, 1919. Afterwards, as they filled up, they began to look to the Steel Corporation to advance prices. This the corporation would not do. Late last year, or about a year ago, the independents began advancing prices on their own account, and at the beginning of this year practically all the independents were at advanced prices, a notable exception being the tin plate mills. When the time came to make contracts for the second half of this year the independents demanded higher prices on most of the business, but not on all. Within the past two or three weeks the independents returned to the Steel Corporation price on tin plate. Now the action is followed by the independents on bars, shapes and plates. The remaining important products are sheets, pipe and wire. On these the independents are still above the corporation. The reason the independents are still above the corporation on these products is that they still have a considerable tonnage of business on books, but of late this has been greatly diminished by cancellations, and it may not be long until these products fall in line.

Sheets Decline

Sheets were so extremely high in the independent market that they could decline a long time before getting to the Steel Corporation or Industrial Board level. For a couple of months or more the black sheet market declined at the rate of about a quarter cent a pound per week, but in the past fortnight there has been a decline of one cent. One can readily buy now from several independents at 5.00c for 28 gauge and on an attractive order even this price would probably be shaded $2 or $3 a ton. Galvanized sheets can be had at 6.50c. At the beginning of last week one mill was quoting 6.70c. others being at 7.00c or higher, but at the close of the week there were several sellers at 6.50c. In blue annealed the common quotation is 4.50c, but this basis could probably be shaded a trifle on the lighter gauges, while it could be shaded considerably on the heavier gauges, those that can be produced by light plate mills.

No Buying

Reduced prices have not brought the independents any additional business, nor was it expected that business would be created by this means. Buyers are bent upon having the smallest possible inventories and commitments January 1. The business of jobbers and manufacturing consumers has slowed down very greatly and naturally the buyers will not purchase from the mills except as they have occasion to sell or consume the material.

Manufactured Products

The market for cold finished steel bars of late has been 4.00c, with some producers still quoting 4.25c. The market was 3.60c when the makers of cold finished steel bars were getting their bars at 2.35c, but prices were advanced afterwards even by makers who were getting their bars from the Steel Corporation. The question now is whether the makers will reduce their prices at once below 4.00c. Thus far they show no inclination to do so. Standard railroad spikes remain at 4.00c, but this price is too high by comparison with bars at 2.35c. Before the war, when costs and profits were less, the spike makers used to consider a spread of $9 a net ton between bars and spikes as a fair one.

Mill Operations

Independents as a whole are probably operating at an average rate of less than 50 per cent., while the Steel Corporation continues to operate as well as at any time in recent months, being very well supplied with business. A few independent mills are closed entirely, but such closings are not permanent, being for the purpose of accumulating specifications. For some time to come, and until demand develops, independents are likely to close for two or three weeks at a time and then run for a week or two at a fair rate, this being much more economical than to maintain a low rate of output continuously. The Steel Corporation is likely to run for months at nearly if not quite its usual rate.

Pig Iron

Bessemer and basic are down $2.50 in the week and foundry $2, the market being now quotable at $37 for foundry, $37.50 for Bessemer and $35 for basic, f. o. b. valley furnaces, freight to Pittsburgh being $1.96. The declines in Bessemer and basic occurred by way of there being offerings rather than quotations against actual inquiries. In foundry there were one or two small sales to bring out the lower quotation. The bottom, of course, is not yet reached, but as declines of $13 in foundry, $11 in Bessemer and $13.50 in basic have occurred from the top points reached last August it is expected that further declines will be at a slower rate. Furnaces admit that prices will decline to cost, but there is a question where the cost line lies. No close figuring can be done as long as the coke market has not settled. For the past fortnight the Connellsville coke operators have maintained spot furnace coke at $8 to $8.50 and furnaces consider such prices ridiculous, being in doubt whether they would pay even $6.

Semi-finished Steel

The first sale of any semi-finished steel at the Steel Corporation price occurred a few days ago, a sheet mill in the Pittsburgh district buying 2,000 tons a month of sheet bars for December, January and February at $47 Pittsburgh, or $48.40 delivered. The identity of the seller is not disclosed and the independents do not yet admit a willingness to sell at the Steel Corporation prices.

According to tests carried out by the United States Forests Products Laboratory on fences of charred and untreated posts of various species, charring is of little value in protecting the butts of fence posts and telephone poles from decay. The charred posts proved in these tests to be even less durable than the untreated ones.

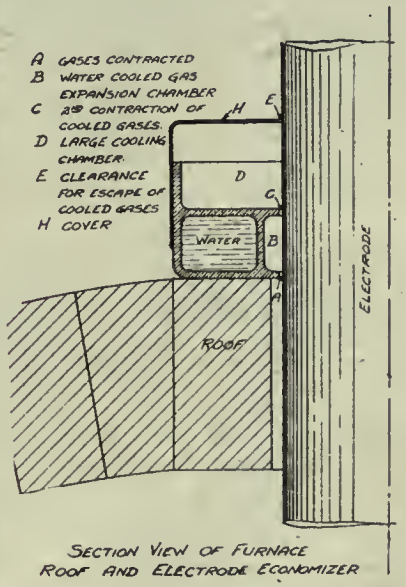
HEAT LOSSES IN OPERATION OF ELECTRIC FURNACES

(Continued from page 498)

ling of electrodes and other troubles caused thereby. These economizers have been fitted to a number of furnaces and have stood up remarkably well. Some have been in constant operation for six months and are as good now as the day installed. The invention is covered by patents, but can be supplied for all types of furnace. A full description of the device was presented at the recent meeting of the Association of Iron and Steel Electrical Engineers, by Mr. E. T. Moore, chairman of the electric furnace committee, but a brief description will probably interest.

The Brooke economizer depends for its action on the well known scientific fact that hot gases under pressure, if suddenly allowed to expand, quickly lose their high temperature. The gases generated in an electric furnace are only combustible at high temperatures and in the presence of oxygen. All other cooling rings simply content themselves with cooling these burning gases. In the Brooke economizer the gases never do ignite, the roof ports and the electrode are kept reasonably cool and the gases leaving the furnace are at too low a temperature to ignite.

The gases pass first of all in between the electrode and the port hole roof and



SECTION VIEW OF FURNACE ROOF AND ELECTRODE ECONOMIZER

FIG. 2—DETAIL OF COSTRUCTION.

then through the small clearance marked A, Fig. 2, into the cooling ring and into a relatively larger chamber B, whcih causes the expansion of the gases and thereby giving up a large amount of sensible heat in the gases. This heat is absorbed by the water in the cooling ring. From chamber B they are once more contracted through the small clearance C and then passed to a very large chamber D for a second and chief expansion. The design differs slightly with amorphous or graphite electrodes, but the effect is that no flame is seen from the top of the furnace and the electrodes do not pencil off.

The attached photograph, Fig. 1, shows a 3-ton Greaves-Etchells furnace at the Dodge Steel Co., Tacony, Pa., and illustrates the actual size of the cooling ring. It will be noticed that although the electrodes are withdrawn and the furnace is pouring there is no flame or reduction of diameter. Even when carbon is thrown on the slag no flame appears. On a recently installed four-electrode furnace the monthly figures were 12 pounds of graphite electrodes per ton. The average over six months was 12½ pounds, with a power consumption of 550 kw. hours per ton of steel.

Tests are now being made on a furnace fitted with the special type cooling ring, but it can be seen with the naked eye that the temperature of electrodes is far less, and therefore considerable saving of heat and power does take place.

The Labor Temple, Vancouver, B.C., is to be remodelled for a technical school.

Excavation has commenced on the site of the new Gendron factory, north of Danforth Avenue, Toronto. It is expected that the factory will be completed about the end of February and will employ about 500 men at the start.

A SIGN OF INCREASED PRODUCTION

Every Shipment of Geometric Threading Machines Means Increased Production and Decreased Costs in the Shops Where They Are Consigned.

Small threaded parts are correctly duplicated in shortest possible time. These machines thread work which cannot be handled on the ordinary Screw Machine or produced economically in any other manner.

There are three sizes—½-inch, ¾-inch and 1½-inch. The threaded diameters range from ⅛-inch to 1½-inch inclusive.

Make Screw Thread Cutting the most satisfactory operation in your plant.

NEW YORK LOOKS FOR MOVE TO BETTER BUYING NEXT YEAR

Special to CANADIAN MACHINERY.

NEW YORK, Dec. 2.—The development of the past week of outstanding importance is the announcement by leading independent manufacturers of steel products that they have reduced their prices on plates, shapes and bars and some other products to those which have been in effect since March 21, 1919, on all orders taken by the United States Steel Corporation. While the major products have come down, certain other products such as rails, wire and nails, sheets, etc., are still higher, as quoted by independent mills, than the prices quoted by Steel Corporation subsidiaries.

The reduction in steel prices has a direct relation to machine-tool trade, as any revival of business in iron and steel lines must of necessity be preceded by an adjustment of prices on steel that will bring buyers back into the market with a greater degree of confidence that the bottom had been about reached.

The machine-tool trade sees ample evidences of a willingness on the part of manufacturers to buy shop equipment, but the general uncertainty has caused them to hold aloof. Even actual and pressing needs for machine tools have been put off until after January 1 in numerous instances. The readjustment of steel prices by independent mills is an important step toward the expected revival of business next year. If the railroads, for example, buy steel in fairly large quantities they will surely buy machine tools, as many of their shops are greatly in need of complete rehabilitation. Several large railroad lists have been held up by Eastern roads until after January 1, but there is a strong expectation that they will be issued early in the new year.

Current business in machine tools is very light. Some machine-tool builders are not booking enough business to pay expenses. Dealers have not done more than 10 to 15 per cent. of a normal business during November. There is no expectation of any buying in December, but the turn of the year is being looked for with interest and a greater feeling of optimism than has prevailed in many weeks.

GOODS WILL MOVE IF PRICE IS RIGHT WAR PRICES AND WAR PROFITS ARE PAST

THE final chapters in the industrial liquidation are now being written. The retailers are at last falling into line, and where they have shown a disposition to meet their customers' views as to prices, they have demonstrated that there is an enormous latent purchasing power. There is no doubt of the ability to move goods into the hands of final consumers, provided the price is right. It should not take long to clean up present stocks once the retailers, generally, adopt the policy that the leaders have already started. Then will follow the replacement of stocks which, thanks to heavy reductions in price by manufacturers, can be done to good advantage. Of course, all this means that war prices and war profits have gone for good. All must disabuse themselves of the idea that these can be retained at any stage. But the point is, first, that there is now promise that the period of industrial recession will be comparatively short-lived and secondly, that even what used to be considered normal profits would, in the large majority of cases, amply support present stock prices. In this way Hayden, Stone & Co. review the market situation in their weekly letter.

Even the most stubborn of the obstacles to a return to healthy active conditions is beginning to give way, they continue. We allude to the question of wages. During the war period, these were largely paid out of capital. Of course, this could not long continue without complete disaster. Henceforth, they will be paid according to the ability of industries to meet them. It will be, in the end, more satisfactory to be assured of a certain wage, even if less in dollars and cents, that will have a purchasing power equal to a normally higher but actually far more uncertain remuneration.

There is, however, one rather disturbing thought; our prosperity in the last five years has been largely based on Europe's demand for our goods, at abnormal prices. This demand will, henceforth, not only be radically diminished, but will be replaced by the ability of Europe to compete in our own markets. Even after severe markdowns, our prices will be very attractive to European producers, especially on present exchange rates. Europe still owes us enormous debts. These cannot be paid in money; they must be met with goods. Whether it is better to let these goods in at such prices as to jeopardize our own manufacturers, or to protect them against this influx, even if to do so it may be necessary to forego payment of this debt, is a deep economic problem, which it is hardly the function of this letter to take up, but the mere fact that such a problem exists emphasizes that world competition is being rapidly restored and that some outlet must be found for our own goods, as our productive capacity is probably well in excess of our own needs. We mention this to bring out the fact that while it is to be hoped that industry will, in the course of a few months, be again fairly active, the element of competition will be very prominent and the margin of profit correspondingly small.

HAVE NO MORE ORDERS ON HAND

Director of Vickers Ltd., Says Not Much Future for Shipbuilding

Montreal.—The "Canadian Leader," 3,340 net tonnage, the twelfth ship built for the Canadian Government Merchant Marine, and the sixth this season, by the Canadian Vickers Ltd., was successfully launched from the yards of the company.

At the subsequent reception A. R. Gilham, managing director of Vickers Ltd., stated that his firm had launched more than 50,000 tons of shipping during the current year.

He painted a gloomy picture of the conditions that now confronted his company and the Canadian shipbuilding industry in general. More than 40 per cent. of Canadian shipyards had sung their swan song, he said, and, unless Government aid were forthcoming the same fate confronted the Vickers company. "The sorry fact is," said Mr. Gillham, "that we have no orders for next year. We have two boats now on the stocks which we hope to launch next April, and if there are no further orders by that time the yards will be forced to close."

KEEP AS MANY ON AS POSSIBLE

C.M.A. at Conference Discuss Ways of Dealing With the Present Situation

At a joint meeting of the Ontario Division executive and Toronto branch executive of the C.M.A., very full consideration was given to the problem of unemployment throughout the Province of Ontario. The executive viewed with apprehension the present condition of unemployment generally, but they had in mind that there is always a certain amount of unemployment at this season of the year, which is accentuated by the fact that a number of unemployed, who do not belong to this city, locate in Toronto in search of work, thus aggravating the local labor situation.

The executive strongly recommended to all manufacturers to do everything possible to prevent the laying off of too many men where it is at all avoidable, and it was agreed when a reduction of working time is necessary to carry out the reduction by closing for whole days rather than for parts of days, so as to minimize factory disorganization and inconvenience to the workers and thereby keep as many men employed as possible.

Aikenhead's

AIKENHEAD'S large stocks enable them to supply "Everything in Tools." They are prepared at all times to fill your requirements promptly—be they large or small. This, and efficient, courteous service has made Aikenhead's, **Canada's Leading Tool Supply House.** Give them a trial.

Johansson

The World's Standard of Precision Gauging

EVERY machine shop, inspection department, and manufacturing plant must agree and know, beyond possibility of dispute, just precisely what constitutes an inch or any fractional part of an inch. They must all use measuring tools which insure quick measuring with the least possibility of error.

Johansson Gauges are the accepted standard of measurement the world over. They are the most simple known method of measuring and are guaranteed accurate to 0.00001" at 68° F. They are self checking so that any inaccuracies due to accident or abuse are readily discovered. They not only answer the gauging needs for the present, but for the future regardless of how the work may change.

The new reduced prices of Johansson Gauges make them applicable as actual working tools in every machine shop.

Get fuller particulars from Aikenhead's. Write to-day.

Wahlstrom Automatic Tapping Attachment

THE Wahlstrom prevents the tap from jamming in the hole by keeping the lands free from chips—consequently there is no tap breakage. The chips are freed by an oscillating motion which duplicates the simple to-and-fro motion of hand tapping. For tapping in soft materials the oscillating motion can be changed to a continuous revolution.

Made in two sizes. No. 1 takes taps of all sizes from 5.40 to ½ inch standard. No. 2 takes taps from ¼ inch to ¾ inch.

Aikenhead Hardware, Limited

WAR TIME PRACTICE WILL NOT HELP IN THE PRESENT MARKETS

RIGHT now is the time when a man must show whether or not he has any qualities as a manager, salesman or financial adviser.

That is the opinion of one well-known Toronto manager, speaking to Canadian Machinery this week. Here is the way he figures it out:

"During the war we got a poor idea of what business amounted to. There was nothing in the way of real serious selling done. Now there may be some variation from that statement, but as a rule it will hold true. The shell business was not sold. It was taken away, and there was only one necessary thing to do, viz., produce good shells. Any lessons of the war were for those in the production department, and I think we are a better people industrially than we were before on account of the experience we gained in that way.

"Many firms that came into being since the war have a real situation to face now. In many cases they have not been in business long enough to have seen such seasons coming and developing as we are facing now. There is nothing unprecedented in the developments that we are face to face with today. Many of us have gone through the same thing before, and have managed to come out in fair shape recently, although sometimes more or less ruffled up.

"You may know there is a tremendous difference between producing, with the government taking the product away, and financing much of the work, and getting out on your own hook to produce, finance and sell a certain given line. That is where we have got to do real hard work now, and as I remarked before, right now gives a man a good chance to show what kind of managerial stuff he has in his system. Problems of financing and selling are, to my notion, the real tests of good business training and capacity. Give me the man who can adjust finances and keep the sales on the move and you can take over the rest of the organization."

GALT FIRM GETS THIS BUSINESS

The Exchange Rate This Time Worked in Favor of the Canadian Firm

Irritation over United States exchange hold-up has been the means of securing for Messrs. Goldie and McCullough Ltd., of Toronto and Galt, a large order for boilers and heavy machinery for the new municipal lighting plant at Murwillumbah, Australia. Several American machinery manufacturers tendered for the business. The order is an important one. Mr. A. McArthur, of the Empire Engineering Supply Company, Sydney, Australia, at present at the Walker House, had the satisfaction of booking this order, and is expected to throw other important trade to Canadian manufacturers.

Mr. McArthur is now in consultation with officials of the Canadian Manufacturers' Association, urging that organization to inspire greater activity among its members to take advantage of present opportunities and lay the foundation for a large volume of the Australian trade. The Antipodean Commonwealth now has a tariff of 40 per cent. against all importations foreign, with a preference in favor of Great Britain and such of her Dominions as are on the same plan as Australia with respect to white labor conditions. Mr. McArthur says that if Canadian manufacturers are prepared to quote reasonable prices in many lines of articles, Australia is in the market with a large volume of orders to be filled.

PROTECTION FOR THE STEEL MILLS

Case Presented by the Steel Co. of Canada at Hamilton Sessions

Some of the bigger interests from the financial standpoint which sent representatives to claim a continuance of tariff protection at the Hamilton session of the Tariff Commission were the Steel Corporation of Canada, the iron and steel industry of Hamilton, Dominion Foundries and Steel Limited, the flat glass industries, the Spirella Company of Canada, all the above being located in Hamilton, and the Canadian Yale and Towne Co., Ltd., of St. Catharines. The statement of the Steel Corporation of Canada as presented by Mr. Robert Robson, president, was an exhaustive one, and it followed out the attitude adopted by the large corporations in the same business in Nova Scotia and at Sault Ste. Marie. As Mr. Hobson put it, the tremendous advantages of the self-contained industries across the line make it particularly difficult for the Canadian plants to compete with them, and he had plenty of statistics to show that the steel industry in Canada is subject to keenest competition from United States producing units owing to greater capacity, shorter freight haulage, and convenience to markets. The general statements from the different iron and steel interests were consistent ones of growth, with increasing payrolls and larger output, but their contentions were also consistent in the claim that if they are to continue to fill the dinner pails of the workers they must have protection for their produce.

STEEL PRICES AT MARCH '19 LEVEL

Largest of the Independents Announce New Prices at Which They Will Sell

Pittsburgh.—Return of steel prices to the base established by the United States Industrial Board, March 21, 1919, developed here on Saturday, when the Jones and Laughlin Steel Company, the largest of the independent interests, adopted new selling rates on certain finished steel products.

This reduction, the first to be made by independents in the Pittsburgh district, will not affect the wages, it was understood, of the approximately 25,000 persons in the company's employ.

The new prices, which are effective immediately, are: Bars, $2.35; structural sheets, $2.45; plates, $2.65, base Pittsburgh. Adjustments will be made on the prices for wire and cold-rolled steel products.

Independent steel companies of the Youngstown district, employing about 30,000 workers, announced to-day they will meet the reduction of prices announced to-day by the Jones and Laughlin Company of Pittsburgh, the cut to be effective at once.

Heads of the three largest independent corporations here declared a readjustment in the cost of both coal and labor will have to follow. They said that wherever labor costs with the independents are higher than the United States Steel Corporation, the wages will have to be reduced.

MANY THINGS TO BE CONSIDERED

Mr. Hollinrake Says C.M.A. Urges Members to Keep On As Many as Possible

Discussing matters of unemployment, T. A. Hollinrake, a president of the Toronto branch of the Canadian Manufacturers' Association, reminds the public that anxiety is not confined entirely to those who are out of work.

"The attitude of the C.M.A.," says he, "has been favorable to Labor. We have a committee on industrial relations which is keeping in close touch with the unemployment situation.

"At the present time it is the C.M.A.'s policy to ask all members of the association to keep as many employed as possible, even if they might easily be able to dispense with them, feeling that at this time it is a necessary and wise action.

"The power situation has been heart breaking to employers. That condition might very well have agravated un-

employment. But employers as a whole bore the brunt of the power shortage and kept on their men, even though idle.

"Unemployment depends on the state of business. And manufacturers are experiencing no little uneasiness because of the tariff question, luxury and business profits taxes. Manufacturers are hampered in many ways just now, and the result is not beneficial as regards unemployment."

PIG IRON TRADE

The iron market is at present the quietest in years, and prices are being determined by small transactions on the Philadelphia market. Some small sales were made during the past week by Eastern Pennsylvania makers, up to $44 for No. 2 plain (1.75 to 2.25 silicon), although the usual prices are from $41 to $43 furnace. Malleable is offered at $46, while basic, in absence of business, is nominal, but could be secured from eastern makers on a basis of $35 valley or $41.16 del.

Pig iron dealers in Chicago who have been familiar with the market for years say that the present situation is the quietest ever experienced. There is not only practically no inquiry, but it seems impossible to interest any one in taking either spot iron or future tonnages. The policy that is seemingly followed with furnaces is to go out of blast rather than continue production under present conditions. Three furnaces have blown out in the South Chicago district. Northern iron is nominally quoted at $46 and southern $42.

Basic iron is being offered by a valley merchant furnace in the Pittsburgh district at $35 and Bessemer and malleable at $37.50 a ton as compared with prices of a week ago. No. 2 foundry (1.25 to 1.75 silicon) is quoted at the same price as last week—$39.

Pig iron sales in the Cleveland district are mostly of a resale character. Furnace prices are difficult to determine because the producers are either not selling at all, or in very small quantities. Carload sales were made by producers during the week at $42, base Cleveland furnace, and $41, northern Ohio furnace.

The volume of resale iron on the St. Louis market is increasing. It has been stated by men long in trade that they have never seen such a rapid change from a period of seeming scarcity to one of large surplus. Agencies quote $42 for No. 2 (1.75 to a 2.25 silicon). This price however does not mean anything as it is not being realized on sales.

Production is being curtailed sharply as producers claim that costs have not declined materially, even despite the heavy cuts in coke prices and they are unwilling to pile iron at present levels.

Despite the fact that foundries have further curtailed production and trading is almost at a standstill, there is a more cheerful undertone in the Boston market. Dealers who had given up hope of selling first half iron before the first of the year now seem to think that some buying will take place before the middle of December. A Connecticut consumer bought 300 tons of resale Virginia iron at $47.26 del. for No. 2X 2.25 to 2.75 silicon, which is approximately $40 furnace base.

On the Buffalo market there is very little furnace iron moving and transactions in resale have diminished considerably. The selling price in resale is varied. One lot of 500 tons sold at $43, while another small lot sold at $40. One furnace has quoted $44 for 1.75 to 2.25 silicon foundry, but no sales are noted at this price.

Transactions on the New York market are principally in resale iron and these sales usually consist of not more than one or two cars each. Buffalo foundry has been resold during the past week at prices ranging from $38 to $42 Buffalo for 1.75 to 2.25 silicon grade.

In the Cincinnati district one furnace which has been out of blast has been relined and is again working.

The disposition seems to be not to produce iron at the present high costs. The Jenifer furnace has been blown out, which further reduces the output. A little tonnage is being offered by an independent furnace company for $38 for No. 2 foundry, but the majority of furnaces are holding the price at $42.

Scrap Metal Market

Sharp drops are noted in many districts in the scrap metal market, but the general opinion is that it has nearly reached the bottom and that after another dollar or two decrease it will settle to a definite level. Ten thousand tons of heavy melting steel, recently sold at $19.50, delivered Chicago. Consumers are taking practically nothing and quotations are largely nominal. Railroad offerings are moderate.

After a remarkable record throughout the summer, continuing after all the other grades had softened, No. 1 machinery scrap at last has dropped in the Boston market. During the week the situation changed from a small supply to a surplus which accounts for the drop of $6 and $8. The fallen market seems to have brought some new business. Several hundred tons were bought at $33, del.

Prices in iron and steel scrap have declined from $1 to $3 in practically all grades. Rerolling rails city wrought and stove plate have dropped from $2.50 to $3 a ton.

Heavy melting steel has declined and is now holding at $14 to $15 f. o. b. New York. Clean cast borings and machine shop turnings remain unchanged, as these materials are not accumulating as fast as most of the others.

On the Pittsburgh market the actual quotations are largely nominal and unchanged from those of a week ago. Small lots are available at from $3 to $4 a ton lower, but these represent surplus quantities that consumers have on hand and are trying to dispose of, apparently with very little success.

On the Buffalo market the price of scrap is still declining, with few sales being made. Many cancellations of old orders have taken place and some dealers are overloaded with stock as they failed to gauge the market correctly and kept on buying. Most grades show a decrease in price over the past week and heavy melting steel is now quoted at $19 to $20.

Sharp declines have taken place in the steel scrap market this week at Cleveland, owing to an absolute dearth of business.

The general impression is that the market is still far from the bottom and as a result cancellations are numerous. Heavy melting steel is down from $21.50 and $22 to $19 and $19.25, and other grades are similarly cut.

The market continues extremely dull at Cincinnati. Surpluses have been accumulated in some yards and this is largely responsible for the price slump.

On the St. Louis market re-rolling rails have been marked down from $22.50 to $20.50, compared with a price of $40 on September 12. Reductions, however, have failed to stimulate buying. Consumers are more interested in cancelling orders than acquiring new tonnages.

PERSONAL

W. H. Fairchild, city engineer of Galt since March, 1916, has handed his resignation to City Clerk McArney, to take effect December 31. When interviewed officially he gave no reasons for his action and said he had no plans for the future. During Mr. Fairchild's term of office, Galt launched its permanent paving programme and he has supervised construction of all the pavements laid to date. Citizens generally have been well satisfied with his work. It is understood an effort will be made to retain him.

On behalf of the office staff of the John Morrow Screw and Nut Company, of Ingersoll, the presentation of a handsome electric reading lamp to Mr. George Duncan, of Hamilton, of the company's sales force, took place at the office. Mr. Duncan, who formerly resided there, has been in the employ of the firm about fifteen years. He has severed his connection with the company to accept a position at Buffalo, being associated with J. Anderson Coulter, who recently purchased the plant of the Curtis Screw Company of that city.

Efficient Automatic Machine Tool Records

An Automatic Machine Operator Should Be Provided With Suitable Charts to Enable Him to Change His Sets-ups Quickly. —Skeleton Set-ups on Turrett Chucking Lathe Are Explained.

By F. SCRIBER

TO enable automatic machinery operators to work on something better than a hit or miss plan in changing from one job to another, it is becoming more and more the practice to provide the operators with suitable charts or descriptive matter to enable them to quickly change their machines from one set-up to another, that is to say, that they can change from one class of work to a different class of work by following a sequence of set-up instructions and setting up the machine by scale measurements and also to arrange the proper feeds which will enable them to start cutting on the work set up with some degree of surety that the work being done will be very near to what is wanted and that the machine will be operating at practically maximum capacity.

An analysis of a turret chucking machine set-up which shows in some detail how this can be accomplished is the subject of this article. It is of course apparent that definite types of machines require somewhat different analysis even though they do the same class of work.

Referring to Fig. 1, we have a plan skeleton view of the actual set-up members on a turret chucking lathe; this shows a chuck A, the turret has four sides or faces B and the cross-slide carries a rear block for tools C, and a front tool block D; various dimension lines are shown in this view with dimension and indicating arrows referring thereto. The purpose of this is that with a given piece of work gripped in the chuck an operator of this machine can set his cross-slide from the chuck to a figure say 1¾ inches, as given, and can then locate his first turret face to the dimension 17 inches given. Likewise he can set the blocks on his cross-slide to the dimension 8 and 29 inches, which is shown, and then these various units will be in the correct cutting relation to the chuck for the work in hand.

The first part of this tool-setting description refers to locating the headstock carrying the chuck with relation to the turret as in this particular type of machine the headstock is adjustable lengthwise. Reference is also made here to change gears in the following terms: "Use change gears as shown in diagram," and a diagram of these change gears mentioned is shown in Fig. 2, where it will be noted that the number of teeth in the various change gears is supplied in places provided for that purpose X and Y.

The train of gears to be used is indicated by a check mark, while the feed change gear Z also has to be determined for the particular job in hand. To the right of Fig. 2 is shown a special gear having a thread on it which we will assume is to be machined at this time, but before proceeding with the machining of this gear it is first necessary to set the tripping dogs for controlling the movement of the turret and the cross-slide,

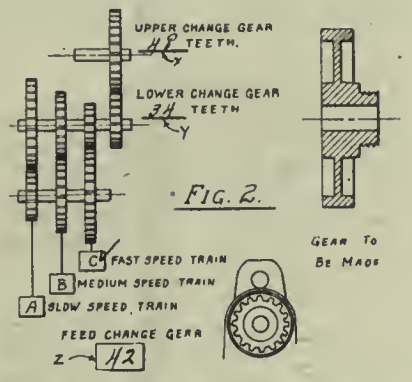

FIG. 2—SHOWING DIAGRAM OF CHANGE GEARS.

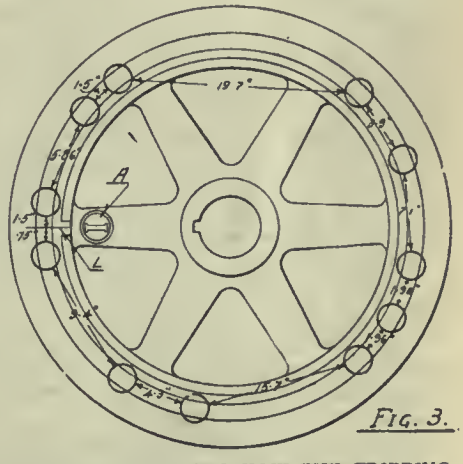

FIG. 3—ILLUSTRATING HOW THE TRIPPING DOGS CAN BE SET AT DEFINITE DISTANCES.

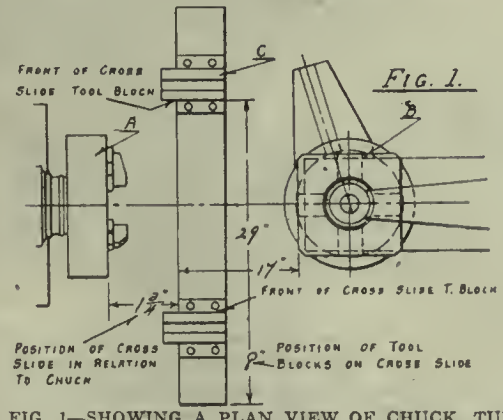

FIG. 1—SHOWING A PLAN VIEW OF CHUCK, TURRET AND CROSS SLIDE WITH NECESSARY SET-UP INSTRUCTIONS.

TOOL SETTING

To set tools, first loosen spindle headstock strap screws, thus allowing headstock to move longitudinally. With turret in forward position, bring headstock and cross slide to measurements given.

Headstock strap screws can then be tightened.

If it is necessary to revolve turret by hand, stop the turret slide at extreme return stroke. Use change gears as shown on diagram.

After this is done set the tripping dogs to suit the conditions.

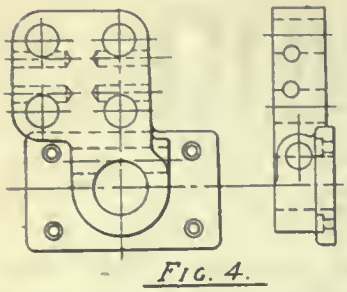

FIG. 4—ILLUSTRATING TYPE OF HOLDER DESCRIBED IN TEXT.

this being referred to in the lower portion of the tool-setting memorandum in Fig. 1.

To set these tripping dogs another diagram is provided, this diagram illustrates how, by starting at a point A the dogs may be set definite distances apart around a circle as indicated by the small circles S and F, to trip the various turrets and cross-slide operating member at the proper time. Having set the machine up as called for in these diagrams and shown by the first three illustrations we are now ready to consider the accurate setting up of the tools for machining this special threaded gear, but before proceeding with this it is perhaps better to note that a tool holder can be attached to each turret face which has in addition to the centre hole three or four other tool carrying holes, an illustration of this holder is shown in Fig. 4.

Fig. 5 shows a blank diagram suitable for use with this holder where it will be noticed that on the centre line A at the right are the words No. 1 turret face, and below this at the centre on line B, No. 2 turret face; there is a note at the top of this diagram as follows: "These numbers refer to the holes in standard tool-holder on turret," these being numbered 1, 2, 3, 4, and the purpose of these will be obvious by referring to Fig. 6.

This diagram is made for a machine having five turret faces. By referring to the gear-drawing, Fig. 2, and referring to the successive set-ups in Fig. 6, it will be noted by following the reference letters that on the first turret face A, Fig. 6, we have a spotting drill. At B we have a drill with facing cutter and two turning tools located in the holes 1 and 3 of the holder; at C we have a special boring tool in the centre hole and two turning tools in holes 1 and 3 for finish-turning the work. At D we have a reamer which is used for finishing the hole and at E is provided a threading die for threading the hub of gear, all of these tools are set up to the dimensions given from the various turret faces of the machine and are quite accurate, so they will locate the tools in the proper cutting position for finishing the gear, although it is usually necessary to take some trial cuts to obtain accurate work.

It will be apparent by following out this sequence of operations that a great saving of time will be had with much less setting up time and with less spoiled work than would be the case if the operator had to work by cutting and trying out each tool as he proceeded with his set-ups. While this plan is by no means new it is not so broadly used but what a good many variations of this general plan will readily suggest themselves.

BRASS ITCH

One of the most interesting of the occupational diseases, and one about which but little has been known as yet, is the result of brass poisoning. The matter is quite satisfactorily treated by Dr. R. P. Albaugh, in a recent issue of Modern Medicine.

The symptoms are exhibited for several hours after exposure to the fumes from molten brass or zinc. They start with a dry, parched thirst, an irritating and unproductive cough, a feeling of constriction in the chest, lassitude and anorexia—which latter is simply loss of appetite—often followed by nausea and vomiting; a headache sometimes develops and chilly sensations are noticeable within one to four hours. The chills rapidly verge into a distinct rigor which lasts from one and one-half to two or three hours. The application of warm clothing or external heat seems not to diminish the rigor of a chill. Muscular cramps and sharp pains in the joints usually accompany the chill. The symptoms end rather abruptly, almost by crisis, and are followed at once by a profuse perspiration. The patient will probably fall into a deep sleep following the stage of relaxation and without any apparent ill effects.

Brass poisoning does not occur from handling of the metal or the zinc alloys which go into its composition, but is limited to those exposed to the inhalation of the whitish smoke and sublimation products from the molten metal.

There is no specific treatment for brass poisoning, "brass itch" and "brass chills." Zinc is supposed to be responsible for the bad effects. The affection was formerly confused with malaria. Some workmen find relief in drinking hot milk to which pepper is added. A good purge also seems beneficial. Dr. Albaugh advices the prevention of brass poisoning by better hygienic arrangements in foundries and smelters, elimination of careless habits of workmen and large, roomy quarters.

SAFETY IN THE MACHINE SHOP

In connection with its efforts to reduce the number and severity of industrial accidents, the Travelers' Insurance Company, Hartford, Conn., has recently added another book to its accident-prevention series. This new publication is entitled "Safety in the Machine Shop." It contains 188 pages, six by nine inches, and is bound in paper covers. It is a splendidly arranged book dealing with the various phases of the safety problem as encountered in machine-shop practice.

The book is divided into fourteen sections, the first of which sketches the development of the machine shop from the time such an establishment consisted of the proprietor and one or two assistants, up to the present-day shop employing thousands of persons. In the remaining sections the safety problems that arise in the modern shop are discussed in detail and careful consideration is given to cranes, lathes, automatic machines, grinding apparatus and other machine-shop equipment. In addition to the discussion of safeguarding, and safe-operating methods, subjects indirectly related to accident prevention are considered. One section treats of "Infection From Cutting Oils" and another deals with the subject of proper illumination and its bearing on the accident prevention problem.

These and other special features will undoubtedly be of interest to machine-shop proprietors and to other persons concerned in accident-prevention work. This book will be sent without charge to anyone making request for it to the supply department of this company.

FIG. 6—ILLUSTRATING THE USE OF THE DIAGRAM.

Western Branch.—The Gordon MacLay building at Brandon, Man., has been purchased by the Massey-Harris Company, Ltd., at a purchase price of $130,000. A large distributing plant will be established there in the spring.

Do Machinists Correct the Mistakes of Others?

Drive Problems Are Often Misunderstood—Electricians Are Not Machinists, Therefore Should Stick to Their Own Trade—The Repair Man is the One Who Suffers.

By DONALD H. HAMPSON

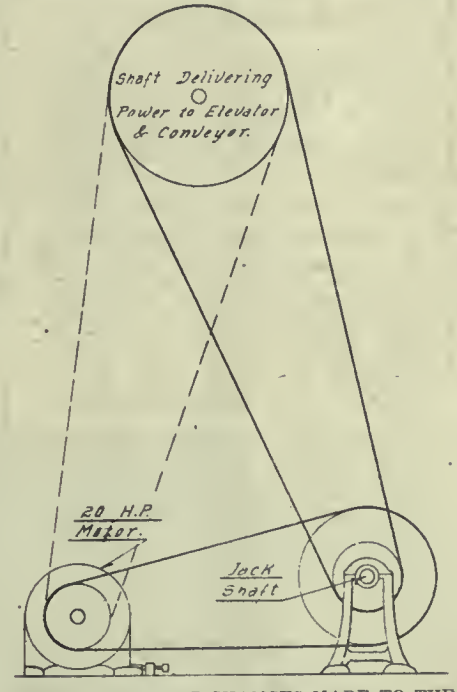
IT IS human to make mistakes; machinists make as many as any other class of workmen, while those machinists in the repair business are called upon to correct more of the mistakes of other workmen than men in any other calling. We learn more from mistakes than we do from direct instruction, probably because the thing is visualized right before us in all its glaring error. A number of mistakes innocently made by electricians will be cited.

The Gordon Coal Co. had a big elevator plant with a vertical bucket line taking coal from the track pocket and delivering it on a horizontal chute above, whence it was conducted to the proper bins for that size of coal. This machinery had been run for ten years by a 20 h.p. gas engine and had given satisfaction except for an apparent loss of power during the last couple of years. Naturally it was concluded that the engine needed a little attention—just cleaning and tuning up, for the work of unloading three cars of coal a week had been no tax upon the wearing qualities of any part. The people who had sold the engine were very indifferent in the work they did when called upon, with the result that the Gordon Co. in their inexperience came to the conclusion that the outfit was worn out.

At this juncture a couple of telephone electricians who were starting in the wiring business for themselves heard of this opportunity and induced the coal company to buy an electric motor, which the boys proceeded to instal very nicely. They placed the motor pulley in the same plane as the old engine pulley, driving with the same belt to a four-foot pulley overhead. Apparently, the item of speeds did not occur to the electricians or, if it did, they concluded that the reduction from twelve inch to the nine inch pulley on the motor was quite sufficient, not taking into consideration the fact that their motor ran at more than three times the speed of the gas engine.

When they finally got started, the belt slipped so that it would run off the motor pulley. By shortening it till it was as taut as a violin string, they made it stay on and the bucket chain began to move. It looked fine and the coal people remarked that their elevator system had more pep in it than it had shown for years. There was no coal being moved just then—due to one of the numerous schemes that are enacted to jack up the price—and the house could do nothing else than pay the bill for what looked like a good job well done.

Some weeks later when a car did get through, it was found that the conveyor could not be started with coal in the track pit. After shovelling this out and dumping in a limited amount from the car at a time, the load was successfully distributed. The electricians had been called in and they concluded that the speed was too high so they had the motor pulley reduced an inch and a half and took another piece out of the belt. The next car was unloaded in about the same manner, but not until the belt had been again shortened, and in trying to unload the car in less than five hours the pit was allowed to fill—just as in



HERE WE SEE THE CHANGES MADE TO THE DRIVE.

the old days with the gas engine. It was stove coal this time and how that chain and buckets did rasp through the pile! Six buckets ripped off and several links bent—bent so badly that they jumped the sprockets.

Machinists repaired the damage. Asked to report on the causes, they stated that the speed was entirely too high. When taking material from the side of a pile or when the material is dumped into a horizontal chute, almost any speed within reason may be employed, but when buckets must be forced in and through a compact mass at the bottom of a vertical run, the speed must be slow for commercial types of elevators to stand up at all. In this case a countershaft was interposed that reduced the surface speed from over 150 to 50 feet per minute—which is a safe maximum for such work. Better to have a mechanism which can do its work without injury and be always ready to work, better to fill each bucket every time than to bend and tear off one every time the outfit is used—this is better than a few minutes saved while the outfit is running to be followed by a protracted season of tinkering. And this is true of many things besides coal elevators.

In this case, the machinists changed the motor pulley to a size larger than the original—both to get greater adhesive surface and to lessen the bending of the belt as it passed around it, the latter being two-ply. The drawing shows the changes made. It shows also how a means was provided of taking up on the belt without cutting it every time, which had to be done when the drive was overhead. The changes proved all that could be wished. If the electricians had given thought to speed or had consulted anyone who understood this and the best practice with belts, they would have saved themselves and their customer much expense and protected the reputation they were trying to build. And this information could have been obtained gratis; workmen in one line are only too happy to help others who occasionally encounter problems in that line as a sort of side issue to their own particular field of work.

The Double Belt Fallacy

Departing for a moment from the original purpose of the article, a point in connection with the instance just recorded applies with equal force to other belt problems, i.e., the use of double belts. The motor drive named was through a double belt to the first pulley and that double belt had to form itself around that small motor pulley running at a high rate of speed.

The writer is firmly convinced that a double belt should never be used on any pulley under 18" and better not under 24", for the reason that on smaller pulleys the normal surface speeds at the inside and outside of the belt where it passes over the pulleys differ so greatly; it may be that there is a difference of 10 per cent. If the two plys were separated—not cemented together—and could be made to run that way, the difference in speed could be plainly noted, but they are not, and so the belt must stretch and slip and buckle as it curves around the pulley. What this does may be imagined. Very soon the cement bond is broken here and there and we have

two belts, somewhat stuck together, but neither of them pulling half the load as they go flip-flopping around before final separation.

To show what double belts will do on large pulleys, a certain plant put in three 8" double leather belts nineteen years ago as a means of transmitting 16 horsepower from the engine room to the machine shop. The pulleys on the shafts are all 48" and travel at a surface speed of 1800 f.p.m. To-day those same belts are transmitting 30 to 35 h.p.—they have been treated three times, the stretch taken out twice and there is no sign of a separation of plys. Contrast this with a drive the writer was asked to improve recently. The "electric light gang" had installed a motor in place of a steam engine to drive a blower in the city gas plant of the same company, the installation being a 10 h.p. motor with 8" pulley driving to a 6" pulley on the blower through a double belt. It had been a new belt, first class, and it had slipped so well that the friction had heated the inner ply, loosening it and forming it in puckering waves all around the inside. A double belt had been used because of the generally known fact that "they transmit more power and stretch less."

The writer admits to having been sold on the "more power" point of the double belt, and learned by bitter experience the falsity of it. A grinder with 6" pulleys was so equipped, and, as the belt was the best that money could buy, we concluded that the purchase of a new one every six months was a necessary expense that could not be avoided. It was not until a "drummer" (as they called them then) came along with one of the early woven cloth belts that we learned our mistake. This sample belt, at half the cost of the leather one, lasted five years—simply for the reason that it was soft enough to hug the pulley throughout the entire arc of contact and hug it so closely that it did not slip. The moral is: if you have a hard drive and the pulleys cannot be enlarged, use wider faced pulleys and a single belt in preference to narrow pulleys and a double belt. To make the point clearer by going to an extreme, just imagine how much power a pulley would deliver to a belt made of sole leather.

Returning to the subject of electricians, the boys had secured a job to motor equip the machinery in a food product plant, including the can and bottle washing machines. Somewhere they had picked up a number of 140-tooth gears which they were putting on the can washers, driving the gears through 9-tooth pinions on the motors. They went to a local shop to get the 9-tooth pinions made. The shop protested, giving their reasons as the weak teeth and the extra noise as well as a 9-tooth gear being less than standard; but they finally made the gears on a "no responsibility" basis. And in a few short months the pinions were done for, being replaced by worm drives of similar reduction. In this particular case a standard, based on theory and practice, was disregarded as a matter of little consequence—but men in every craft are apt to hold lightly the restrictions of another, so the electricians cannot be too severly censured.

The Roe Brothers firm had the only coal business in the village of Florida—progressive men who early established a coal elevating plant run by a steam engine, changing later to a gasoline engine, and finally to an electric motor as these prime movers were developed. Their motor drive was an entirely different arrangement from that of the elevator previously mentioned; in this case the motor was installed on 4 x 6 beams up near the roof, driving through two gears a length of shaft from which the bucket lines took their power. One gear, a 10-inch steel pinion of two and a half face, was on the motor shaft—it meshed with a gear on the shaft which latter was supported by hangers bolted to the same 4 x 6's. The motor was of ample size for the work. Its speed was 1200 r.p.m.

Well, any mechanic can picture in his mind what happened to that soft steel pinion delivering 15 h.p. at 1200 revolutions. The teeth were strong enough from a theoretical consideration but there was not width enough to distribute the load over an amount of surface to insure long life. The pinion wore out in three months, and not three months of steady running either. Mr. Roe brought his worn pinion in to us to make a duplicate just as quick as we could hustle it out aided by telegraph and express in getting a blank.

About three months later he came in again on a similar errand. This time our curiosity was aroused and we obtained the features of his engineering layout. The worn gears showed that the centre distances were too far apart to have the teeth mesh proper depth and our questioning brought out the point that the shafts spread apart when the load was applied, though they were close enough together under the friction load only. We guessed (aloud) that the beams sprung and that the hangers on the shaft were not rigid enough. Our suggestion was to move the motor farther away, substitute sprockets for the gears, and use a silent chain drive. The suggestion met with favor, but, of course, could not be carried out in a hurry, so we made another pinion, this to be carefully installed and the beams strengthened and the gears well lubricated.

A month later our Mr. Roe 'phoned to order the chain and sprockets at once because the new pinion was wearing and the gear also was in bad shape. Luckily the new parts came before the gears gave out altogether, and after being duly installed they ran for years and years without giving any trouble, and are running yet with entire satisfaction.

It was a case of the electricians not knowing the ill effects of high surface speed on soft gears, too narrow to wear under the most favorable conditions and in the gritty atmosphere of the place subjected to unusually rapid abrasion. Then gears at this speed should run constantly lubricated and they should be fully in mesh to insure perfect rolling contact. The substitution of the chain was the employment of a device especially designed for high speeds, long life at those speeds, and with an entire disregard for minor changes in the centres.

MORE POWER

When you have a hard drive and your pulleys cannot be enlarged, use wider faced pulleys and a single belt in preference to narrow pulleys and a double belt.

Be sure that when you install gears, the surface speed is not too high, and above all see that the centre distance are correct. If the atmosphere is dirty and gritty, decide to lubricate the gears.

Another point to remember is this: Many a drive has been improved through the substitution of a chain in place of the gears. These are a few of the lessons contained herein.

NEW LINE

The National Electro Products, Ltd., Toronto, who are at present manufacturers of electrolytic oxygen and hydrogen by an electrolytic process, have added still another line, namely that of Purox equipment. This line includes a complete range of oxy-acetylene and oxy-hydrogen welding and cutting torches, decarbonizing and lead burning outfits, gauges, regulators, hose, goggles, welding rods, fluxes, etc. This is a new line in Canada but has been used in the United States for the past five or six years. The first time this line was shown in Canada was at the Toronto Exhibition, and they drew favorable comment at this time.

GIVE CREDIT

In the November 4 issue of Canadian Machinery there appeared an article on Turret Lathe Practice as adopted at the plant of the Foster Machine Co., Elkhart, Ind. In this there were drawings and portions of the reading matter which should have been credited to "Machinery," New York. We regret that at the time of publication there was omission of these credit lines to our American contemporary.

The Manufacture of High Speed Tool Steel

The Crucible and Electric Furnace Methods of Producing Steel —The Base Materials Must Be Carefully Selected to Obtain a Satisfactory Product.

THE manufacture of iron and steel is always a very interesting subject, but the story of tool steel is even more fascinating. At least such proved the case at a recent meeting of the Toronto chapter of the American Society for Steel Treating, when Mr. Cremp, metallurgist for the Canadian Atlas Crucible Steel Co., Ltd., Welland, Ont., gave an illustrated talk on "Modern Methods of Tool Steel Manufacture."

The speaker was greeted by a very large number of men interested in steel treatment in its various phases, and embellished his talk with four reels of moving pictures, the first of these showing various views of the American plant, how they weighed carefully the various ingredients, placing the material in the crucibles, the heating of same, the pouring of the metal, etc.

The second reel illustrated the electric furnace method of producing tool steel, these views showing both three-ton and six-ton furnaces in operation. Various tests were shown, also the grinding of all surface defects before hammering.

The third reel was devoted to rolling work, also depicted annealing and straightening of stock. The last reel continued on this subject and illustrated various cold drawing operations, and other interesting procedure in tool steel manufacture.

The talk was so cram full of real up-to-the-minute data that the writer decided to get the details from the speaker, so that readers of Canadian Machinery who could not personally attend might get as near as possible the full benefit of the lecture. This he was able to do, so from now on let us imagine we are sitting back in our chair, listening to Mr. Cremp.

In considering the manufacture of tool steel it is very important that the process be not compared with the Bessemer or open hearth method. Those readers who are somewhat familiar with these various methods will know the great amount of hand labor necessary for a small production of tool steel. This is due to the fact that in tool steel manufacture the foremost thought has to be, or at least should be, quality rather than quantity.

It might be as well to define what I mean by tool steels, as the term is very broad. By the statement I mean all steels which are capable of being made into tools, and as such, and after suitable treatment, are capable of doing work upon other steels, metals or substances. This will include the simple carbon tool steels and all alloy tool steels. By simple carbon tool steels is meant steels which contain no elements other than silicon, manganese, phosphorus and sulphur and whose physical properties depend upon the carbon content only; the carbon content carying from 0.05% to 2.20%, depending on the use, but for most purposes between .75% and 1.35%. By alloy tool steels is meant steels which contain all of the above elements and in addition varying percentages of one or more of the following elements: tungsten, chromium, vanadium, cobalt, molybdenum, etc., in sufficient quantities to affect the physical properties of the steel.

Probably the chief requisite in any tool steel is uniformity in quality, both chemically and physically, for one must have both chemical and physical uniformity in a tool steel to obtain best results. Either may be individually perfect in a steel, yet that steel will fail when made into tools; and quite naturally it usually is the physical or structural uniformity which is overlooked. How often have all of us noted the case of two steels being identical in chemical analysis, yet one would make excellent tools while the other would fail miserably when made into the same tools? It is due to this absolute necessity of uniformity that tool steel has been limited to certain methods of manufacture for best results. In order to

A NEAT INSTALLATION OF ELECTRIC FURNACES USED BY THIS CONCERN.

THIS ILLUSTRATION DEPICTS A HEAVIER HAMMER JOB.

obtain this uniformity the method of manufacture must be capable of accurate control and for this reason the crucible and electric furnaces have met with best results and greatest approval.

As in other manufacturing processes, what are termed its raw materials are really the finished product of some other industry. So in the manufacture of tool steel few virgin materials are used, but rather the finished products of some other process. Thus are used various kinds of scrap steel, the products of the crucible, electric and open hearth steel processes; wash metal, the product of a special open hearth process; pig iron, the product of the blast furnace; melting or muck bar, the product of the puddling furnace; ferro-tungsten, ferro-chrome, ferro-vanadium, ferro-manganese, ferro-silicon, etc., all finished products of still other processes.

Selection of Base Materials

The selection of the raw or base materials is very important and only the very best are suitable for tool steel manufacture. This is especially true in the crucible process, where little or no refining can be done and the quality, that is quality as far as analysis is concerned, depends entirely upon the base materials used. As a result, all these materials are purchased on analysis, with special attention to their sulphur and phosphorus content, which two elements, as you know, are the greatest enemies in tool steel. It is, of course, true that a wider latitude of materials can be used in the electric furnace, but this should not be presumed upon. Too many have made the mistake of expecting to get first quality product from their electric furnace by using junk to begin with. This is not possible in the electric any more than in any other process of making steel, although, as above stated, the possibilities of refining are greater in the electric furnace than in any other. It is not a wise or an economical policy, for what is saved in the purchase of materials is more than offset by the extra time required to refine those materials and consequently decrease the production from the furnace.

We now arrive at the steel compounding and melting operation and will discuss the crucible process first. The various materials which constitute the base of the mix for the charge are carefully weighed out into trays. This consists of muck bar, various scraps consisting of crop-ends from ingots, billets and bars, as well as other solids of known analysis. Just so much of each different one can be used, depending upon its analysis and the result desired. The importance of care and accuracy in this step needs no comment, for, as before stated, upon the charge depends the chemical content of the product. In a separate room, technically known as the "medicine" or "dope" room, the alloys and other costly elements which largely determine the particular properties of the finished product are very carefully and accurately weighed out into metal pails. These are transported to the melting floor and there charged into the crucibles with the base materials previously described, the entire comprising what is called the "mix."

The crucibles used are manufactured from either clay or clay and plumbago, holding anywhere from 50 lbs. to 100 lbs. of material. A cap is now placed on the pots to exclude any furnace gases and is ready to be lowered into the furnace. In charging a furnace a person known as the "puller-out" (for he pulls out as well as sets-in) grasps the pot in a pair of tongs and lowers it into the hole of the furnace. The construction of the furnace is such that six pots can be placed in each hole, the total capacity of the furnace depending on the number of holes. The various sized furnaces are usually spoken of in terms of pot capacity as a twelve, twenty-four or thirty-pot furnace. These furnaces are of the regenerative type, having two sets of checker chambers underneath. The object of regenerators or checker chambers is to preheat the incoming air and gas, thus building up the temperature in the melting hole. Either producer or natural gas can be used.

In melting down the charge the direction of the incoming gas and air is reversed at regular intervals. By this reversal of direction the exhaust gases are made to flow first through one set of checkers and then through the other, giving up their heat to the brick in passing, which in turn is reabsorbed by the incoming gases. The length of time required to melt the heat varies with the nature of the mix and the elements contained therein.

Two and one-half to three and one-half hours are usually required to melt the charge thoroughly, and it is then "killed," which requires about thirty minutes. This "killing the melt" is a term which applies to that portion of the process allowed to bring the steel to the proper casting condition and to permit any gases in the molten steel to escape. This, as well as the entire melting operation, is in charge of the "melter," who must be highly trained, skillful and reliable. The exact time for pulling a crucible heat is very important and definite and must be constantly watched, as a heat having too little fire will probably contain particles of undissolved alloys, and if allowed to soak too long after melted, or if carried to too high a temperature, the pots will be badly attacked and the steel will absorb more or less carbon.

The Puller-Out

At a word from the melter, the "pullers-out" proceed to pull the white hot pots containing molten steel from the furnace. These men must necessarily be of exceptional physique, experienced and steady nerve. They prepare themselves for their work by removing all of their regular clothing and putting on special clothing, wrapping their limbs in burlap and donning "clogs," which are very heavy shoes shod with wood and iron. In order to remove a pot from the furnace it is necessary for the "puller-out" to step directly over the hole, reach down into the furnace, whose temperature is approximately 3000 deg. Fahrenheit) and grasp the pot. This is no easy task, when it is remembered they contain close to 100 pounds of metal besides their own weight; in all,

probably 120 to 140 pounds. Special tongs are used for the purpose.

As the pots are pulled from the furnace they are delivered to the melter, who in turn empties them. It is at this point that different manufacturers of crucible steel differ. Some proceed to pour the contents of each pot individually into molds whether casting small or large ingots, while others first teem all the individual crucibles into a ladle and then proceed to cast their ingots from this ladle. In my estimation there is little comparison between the two methods as far as obtaining uniformity of product is concerned. In the first method you are apt to have as many different analyses as you have pots where single pot ingots are cast, and where large ingots are cast the casting must necessarily be more or less intermittent. Outside of a few improvements in construction and handling, the entire process of crucible melting has changed but little since its first introduction by Huntsman in 1740.

Electric Furnace Method

The electric melting process is spoken of as being acid or basic, depending upon the nature of the lining in the furnace. If the furnace is operated under acid conditions, the lining is of silica brick and sand; if under basic conditions, it is lined with magnesite brick and magnesite or dolomite. Whether it is operated acid or basic depends upon the result desired. The reduction of sulphur and phosphorus and especially the latter is more easily accomplished by the basic process. As these are most objectionable to tool steel, most electric tool steel furnaces are operated on the basic principle.

In this case, instead of weighing out the raw material in 90 or 100 pound lots, the entire furnace capacity is weighed up as a charge. This charge, be what it may, ingot crop-ends, punchings, boiler plate, flashings, tubing, etc., is charged by hand into the furnace. Upon the completion of this operation a certain amount of lime and slag-making material is charged into the furnace, which is the chemically active portion of the bath and upon it depends the amount of refining that is accomplished. The entire charge is now ready to be melted down and the current is applied. The current, or "juice," as it is commonly known to the men, is usually about 100 to 110 volts, the amperage consumed depending considerably on the type of furnace and the operator using it. The usual consumption per ton of liquid steel is about 500 to 650 k.w. when starting from a cold charge. The melting down operation, that is, bringing the entire charge to a molten condition, requires from 1½ to 2½ hours.

At this point a test or preliminary sample of the bath is taken and sent to the laboratory for analysis. While awaiting the report, which takes from twenty minutes to one hour, depending on the type of steel, it is generally necessary to pull a slag. During the melting down and before the temperature of the bath becomes too high, certain impurities in the charge, and especially phosphorus, are taken up by the slag and held as long as the slag is basic. As the temperature increases and the old slag remains in contact with the bath, it has a tendency to become acid or at least less basic, so it is usually advisable to remove this slag and put on a new one.

The period which has just elapsed in the electric melting process is technically known as the oxidation period, during which the phosphorus is removed. The second period is known as the reduction period. A strongly reducing atmosphere is maintained throughout this period as well as a strongly basic slag, the object being the elimination of sulphur. The length of time necessary depends upon the degree of desulphurization required. It may even be necessary to pull one or more slags. It is also necessary, during this period (in order to hasten chemical action) to maintain a higher temperature than during the first period.

Bringing to Proper Analysis

As soon as the laboratory reports the results of the preliminary sample, the melter proceeds to make whatever additions are necessary to bring the liquid steel up to proper analysis. Here is a distinct advantage of the electric furnace in making steel; absolute control of the temperature and analysis at all times. Even if some error has been made in the original calculations or weighing up, upon receipt of the preliminary report this can be corrected. As soon as the additions have become thoroughly melted and uniformly distributed throughout the bath by frequent and sufficient rabbling, the molten metal is "killed" or deoxidized as in the crucible process. The correct pouring temperature as well as the condition of the metal is determined by pouring small test ingots or blocks. At a signal from the melter the entire furnace is tilted and its contents poured into a heated ladle. From the ladle the steel is cast into molds as in the crucible process.

The liquid steel, made by either process, is now cast into molds, which are usually square or hexagon in shape, these molds being made of cast iron. Small molds such as are used for tool steel work, say 3½ in. square, up to 12 in. or 14 in. square are usually split with a solid bottom, and when in use are fastened together with rings and wedges. The object of using split molds is the greater ease in removing the cast ingots and also greater ease in smoking the molds, which operation is neces-

GRINDING OUT THE DEFECTS. EVERY FLAW MUST COME OUT OF THE BILLETS BEFORE THEY ARE PASSED.

sary to keep the liquid steel from sticking to the sides when casting. Considerable care must be exercised on the part of the molder in preparing and setting up the molds to see that they are properly aligned and plumb. If they are not exactly perpendicular the metal, when flowing from the ladle into the mold will stick on the sides or splash, producing rough and bad ingots.

The ladles are usually of such capacity as to hold the entire heat, and consist of a metal shell which is lined with fire-brick. In the bottom of the ladle is a hole into which a clay or graphite nozzle is fitted, the size of which varies with the size of the ingots being cast. This nozzle, through which the liquid steel flows, is opened and closed by means of a rod on the bottom. The stopper, as the entire rod and stopper is called, is actuated by means of a handle hinged on the outside of the ladle.

transported to the annealing department. Not all ingots are annealed before working, but high-speed and certain other alloy steel ingots should be. After the ingots are loaded into the furnace they are slowly brought up to the annealing heat and then allowed to soak at this temperature. The operation is not so much to obtain a soft ingot, although an annealed ingot will work softer than one which has not been annealed, as it is to remove the cooling strains of the ingot and to allow the internal structure to rearrange itself. After they have soaked a sufficient length of time the firing of the furnace is stopped, and the furnace and ingots are allowed to slowly cool. When they reach a temperature below a black the ingots are pulled out and passed on to the first inspection and grinding department. The entire annealing operation requires about twenty-four hours.

AN EXAMPLE OF LIGHT HAMMER WORK.

Obtaining perfect cast ingots is of the utmost importance to the tool-steel maker, and is his first great source of difficulty. I mean by perfect ingots, ingots which are free from pipe, segregation, blow holes, fins, rough surfaces, and a hundred other objectionable imperfections which render the ingot wholly or partially useless. It is a well known fact that in order to obtain good finished material, it is absolutely necessary to start with good ingots. Piping is one of the greatest, and certainly the most noticeable difficulty encountered in the ingot. Pipe is the term which is applied to designate the shrink cavity which forms in the ingot as it solidifies.

Annealing the Ingots

As soon as the ingots have cooled sufficiently so that when tipped over they do not bleed, the rings are knocked down and the ingots stripped. They are then

The inspectors carefully go over each individual ingot and mark with crayon any seams, cracks, or surface imperfections which might develop into larger imperfections in the billet. The grinder operator now takes the ingots and painstakingly grinds out all places marked by inspector. This is an expensive, and to many, an unnecessary operation, but experience has shown that with certain types of steel, too much care and caution cannot be exercised, as surface defects never grow smaller but always work larger in subsequent operations.

Chemical Analysis

It is at this point in the progress of the ingot that drillings are taken from every heat of ingots and sent to the laboratory for complete chemical analysis. The laboratory must be in charge of an experienced and reliable chemist whose only duty is to report accurately every element determined. A complete report of every heat of ingots is made, and if the content of each element does not come within certain specifications the heat is scrapped immediately. The specifications for different grades, of course, vary with the use for which they are intended, but in each case must be rigidly adhered to. It is also important and absolutely necessary in order to avoid error that no material should be applied on orders until a complete analysis of the heat is at hand. It is the frequent case in many mills that certain ingots are applied on orders on expected or hoped-for analysis, but this is poor policy as too often your hopes are wide of the mark.

The analysis being approved, the annealed and ground ingots are now ready for the cogging hammers and are transported to that department where they are charged into the reheating hammer furnaces. The firing is started, and the bringing up to forging temperature is carefully and slowly accomplished. With each hammer is the hammer crew, consisting of hammer, man and helper, hammer-driver and lever men, in each case named after the duty performed. The hammerman is in charge of the gang and is responsible for the work done, frequently working on a contract tonnage basis and hiring his own men. He must be a man of experience and know exactly how high to heat each different grade of steel, within what limits of temperature each grade of steel will forge without disaster, and just how much reduction they will stand. The size of the ingots must be properly proportioned to the different sized hammers, or correct results cannot be obtained. Overheating and bursting are two of the greatest difficulties encountered in this department.

The average hammers used in tool steel mills range in size from 1,000 pounds to 12,000 pounds and are steam driven. Steam and hydraulic presses have been experimented with on tool steel to a considerable extent, but in general have not met with best success, the action being rather more drastic than most tool steels will stand and especially high alloy tool steels. When the ingot has reached the correct temperature, which is measured by a pyrometer, it is taken out of the furnace, placed under the hammer and reduced to what is known as a billet. A certain amount of the pipe end of the ingot is cropped off at this stage, depending upon the soundness of the ingot. This is known as the crop end and will amount to 10 to 20 per cent. of the ingot weight. Another appreciable yet frequently overlooked loss starts to assert itself with the heating operations on the ingots and billets. This is the loss due to scaling. Few would believe that this loss alone amounts to 10 to 20 per cent. of the weight of the ingot. Neither of these are total losses by any means as both are kept separate according to the grade

of steel and returned to the melting department where they are remelted and start their journey over again. The amount of reduction varies with the result desired, but usually runs about 65 to 80 per cent. in area. This entire operation is called cogging. In fact, every operation of reduction, whether on the hammers or rolling mill which does not produce the finished size is called a cogging or recogging operation.

The cogging or forging operations have more for their object than the mere reduction to the size and shape. The steel as it exists in the ingot is in a very unrefined and coarse crystalline condition, with the carbon content and other elements more or less segregated according to their solidification temperatures. The forging operation tends to uniformly distribute the various carbide segregations by breaking up the large, weak crystals of formation and producing a refined, uniform structure throughout. In order to accomplish this objective it is necessary that sufficient work be put upon the ingot and at a proper temperature.

The billets are once more taken to the inspection and grinding department, and if of a type of steel which makes it advisable, they are annealed. The inspecting and grinding of the billets is carried on in exactly the same manner as described for ingots. There are certain types of steel which can be chipped with air chisels. On this material it is easier to chip the imperfections out than it is to grind them.

Rolling

The ground and inspected billets are now delivered to either the hammers or the rolling mills as the case may be for recogging or for finishing. The recogging would be carried out just as previously described in the cogging operation. If the work is such that it can be done on the mill, it is advisable to do so as their work is much quicker and more accurate. On a mill the reduction and working is brought about by passing the billet back and forth through grooves in rolls. Each succeeding groove is slightly smaller than the one previous, and in this way the billet continually decreases in cross section and increases in length. The shape and succession of the different grooves for efficient rolling is a unique science in itself and must be laid out so that the material is not burst, seamed, lapped, or scratched in any way. A mill is always designated according to the diameter of its rolls as a 10 in. mill, a 14 in. mill, these meaning a mill having 10 and 14 in. rolls respectively. Most mills are built with rolls three high and driven in such a manner that the material is fed through one way between the bottom two rolls and back through the top rolls. The length of a train of rolls is spoken of in so many stands as five, six, or seven stands. The different sets of rolls which make up the stands are known as roughing rolls, strand, leader and finishing rolls, according to the shape of the grooves in them and the duty performed. The mill forms a very efficient and rapid means of working steel and has many advantages over a hammer but must be in the hands of a competent roller to produce the results desired.

Great care must be exercised in setting up the mill to get everything in alignment and have the work pass through smoothly. Not only rounds, but squares, hexagons, octagons, flats and many remarkable shapes can be rolled on a mill, one of the principal advantages being that once the mill is set up and the size and shape found to be correct, any amount of material can be put through, and it will all be exactly alike. The greatest difficulty encountered is the time lost in changing rolls to meet the different sizes and shapes. Consequently it is advisable to segregate all the rounds, squares, and flats and roll them at once while the mill is set up. This partly accounts for the reason why sometimes when an order is placed with a mill the delivery seems unreasonably long, while at other times most extraordinarily short, all depending on whether the order arrived just after or just previous to a rolling of that size and shape.

The ingot has now arrived in its finished shape and size and is known as a hot rolled or hammered bar, but is still in a condition not suitable for most uses. The bar is still in a raw condition, ununiform and quite hard; structurally it is in a sorbito-pearlitic condition. In order to put it into a usable condition it must be annealed; acordingly, the raw hot-rolled bars next go to the annealing room. Here they are packed into tubes with some material such as charcoal and ashes, lime, sand, etc., and the ends of the tubes sealed with fire-clay. Some manufacturers do not pack their material for annealing but its use seems very desirable and beneficial. First, it causes the heating to be slower; second, it tends to a more uniform condition throughout the entire bar, and third, it causes the cooling down of the bars from their annealing temperature to the slower, all of which are essential to good annealing.

The sealed tubes and their contents are now rolled into the furnaces, which are then sand sealed and the heat applied. The annealing temperatures are all carefully predetermined and controlled by pyrometers. The particular annealing temperature in each case depends upon the type of steel being annealed. The time of heating, time held at temperature and cooling must all be correctly worked out and varied according to the size and kind of bars. The usual annealing operation requires about twenty-four hours, and it is usually considered best practice to allow the tubes

ROLLING OUT THE BARS. THIS, OF COURSE, IS ON SMALLER SIZED STOCK.

and material to cool down below a black before removing from the furnace. The annealing operation not only softens the steel but it also puts it in a uniform and stable condition.

Final Inspection

The annealed bars are now removed from the tubes and go into the final inspection department. Here each individual bar is carefully gone over for size and surface conditions, a portion from each end is broken off so that the condition of the grain can be examined. From this examination can be learned whether or not the annealing has been correct, whether the bars have been decarburized in the mill or in the annealing, and whether the bars have any minute pipes or other internal imperfections. The man doing this inspection work becomes highly skilled and can pick out small pipes and imperfections which the ordinary person could not see. Here also several ends from every different lot of bars from each heat are taken and tested for hardness. By far the best method in my opinion for making this test is the Brinell, the principle of which is well known. Certain limits of hardness are established for the different grades and tempers of steel, and unless the tests come within these limits the material is rejected and reannealed. After the bars have passed this final inspection they are sawed, straightened, stamped, and bundled ready for shipment.

Due to the many different grades of steel, different shapes, and the thousands of different sizes, a very accurate yet simple system of keeping track of the material from the ingot to the finished bar must be worked out. Not infrequently a billet or two of one kind of steel gets into a lot of billets of the same size of another steel and probably will not be caught until the final inspection and sometimes not here if the only difference is in the temper, both being the same grade. Consequently, the entire process requires constant vigilance and attention in order to produce quality material, which every tool steel manufacturer should desire. By far the greatest part of the task of maintaining the quality of the product falls to the metallurgist as most everyone else is primarily interested in the production and are very apt to overlook many vital matters to accomplish that end.

He usually has at his disposal a well-equipped physical or metallurgical laboratory and capable assistants. I wish to particularly emphasize the vital importance and usefulness of the work which is capable of being done in this department. In the past it has been frequently the case that the physical laboratory has been more of a show place, or at best an experimental department, but in the present day demand for uniformity and quality in tool steel this department becomes a prime factor. One of his most useful friends in this work is the microscope. By the proper application of this apparatus he is able to control the internal structure of his product and is able to tell when things are not going right, and by making frequent observations of the ingots, billets and finished product he is able to keep the entire material lined up on a good basis.

FORM TOOL MAKING

By J. Homewood

WHEN rapid production of intricate formed faces on brass products is desired, at the same time maintaining uniformity of shape and size, the following adapter and attachments for an engine lathe are recommended. The material produced from a turret lathe will be rapidly made, and with form tools such as I describe, will enable inexperienced operators to produce accurate work in rapid time.

The form tool shown in Fig. 1 will obviously have to be held in an offset tool holder on the turret lathe; one that can be adjusted for center distance to suit the size of work to be produced. Inasmuch as the product in this particular case is of brass, the form tool will be made out of carbon steel, preferably a nonshrinking and nonchanging steel such as Ketos, or any other steel on the market with the necessary properties. If it is impossible to secure steel of this class, extra caution should be exercised in hardening owing to the shape of the form tool, as the contractions taking place in a tool of this type when same is hardened will very often result in a crack or a total break.

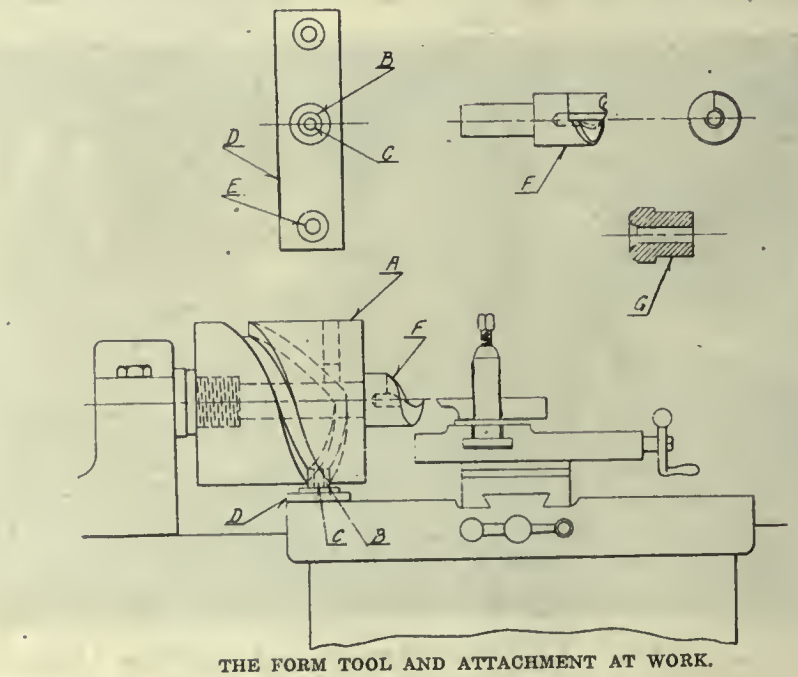
The writer has had considerable experience with this type of form tool and after considerable grief in the way of broken tools finally resorted to the following method of hardening, where ordinary carbon tool steel was used, which proved successful in almost every instance. Heat the tool up to as low a heat as it will harden under, then dip it in warm salt water until the vibrations can no longer be felt in the tongs; after which put the tool in oil.

The form tool is first turned up in the lathe and faced square on the working end. A hole is drilled in the center, as shown so as to provide clearance for the cutting tool. One-quarter of the tool is cut away in the miller so as to provide room for the master tool to back out of the way. After the blank is milled out, it is put into the cam chuck adapter and secured from turning by a set screw. The cam is screwed on the spindle of the lathe, and this cam operates the carriage back and forth by means of the roller (b) which rides on a shouldered stud (c). This stud is fastened in the center of a strap that spans the lathe carriage and is fastened thereto by cap screws.

The compound rest is set parallel with the ways so that it can be used for feeding longitudinally. A lathe on which the rack and pinion can be disengage is most suitable for this class of work so that no drag will be put upon the carriage. It is sometimes found advisable to have a tension of some kind taking the slack out of the carriage and roller engaging with the cam. The rise of the cam is enough to give cutting clearance on the forming tool.

A committee is now discussing ways and means for the proposed new county hospital to be built at Simcoe, Ont.

The erection of a fourteen-storey building at the corner of Bay and Temperance Streets, Toronto, is being planned by the York County Athletic Club. The plans are well under way, and the estimated cost is $2,811,000.



THE FORM TOOL AND ATTACHMENT AT WORK.

Would You Like to Receive One of These Scales FREE?

You can easily do so and at the same time add to your store of knowledge by entering our weekly contest of which details are given below.

The scale is 6 in. long and is made from finest quality steel. One side is marked in 32nds, the other side in 64ths. A table of decimal equivalents is also stamped on one side, and a table of tap drill sizes on the reverse side. This scale is well worth securing.

What You Have to Do

We publish every week a number of interesting facts or statements selected from the advertising pages for that week. The selections for this issue are given below. Read these through, then turn to the advertising section and see if you can pick out the advertisements to which they refer. The work is interesting, it will train your powers of perception and of memory, it costs you nothing, it will make you better acquainted with the various lines of machinery and tools in the market, and with perseverance you are bound to win one of these useful scales as a prize.

The Lucky Prize Winner for Nov. 11th Issue List is FRANK WALSH, 93 S. Bentruck St., Sydney, N.S. He Had All Answers Correct.

CONTEST FOR DEC. 9TH ISSUE

Contestants are required to write us, stating to which advertisements we refer to in this number.

1. Something that has four heads. Oh, no—it's not a man. What is it?
2. Something that has been accumulating for over sixty years.
3. How to secure prompt shipment of a certain product which is made in all standard sizes.
4. How to overcome the present power shortage.
5. Something that is at your beck and call.
6. How to keep track of every heat treating operation.
7. How to produce exact work in record time.
8. A company that produces a product in Canada different from anyone else.
9. Something that your lips never touch.
10. A product that will withstand heavy pressure without increasing its temperature.
11. A machine that can cut pieces up to 120 inches diameter.
12. How to secure the reward of greater production.

These are Correct Answers for List from Nov. 11th Issue:

1. H. W. Petrie Co.
2. The National Acme Co.
3. L. S. Starrett Co.
4. Bilton Machine Tool Co., and Fisher Motor Co.
5. A. B. Jardine Co.
6. Union Mfg. Co.
7. Clipper Belt Lacer Co.
8. R. McDougall Co., Ltd.
9. Holden Co., Ltd.
10. Norton Co. of Canada.
11. Canadian Machinery advertisement.
12. Canadian Driver-Harris Co.
13. Brown & Sharpe Mfg. Co.
14. Clemson Bros., Inc.

Closing Date for This Contest is December 30th

WHAT OUR READERS THINK AND DO

John Conley Gets Some Planer Experience

Planing Thin Work, Curves, Locomotive Links, Irregular Shapes, and Spirals, are a Few of the Problems.

By J. DAVIES

JOHN has found out, that to "pack all your troubles in your old kit bag" is not the way to get them solved, not in a machine shop anyway. He prefers to share them with the other fellow, so that when he had a thin plate to plane all over on both sides, and found that it was too big for the vise and he couldn't put plates on the top because he had to plane the entire surface, he simply made tracks for Tom Clark, an old planer hand, and asked him for advice.

Tom came over to John's machine and examined the job critically and then said, "I should advise you to hold it down with toe dogs and use the Johnny blocks to get the size." "Quit your fooling, what's a toe dog and a Johnny block?" "In a job like the one you have, there is only two ways to fasten it down that I know of. If the plate is thick enough and holes in the sides of the plate are no detriment to the job, we generally drill holes and use what we call finger clamps, some call them toe clamps."

When it is undesirable to drill holes in the work, toe dogs are usually resorted to. This equipment consists of pieces of wrought iron or steel made to fit the slots of the table, with a hole drilled and tapped at a slight angle to receive a set screw. Pieces of steel of a suitable length are ground, one end with a ball point to fit the cupped end of the set screws, the other with either a chisel or centre punch end to press against the work. Care must be taken that the angle of the toe dog is not too great—the angle of the tapped hole is usually 8 or 10 deg., just enough to insure that the dog will press the work hard down to the table. When using toe dogs, stop pins must be used to prevent the work slipping on the table."

"I understand you now, but what about the Johnny blocks?"

"Johnny blocks is a shop term for Johanson precision blocks. They are simply blocks of steel, hardened and ground very accurate and can be built up to any size. They are very useful to get your sizes on the planer."

"How do you use them?"

"How thick is this plate to be finished?"

"Three-quarters of an inch."

"Well, simply get a block that is ¾-inch. thick, place it on the table and set your tool to just touch it or to pinch the thinnest piece of paper you can get, or if you have a job with a number of sizes get the blocks to correspond to the different heights and set your tool or tools to suit the blocks. I find them very useful and accurate.

"I will have to go though, for my cut is nearly over, still there are one or two other things you want to look out for. When you lower your cross rail, lower it as close to your work as you can and if you have an important job on, test if it is parallel to your table with the indicator. Put your tool in straight so that if it should happen to move it will swing away from your work and not dig into it."

"Thanks very much, perhaps I may be able to do something for you some day."

"Oh, that's nothing, if you are interested come round to my place some evening and I will tell you of some of the unusual planer jobs I have seen."

"Righto, how would next Monday night suit you?" "It suits me all right." "All right, I'll be right there."

Some Interesting Tales

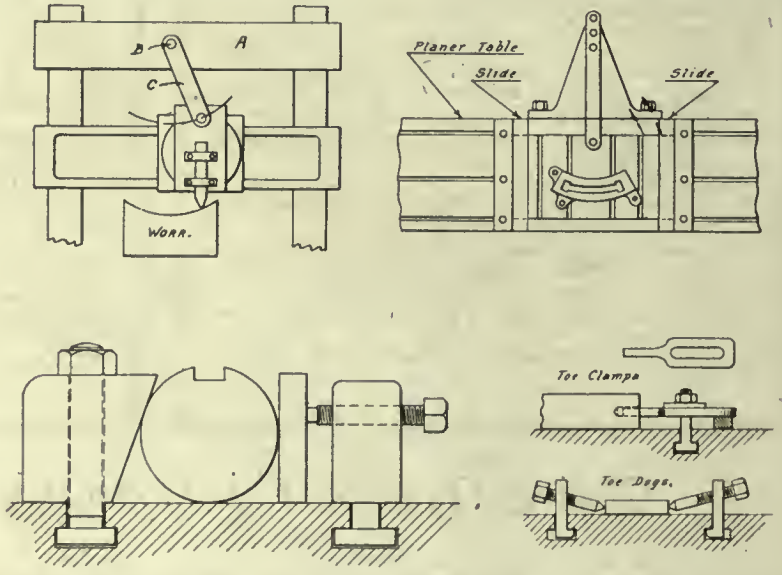
On the following Monday evening John duly presented himself at the home of Tom Clark and found him deeply engrossed in the pages of Canadian Machinery. Although Tom was a regular old timer he kept himself informed of all the latest developments of the trade and could relate some interesting experiences. When they were comfortably settled down John said, "Now, Tom, what do you consider your most interesting planer experience?"

"I don't know, but probably planing some taper radial sections for a swing bridge." "Do you mean to tell me you can plane a radius or a curve? I thought a planer was for straight work only."

"Sure thing, you can do all kinds of things on a planer if you have the attachments. When I was working at the Canada Foundry they planed all the links for the Canadian Northern locomotive that they were building."

"How did they do it?"

"In planing links such as are used for locomotives, the tool is stationary except for the downward feed, and the



SOME LESSONS ON PLANING CAN BE LEARNED FROM THESE SKETCHES.

work is made to travel through a curved path. This is accomplished in several ways. The most satisfactory is where the work is bolted to an extra table held between strips, which hold it from moving lengthwise on the table, but allow it to travel transversely across the table. Attached to this extra table is a bar with a hole in it the required radius. Through this hole passes a pivot pin, which is fastened to some secure support. If it is a very large radius which requires but a very slight cross motion of the extra table and necessarily a very long arm, the support for this pin would probably be on a special concrete foundation of its own. If the radius is a very small one and the pivot pin must be close up to the planer table, it can be very conveniently supported by a bracket bolted to the side of the planer.

"As the table moves backwards and forwards, the extra plate to which the work is fastened rotates about the centre of the pivot pin, and in so doing slides backwards and forwards across the table. Where frequent variations in radius occur, the link may be slotted and the pivot pin adjusted to different radii, as shown in sketch."

"Another radius planing job is to plane a casting to sit on a boiler, where the curve would have to be the same radius as the boiler. This is a little different from the link planing attachment. In the link planing attachment the work was made to swing to a given radius. In this attachment the tool is made to swing in a given arc. If the construction of the planer is such that it is not convenient to bolt your attachments to the housing direct, a bracket A is bolted across the housing B, and carries an arm C.

"One end of the arm C swings on a pin attached to A and the other end is pivoted to the tool slide. The feed screw is removed, which allows it to slide up and down freely. After the work and the tool are properly set the planing is done by simply feeding the saddle along the cross rail. The horizontal movement causes the tool point to follow a radius equal to the length of arm C, which is made to suit the required radius. This type of attachment can only be used when it is a true radius that is required."

"Does that mean that it is only possible to plane to a true curve?" "Oh, no, not by any means. By making a template the shape required, an irregular form, convex and concave, can be produced. The template is bolted to the cross rail by any convenient attachment, this, of course, would depend upon the construction of the machine.

"The template is made with a slot in it and a roller that is attached to the tool slide is made to fit this slot when the saddle is fed horizontally along the cross rail, the tool slide moves up and down and conforms to the shape of the template, thus producing the shape of the template on the work."

A Planer's Varied Uses

"Isn't it surprising the variety of work that can be done on a planer?" "I should say so, why in a case of emergency I have seen them cut gears on a planer." "How were they set up?"

"The gears were put on a mandril and a bracket containing centres was bolted to the planer table, and a gear, a small gear would do if it had the same number of teeth, put on the same mandril. A spring finger was made to fit the space in the index gear and bolted to the table so that the number of teeth could be correctly spaced." "Wouldn't it be handier to do all those kind of jobs on the miller?"

"Generally speaking, yes, but occasionally the planer is the best. I remember a case in point, the Elliott paper box factory wanted some corrugated rolls made, such as they use for making corrugated paper. The planer was the only machine long enough to do the job so the superintendent fitted up a milling cutter with a suitable bracket to the cross rail and devised a special slow forward feed with a worm and worm wheel arrangement. This could be thrown out of gear with a lever and the table run back at its ordinary speed at the end of every tool. The roll was about 64 inches long.

"Another interesting planing attachment is used at Grey's in Toronto. They not only make corrugated rolls for flour mills there, but special corrugations too. In cutting spirals, a clamp is fastened to the work with the end extending across the table. The end of this clamp travels up and down an inclined plane that is fastened to the housing of the planer and is kept in contact with it by a suitable weight. As the table travels backwards and forwards, on account of the inclined position of the piece bolted to the housing, it forces the work to make a partial revolution with each stroke of the planer. By varying the angle of this bar the amount of travel on the work can be regulated. The steeper the angle formed, the steeper will be the pitch of the spiral. The planing is done with a tool formed to the desired shape. The right number of spirals can be obtained by a ratchet wheel arrangement which can be made to move any number of teeth each stroke of the table.

"Another very useful attachment for a planer is a pair of vee blocks, and by the way, the planing of a pair of vee blocks involves a principle that may be very useful to you. First plane a tongue on the base of the two blocks to fit one of the slots in the table, fasten the two blocks in position, set over the head to 45 deg. and take a cut off. Then without moving the angle of the head or position of the tool, turn the blocks round and take a cut off the other side. This ensures that they will be both alike, equal angles, and will be in line at any part of the table. Round stock is also held by means of a special planer strip. This strip has a tongue on the base to keep it in a line and it has an angular face so that the pressure on the shaft forces it down upon the table, but enough for one night."

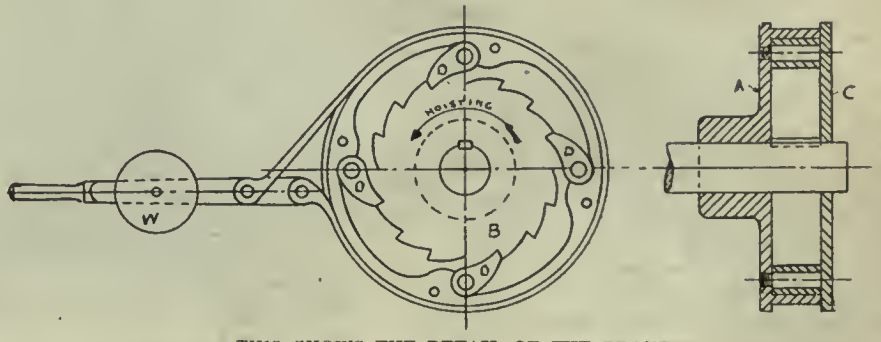
In a communication by the Director of Mines, U.S.A., to the "Journal" of the Franklin Institute, it is recommended that carbon tetrachloride fire extinguishers should not be used on fires in confined spaces by persons who are not protected from the gases arising or who are unable to escape from the immediate vicinity of the fire at once after applying the extinguisher. The following gases, it is stated, are generated when carbon tetrachloride liquids are vaporized: Phosgene, one of the most poisonous gases used in warfare, chlorine and hydrogen chloride. The vapor of carbon tetrachloride itself is a dangerous anaesthetic. It is only in confined spaces, however, that dangerous concentrations of these gases are produced.

EFFICIENT BAND BRAKE

By G. Wilson

The accompanying sketch illustrates a band brake that can be used for a great variety of purposes. The principle of the brake can be readily seen. The main casting A carries the pawls D and is free to move on the shaft. When hoisting, the racket wheel B is revolving only.

To release the weight, W has to be lifted; C is merely a cover plate fastened to the main casting by small screws.



THIS SHOWS THE DETAIL OF THE BRAKE.

DEVELOPMENTS IN SHOP EQUIPMENT

POWER PRESS BROACH

The Hercules Machinery Co., Detroit, Mich., have placed on the market a power press broach which is illustrated herein.

The working elements consist of a ram to which motion is transmitted by means of gearing which is controlled by a single lever through a system of friction clutches. The ram is a high grade steel rack, cut 4-5 pitch, and ground perfectly true with removable hardened steel head, and key-seated the full length, insuring perfect alignment. All gears are cut stub tooth, 20 degree pressure angle. This press broach is exceedingly simple, sturdy, powerful and convenient, and does by power a large variety of operations requiring pressure, such as forcing arbors, bushings, shafts or pins in or out of holes, seats into valves, linings into pumps, etc., straightening or bending, forming, sizing holes with hardened plugs, testing castings, sealing valves for testing, expanding babbitt bearings, etc.

It is an efficient tool for all broaching operations, and is designed for rapid quantity production, and can be conveniently placed for different operations on any assembling conveyor line. The knee can be removed and replaced with other fixtures that might be required for different draw or push broaching or other operations. The three speeds of the Hercules power press broach are all handled with the movement of one lever. By the upward movement of the lever the "quick-return" speed is obtained. By the inward movement of the lever the "fast down" speed is operated, while the downward movement of the lever gives the slow or pressure-down speed. The hand wheel is for use only when setting up some operation requiring close adjustment. An automatic throw-out also forms a part of this outfit, and this throw-out has the same effect as the automatic stop on a screw machine and permits the operator to set and govern the travel of the ram. The knee of this press is carefully fitted to perfectly machined ways with a shear pin support, making it impossible to overload and thereby avoiding all breakage. Not only is the shear pin a safety factor, but in the event of extreme overload the clutches would slip before b cakage could occur.

BENCH DRILLING STAND

The Black & Decker Mfg. Co., Baltimore, Md., has placed on the market a bench drilling stand as illustrated. It can take from ⅜-inch to ⅞-inch portable electric drills of this company's design, and they can be quickly detached when desired.

The bracket carrying the drill can be raised or lowered on vertical column and is secured in any desired position by means of split collar and clamping screw. Drill may be swung clear of base, making it possible to use this stand for such work as applying ring gears to automobile axles, drilling in the ends of shafts, and other work too high to be drilled on the bench. Both vertical and horizontal adjustment are secured by means of the clamping screw.

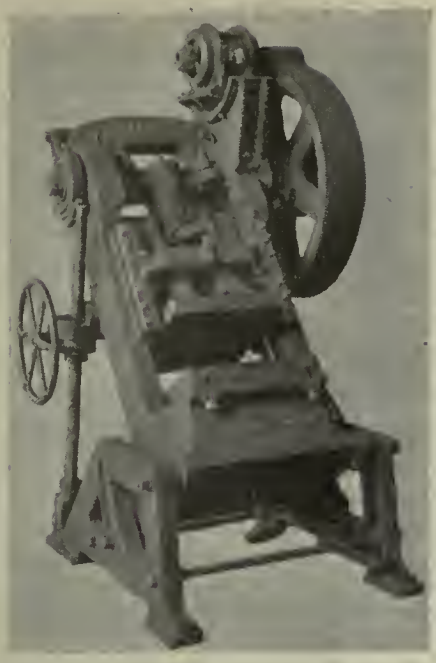
Extra long feed lever gives feed ratio of 6 to 1. 100 pounds pressure applied to handle feeds drill under 600 pounds pressure. In the base are six tapped holes to accommodate half-inch studs, used to clamp work in place. One stud with nut and clamp is supplied with stand. This bench drilling stand is said to be exceptionally rigid, all parts being of unusually generous size. For instance, the vertical column is a solid steel shaft 1 7-16 inches in diameter. Base is provided with four holes for fastening stand to bench. Four ⅜-inch lag screws are supplied.

Following are some interesting dimensions: Height (bottom of base to top of vertical column) 30 inches, vertical adjustment of drill 12 inches, drilling radius (distance from centre of drill bit to circumference of vertical column), 7 inches, horizontal adjustment of drill 360 degrees, feed (vertical travel of drill when operated by feed lever) 4 inches.

INCLINABLE PRESS

The Toledo Machine & Tool Co., Toledo, Ohio, have placed on the market a straight column press that possesses several unique features. Reference to the photograph will show that this press may be used in either an upright or inclined position by simply turning the hand wheel. It is also entirely self-contained, being driven by a direct connected electric motor. Attention is called to the

VIEW TO LEFT DEPICTS POWER PRESS BROACH. THE ILLUSTRATION TO RIGHT SHOWS BENCH DRILLING STAND.



GENERAL VIEW OF THE PRESS.

motor bracket which is so arranged that it always keeps the motor in a vertical or upright position no matter whether the press is upright or inclined to any angle within its limits. The pinion is always in mesh.

The distance between the uprights is somewhat greater than is ordinarily furnished on a press of this size. The slide is of liberal proportions and is carefully guided in substantial gibs, to insure the greatest possible accuracy.

The makers state that this machine can be furnished with or without gearing and with or without the bar knockout in slide and the direct connected lower liftout, as well as with or without the motor bracket. It is also built with the frame arched out from front to back and with an opening 14 inches wide in each housing to permit of feeding the stock from right to left or vice versa. Following are its principal specifications:

Weight as shown, 6,500 lbs. Bed, 24 x 23 inches, Bottom of ram, 21 x 19½ inches. Opening in bed, 12 x 12 inches. Distance between housings, 24 inches. Stroke, 2 inches. Distance from bed to ram, stroke down and adjustment up, 13 inches. Thickness of bolster, 3 inches.

ELECTRIC GENERATING APPARATUS

The Dodge Manufacturing Co., Mishewaka, Ind., have placed on the market an electric generating apparatus that is of rather interesting design. The photograph herewith shows clearly its general construction, and this outfit consists of complete power units for electric generating. Tests have been made on these units in strict accordance with the rules adopted by the American Institute of Electrical Engineers.

The generating units are made up either direct connected or belted in all standard voltages using Dodge heavy oil engines as motive power. The sizes manufactured at present range from 12½ h.p. to and including 75 h.p. The wide range of sizes in these outfits makes the fact evident that the power units are equally adaptable to either marine or stationary power plant service.

Oil Engine Used as Prime Mover

The heavy oil engine used is said to be sufficient guarantee of low cost operation, which of course results in a great saving in the cost of current generation. The engine is sold under a standard guarantee which specifies a consumption of fuel oil of .5 lb. per B.H.P. hour, using fuel as low as .28 Baume, containing not less than 18,500 B. t.u. per pound. It is said that every engine turned out must use less than the amount guaranteed on actual brake test; otherwise such guarantee could not be made with any degree of safety.

The engine illustrated has a brake output of 50 h.p. and is direct connected to a 30 K.W. 220 Volt D.C. generator, running at a normal speed of 425 R.P.M. It would therefore use 10,000 gallons of fuel oil per year, if operated 10 hours a day under full load for 300 days. This fuel costs on the average of 5 cents a gallon and would mean a total of $500 for annual fuel cost. This reduces the fuel-cost of current to $.005 per K.W. hour.

Construction of Generator

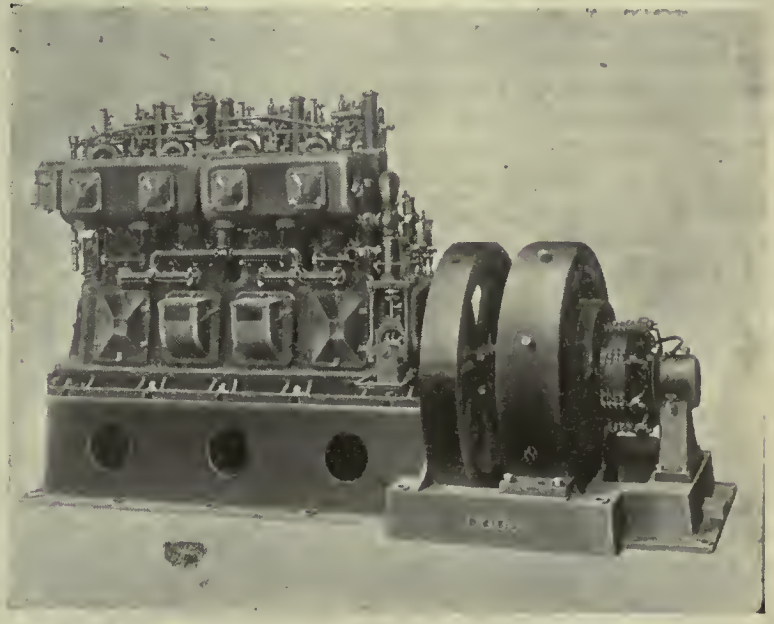
The generator used has been developed especially for this particular service by the Engberg Electrical & Mechanical Works at St. Joseph, Michigan. The armature is of the iron clad ventilated type, with laminated core, being built of electrical sheet steel, thoroughly japanned before assembling. The drum and core are provided with air ducts, permitting a thorough circulation of air through same.

Nothing but the very best double-covered magnet wire of the highest conductivity is used, and the insulation is thoroughly waterproof. A very desirable feature in connection with the armature is that it has been so designed as to eliminate a coupling on the armature shaft, the crankshaft coupling is direct connected to the armature drum, by such construction that the engine drives through the armature and not on the armature shaft. This method of construction is very substantial and makes it very easy to remove the armature—in fact this can be done without disturbing the engine in any manner whatever. Close regulation is assured by having the flywheel of the engine located close up to the armature and on the same end of the crankshaft.

The commutator is made of copper bars, insulated with the best grade of mica plate and is very heavy, thus insuring years of continuous operation without need of renewal. It is built up on a separate sleeve and bolted to the armature drum, so that the shaft can be removed without disturbing the windings. The bars are collected in a steel chuck, especially designed for this particular purpose, which is provided with large steel screws. The chuck is heated and allowed to expand, at which time screws are tightened to the very extreme. When the chuck cools and shrinks, the commutator is drawn into a perfect and lasting position.

Every part of both the engine and generator is of the highest possible grade in regard to material, workmanship and design. All bearings are extremely large and accurately fitted, thus assuring smooth and constant operation with comparatively little attention.

Both engine and generator are carefully tested and inspected at frequent intervals during the course of construction. Both are mounted on a heavy cast iron sub-base and dowelled in place, after which they are subjected to a final operating test under load.



GENERAL VIEW OF THE GENERATING APPARATUS.

The British Empire Steel Corporation

THE British Empire Steel Corporation has not yet become an accomplished fact. The proceedings were started months ago by which several Canadian companies were to be brought together, and in future operated in line with others in the Old Country.

There have been violent changes in the stock market value of many of the holdings that were to have been included in the merger in the first place, and it has been possible several times to go into the market and buy these securities at a less figure than that at which they were to be included in the Corporation.

It is probable that there will have to be considerable alteration before the British Empire Steel Corporation is successfully handled by the underwriters. There has been a lack of information in several lines that has hindered the work and shaken the confidence of Canadian investors who were identified with the plan in the first place.

Several of the leading companies in the plan of reorganization have become so far committed to the proposal that it is unlikely that anything approaching the disruption of the plans will take place, but it seems not only desirable but necessary that there should be a new basis worked out before the plan can be successfully consummated.

Looking to the future, the iron ore deposits, the coal beds, and the limestone of the eastern section of the Dominion should form a rare combination in the carrying out of industrial dreams of promoters and workers. The situation is unique, right on the seaboard and with ready access to the markets of the world.

If, with all that, they cannot in time turn out steel in competition with the steel companies of the world, there must be something wrong that does not appear on the surface.

Exchange Rate Again

THE exchange rate is again at a point where it is causing serious thinking, during the past few days it having touched 15 per cent. on several occasions. It is not an uncommon thing to hear of buyers asking for the longest possible period of time in which to settle for shipments from United States, not because they have not the means to make payment, but because they hope for a better turn in the exchange situation, and the gaining of a few points will mean quite an item to them.

Others, again, have been fooled by doing this thing. They have held off to the last, hoping for a more favorable rate, only to find that instead of coming down the rate of exchange has been going up, and that each day delayed has cost them more money instead of saving them a few dollars as they had hoped.

It is no doubt desirable that we should sell more to United States and buy less from the people there. That, in theory, is very good, but the fact is that there are many things, especially in the world of iron, steel and machine tools that we must secure there or at other points outside this country.

YOU may stay out of the market so long that prices will have touched bottom and started on the way up again before you act. Staying out of the market is a doubtful way of making a success of anything.

* * *

LESS than a year ago a man with a pile of steel sheets in his yard was sitting on them surrounded by a shotgun and an axe for fear some one buyer would insist on taking the lot. Now said buyer can come in unmolested and take the heap.

What the Business Papers Say

Time for Them to Get Together

"Syren and Shipping."—The question is, as has been rightly remarked by Mr. Launcelot E. Smith, the chairman and managing director of Smith's Dock Company, not one of asking the men to accept low wages. If they will look after production, wages will look after themselves. If, he says, the British working man and the British employer will get together they can beat the world, but the men are hampered by their unions and the employers by their federations. When an employer of Mr. Smith's character talks in this strain, our opinion is confirmed that it is up to both sections to tackle this grave problem in earnest, and at once.

Says Men Value Their Jobs Now

"Iron Trade Review."—Workmen have begun to value their jobs again and it is well that they may for their own good. Trade depressions are great stimulants to individual efficiency. Under such conditions only the really efficient may be reasonably sure of their jobs, this as workmen, or their ability to compete, as manufacturers. The working out of the law of practical economics now is to be seen on every side. In the end it means restored prosperity to the machine tool and other industries.

About the Power of the Future

"Power."—It is no longer a problem where to find a market for oil, but where to find the oil to supply the market. What are we going to do regarding our oil supply? Shall we wait until it is exhausted, as is the supply of natural gas, when it will be too late to act, or shall we join with the rest of the world in drawing up a world policy to safeguard the future?

Criticizing English Motor Cars

"Engineering."—It is, of course, a purely commercial question whether or not this is a wise policy, and it may be that there is room for all these expensive machines, and that more profit may be made in selling a few large cars than a greater number of small ones. Even this seems doubtful, for the number of people who are at the present time prepared to spend very large sums on motors is probably not great, and the moderate-priced machine has improved so much of late years that there is not such a very great gain in having an extremely expensive one.

A Difference in Methods

THE "Railway Age" gives statistics of the operation of American and British railroads during the first six months of 1920. The article was prepared by the Bureau of Railway Economics and the figures regarding the British railroads are the first of the kind ever available.

The average freight rate per ton per mile on the British railroads, which are still under Government control, was, in the first six months of the year, 26.3 mills, exclusive of charges for the collection and delivery of freight to and from the railroad stations. The average rate on American railroads in the same period was 9.7 mills, or about one-third as great.

The principal reason why American railroads can haul freight at an average rate only one-third as great as that of the British railroads is that they handle it in so much larger units—that is, in so much larger carloads and train loads. The average number of tons carried in each train by the British railroads was only 150, while in the United States it was 710.

The average number of cars in each freight train in England was 35, which is about the same as the average number of cars in an American freight train, but the average load carried in each car in England was only 6 tons, while in the United States it was about 28 tons.

It was, of course, this great difference in the average number of tons carried in each car which was chiefly responsible for the much larger number of tons carried in each train in the United States.

On Bein' the Boss

IN years when things was movin' fast and cash was stalking 'round, when clinkin' dimes and nickels was an ordinary sound—I used to think in them there days before we felt a pinch, that bein' the boss around the place was one outstandin' cinch.

Why, say, we never worried much, things seemed to hump along, with everything a-breakin' right and nothing ever goin' wrong.

His golf friends came in after lunch to coax him from the scene, to go and whack the little pill and clod-hop on the green. He gave his orders right and left, by heck, it was a cinch, this job of bossin' on the works before we felt the pinch.

And I looked forward to the day when they would pussyfoot to me, and say, "young man, this job of boss is henceforth handed unto thee."

Ah, then I would sit down in ease, a rift of wisdom on my brow, I'd keep an auto and a farm, a bacon hog, likewise a cow. My feet I'd plant upon the desk, my wealth would prosper inch by inch—oh, bossin' the whole shootin'-match would be to me a pleasant cinch.

But since things aint so fresh just now as they was 'bout three months ago, I'm not so certain of the fun of bein' the boss around the show. Some funny things turn up these days between the mornin' and the night, and I hear them tellin' round the plant that money's gettin' powerful tight.

The boss aint quittin' early now, he's settin' tight around the place, they're stickin' grey hairs in his head and plantin' wrinkles in his face. There's papers piled upon the desk, enough to fill a good-sized cart, and he's figurin' this here thing and that, and squintin' hard upon a chart. He's sittin' there long after dark, and says we aint a-goin to bust, but he's puttin' on the pressure there and changin' off from may to must.

I use to think that bossin' job was one grand, easy, fat affair, but I aint a-hankerin' for them now to lead me forward to his chair.—Ark.

The Retroactive Award

THE manner in which retroactive wage awards work out in some cases makes a hardship that is very difficult for the company against which the award is made.

For instance, such an award was made in the case of the Nova Scotia Steel & Coal Co., in the case of the miners, and by the award the increase in the cost of producing a ton of coal was about $1.25. This does not mean that the miner got that amount extra for digging a ton of coal, but that the combined increases paid to the several men who handle the coal from the time it is taken from the working place in the mines until it is loaded and ready for shipment amounted to the $1.25 per ton on the output of the mine.

The wage award was made retroactive over a period of two months or so. The company, in some of its contracts covering the sale of coal, have a clause which makes the customer liable for this increase, and in such cases it is possible to recover the increase for these sales, but a great deal of coal is sold in the open market without any such clause.

When a manufacturer buys coal he uses it for his steam plant, it goes into the manufacture of some line, and is passed out to the trade in this way at a fixed price. The manufacturer has no chance to recover on the increase he has to pay, for his goods have been sold.

The coal company used at that time about sixty per cent. of its coal for its blast furnaces and open hearths, and the coal product was being sold to the customers of steel at current prices, with no string tied to the sale by which the buyer might find himself liable to an extra tax some two months after to pay for the increased cost of coal used in making the steel. In this case the coal company had no come-back.

An award that is made retroactive as a general thing leaves the company no chance to adjust its selling prices to meet the changed conditions, and is apt to impose a burden on its financial strength that it may not be able to bear without having to curtail seriously in some other direction.

THE scrap iron market is variously described by dealers as stagnant, dead, inactive, listless, lifeless, rotten, uninteresting, etc., Now, if any of our dear readers have a phrase that will nicely sum up these opinions, will he kindly shoot?

"I Wonder If he Has Really Reformed?"

MARKET DEVELOPMENTS

Buying Should Be Better in the New Year

Tool Buyers in New York Claim They Will Not Come Into the Market Until January—The Premium Market Has Simply Ceased to Exist—Exchange Once More a Serious Matter Here.

ONE might very well imagine that matters were dull indeed in the machine tool markets, and in the steel trade generally, were it not for the fact that occasionally a dealer comes along who has landed a very respectable order, and that at his regular price, without any special consideration. In the steel market it is to be expected that trade will be small in volume between now and the first week in January. The trade has always found it that way, and this year is no exception. Boiler tubes are much wanted just now, and that is the one line that moves best at this season. As soon as the boats tie up for the season work is started on repairing.

The exchange situation is again causing some serious thinking on the part of firms having shipments coming from United States points. They are in many cases asking for the longest possible time in which to take up the payment of their bills, hoping that the rate will turn a little in their favor. Some of them have been fooled by the recent rise, and their delay has cost them money instead of saving any for them.

The premium mills are getting very little business from the Canadian territory just now. In fact the premium market has ceased to exist. It may be some little time before the buyers here will get the full advantage of cheaper steel and iron.

The scrap metal market does not improve at all. Buyers are remaining out of the market. Dealers are not buying anything to speak of unless they have some contracts that have to be filled.

MONTREAL LOOKS FOR BETTER TRADE SHORTLY AFTER FIRST OF THE YEAR

Special to CANADIAN MACHINERY.

MONTREAL, Dec. 9.—Business at the present time seems to be regulated more by financial conditions than by the general trade requirements. There is little doubt that trade in general would be more brisk if the difficulty of financing was less pronounced. The problem of economic adjustment is one that requires considerable initiative and courage on the part of the manufacturers, as under existing conditions it necessitates carrying on, either at a loss or foregoing all profits during the period of clearing out old stocks and replenishing at the new basis. Even this policy is enshrouded in great uncertainty, as the declining prices offer little guidance as to the ultimate stopping point. This influences the trade to such an extent that buying all along the line is curtailed or restricted to the point that stocks, which normally would be disposed of in a reasonably short time, are carried over, with the result that further buying is postponed, the consequence being a temporary suspension of activity in many lines of industry.

Local Price Revision Expected

The revision of American steel prices to lower levels has not resulted in any pronounced activity on the part of consumers. It will probably be some little time before mills are turning out steel at the new base, but the movement of price reduction appears to be general and it is now a question whether the lower quotations will open the channels for renewed business. "We are now in a period when it is usually expected that business will be slack, and at the present time this dullness is emphasized, particularly when compared with that of the past several years, when the dull pre-winter months differed very little from other periods of the year. However, when the present is compared with corresponding months in pre-war days, there is very little to show where a striking difference can be drawn." This statement by a dealer here indicates that general business is quiet, but that too much stress is placed on the relative falling off between the activity created by abnormal world conditions and those which should obtain had the commercial trail been blazed in the ordinary peaceful manner.

"It is logical to suppose," continued the dealer, "that a transient period must be passed through before a sound working base can again be established, but this will slowly right itself, and probably before spring we will see a healthy revival of industrial enterprise, but it is only after the tide begins to rise that full confidence will return and open the way to renewed activity. We are anticipating a revision of prices, but it will probably be the first of the year before these changes will be announced. It will be some time before American prices will affect this market, and in the meantime we will continue to quote present prices on warehouse material."

Little Demand for Machine Tools

General lessening of activity throughout the district has reacted to some extent on machine tool dealers, as reports are to the effect that business is more than seasonably quiet. In some respects it may be stated as exceptionally dull. Many of the factories in this locality have made reduction to their operating staffs, and while nothing definite can be learned as to the duration of curtailment, it is not thought likely that any marked effort will be made to replace or install new equipment until business has again resumed some of its former activity. The problem of selling machinery and supplies is becoming real work, as users are not as easily persuaded to the advisability of renewing tools. This attitude on the part of the consuming trade will likely mean a period of several months when buying of equipment will be restricted to the most urgent needs. Manufacturers realize that early adjustment is imperative, and this condition, while temporarily holding trade in suspension,

must obtain during the transition period. Dealers are far from being pessimistic on the future outlook, and many are confidently making plans for the coming year, in the hope and belief that before the spring the reversal of the tide will take place and the stability of the market be established. "We are a little reluctant to revert to former prices, but it is probably the best move after all, as such action is an essential factor in solving the problem of supply and demand. At the present time the trade is kept from buying by the weakening tendency of all commodities, a condition that is not conducive to active buying." This remark from a dealer apparently explains the prevailing dullness in many quarters.

Regular But Light Movement

The metal situation is keeping step with other lines of activity in gradually relinquishing the high hold on prices that have been the order of the day for many months. These lower quotations are the result of trade adjustment as much as to the falling off in demand. There is still reason to believe that solid ground has not yet been reached and further sinking will likely be reported. Local quotations show a further decline this week. Tin and aluminum are down one cent, the quotations being 44 cents and 34 cents respectively. Other ingot metals are down from ¼ to ½ cent per pound; electro copper is now 18½ cents, spelter 8½ cents, lead 7½ cents, and antimony 8 cents per pound. Movement of metals is light but quite regular.

Interval of Inactivity

Old materials are in a position where the market is conspicuous by the entire absence of any active interest. Dealers are unanimous in stating that there is "nothing doing." This applies generally, with the exception of such local trading as is necessary to carry on the regular business of the foundries in the district. Even this activity has been below normal for some time. Dealers are not particularly interested in prices, as the small demand offers little opportunity of reselling the material, and therefore they are not desirous of accumulating any excessive stock in face of the weakening market. The prices quoted are a fair average of what dealers here are paying but actual transactions would probably be carried on at figures slightly lower.

THE EXCHANGE IS BOTHERING THEM

Buyers Like Long Terms on U.S. Goods to Take Advantage of Any Drop

TORONTO.—One might imagine that the machine tool trade in this district were very quiet were it not for the fact that now and then on the way around the machine tool houses good sized orders are heard of. There is business moving, although it is not as good as it was some months ago, and those who study matters carefully believe that it is going to be better shortly after the break of the new year.
